ROGOFF, BARBARA

1950–

Born in 1950, Barbara Rogoff received her B.A. in psychology with honors from Pomona College in 1971.

From 1971 to 1972 she attended the École de Psychologie et Sciences de l'Éducation at the University of Geneva, where she studied with Barbel Inhelder. In 1977 Rogoff received her Ph.D. in developmental psychology from Harvard University, where she was mentored by Sheldon H. White, Jerome Kagan, and Beatrice Whiting. During her graduate training, she spent a year in Guatemala as a field psychologist at the Institute of Nutrition of Central America and Panama, which began a decades long involvement with the Tz'utujil Mayan community of San Pedro, Guatemala. There she collaborated with the anthropologists Benjamin and Lois Paul. From 1977 to 1992 she was a member of the Department of Psychology at the University of Utah. In 1992 she joined the faculty at the University of California at Santa Cruz, where as of 2008 she was the UCSC Foundation Professor of Psychology. She is a Fellow of the American Psychological Association, the American Psychological Society, and the California Academy of Science, as well as a member of the National Academy of Education. She has been a Fellow at the Center for Advanced Study in the Behavioral Sciences and a Kellogg Fellow.

Rogoff has advanced theory and research on the cultural and social bases of human development. In 1975 she collaborated in a landmark study that examined the ethnographies of 50 cultural communities and documented a shift between 5 and 7 years of age in children's roles and responsibilities across these settings. This research contains two themes that came to be central to Rogoff's research: the cultural variability of child development and the developmental processes in these culturally diverse paths. In 1981 Rogoff drew on a wide range of anthropological and psychological research to describe how the cultural institution of formal schooling relates to cognitive development. She concluded that contemporary understanding of cognitive development is deeply entwined with children's experiences with formal schooling and, thus, limited in its ability to account for the range of human intellectual development.

From the 1970s into the early 2000s, Rogoff pursued these ideas in empirical research on memory, problem solving, planning, communication, and attention. She examined cultural contributions to development as well as how cultural ways of thinking are fostered in children through social interaction. This research, coupled with her ethnographic work in Guatemala, led to the concept of guided participation, a concept that pointed out that children's learning is based on their own participation in cultural activities, at the same time that other people and the community also provide them with varying forms of guidance. In one form of guided participation, learning through intent community participation, Rogoff described learning as children participate in the range of everyday activities of their community, in

Rules and Procedures

the company of more experienced cultural members. Although these activities are sometimes instructional, they often occur in the midst of adult activities in which the primary purpose is not to instruct the child but to carry out the activity. An important component of her approach is the idea that children are participants in cultural activities from the outset of development, in one form or another. For Rogoff (2003), intent community participation, in which children seek opportunities to observe, initiate, and engage in the activities that are important in their community, is one of the most prevalent forms of children's learning.

Rogoff's approach redefines development in a fundamental way with her view that the proper level of developmental analysis is not the solitary child but rather the child's changing participation in socially and culturally organized activity. This approach, integrating the social and cognitive processes of human development is described in her 2003 book, *The Cultural Nature of Human Development*, which was awarded the APA William James Award for advancing the field of psychology.

S

SCAFFOLDING

Scaffolding is an often-used construct to describe the ongoing support provided to a learner by an expert. In this entry, the original notion of scaffolding and its key tenets are discussed, followed by a description of the use of the construct in classrooms and in computer-based systems. The challenges of providing scaffolding to students in a classroom are also discussed.

Scaffolding has been defined by Wood, Bruner, and Ross (1976) as an “adult controlling those elements of the task that are essentially beyond the learner’s capacity, thus permitting him to concentrate upon and complete only those elements that are within his range of competence.” The notion of scaffolding has been linked to the work of Soviet psychologist Lev Vygotsky (1896–1934). However, Vygotsky never used the term *scaffolding* (Stone, 1998), but emphasized the role of social interaction as being crucial to cognitive development, so that learning first occurs at the social or interindividual level. Thus, when a child (or a novice) learns with an adult or a more capable peer, the learning occurs within the child’s *zone of proximal development* (ZPD). ZPD is defined as the “distance between the child’s actual developmental level as determined by independent problem solving and the higher level of potential development as determined through problem solving under adult guidance and in collaboration with more capable peers” (Vygotsky, 1978, p. 86). Enabling the learner to bridge this gap between the actual and the potential depends on the resources or the kind of support that is provided.

KEY FEATURES OF SCAFFOLDING

The original notion of scaffolding assumed that a single more knowledgeable person, such as a parent or a teacher, helps individual learners, providing them with exactly the support they need to move forward (e.g., Bruner, 1975; Wood et al., 1976). One of the most critical aspects of scaffolding is the role of the adult or the expert. The expert is knowledgeable about the content of instruction as well as a facilitator with the skills, strategies and processes required for teaching. The expert not only helps motivate learners by providing just enough support to enable them to accomplish the goal, but also provides support in the form of modeling, highlighting the critical features of the task, and providing hints and questions that might help learners to reflect (Wood et al., 1976). In this conception then, the adult’s role has perceptual and cognitive as well as affective components (Stone, 1998).

Although the role of the adult is crucial, descriptions of the notion of scaffolding (Langer & Applebee, 1986; Palincsar, 1998; Reid, 1998; Stone, 1998) point to several other key elements of scaffolded instruction:

1. *Common goal.* Shared understanding, described as *intersubjectivity* (Rogoff, 1990), is of critical importance in scaffolded instruction. Intersubjectivity refers to the combined ownership of the task between the adult and the child, and setting a common goal.
2. *Ongoing diagnosis and adaptive support.* Perhaps the most important feature of scaffolding is the fact that the adult is constantly evaluating the child’s progress and providing support that is appropriate for “*this*

tutee, in *this task at this point in task mastering*” (Wood et al., 1976, p. 97). This results in interactions that are different in “content and form from individual to individual” (Hogan & Tudge, 1999), and for the same individual at different times. As Wood and colleagues (1976) described, scaffolded interactions comprise of a theory of the task and a theory of the tutee. The adult needs to have a thorough knowledge of the task and its components, the subgoals that need to be accomplished, as well as knowledge of the child’s capabilities as they change throughout the instruction.

3. *Dialogues and interactions.* A critical factor in the ongoing diagnosis and calibrated support is the dialogic nature of scaffolding interactions, so that the learner is an active participant and a partner in deciding the direction of the interaction, and not a passive recipient. The dialogic nature of scaffolding is best illustrated in the reciprocal teaching studies of reading (Brown & Palinscar, 1985; Palinscar & Brown, 1984), in which students took turns leading the group discussion, engaging in comprehension monitoring strategies.
4. *Fading and transfer of responsibility.* The final feature of scaffolding is reducing the support provided to learners so that they are in control and take responsibility for their learning. The best scaffolding will eventually lead learners to internalize the processes they are being helped to accomplish (Rogoff, 1990). In the original description by Wood and colleagues (1976), the important aspect of the transfer of responsibility is that the child has not only learned how to complete a specific task, but has also abstracted the process of completing the particular task.

EXAMPLES OF SCAFFOLDING

The early studies that described scaffolding, be they descriptions of parent-child interactions (Greenfield, 1999) or classroom interactions (Langer and Applebee, 1986), were observational rather than interventionist studies. One of the earliest accounts of an interventionist study of scaffolding is Wood, Bruner and Ross’s 1976 study in which 3-, 4-, and 5-year-olds engaged in a task of building a pyramid from interlocking blocks, with guidance from a tutor. Each child was tutored individually and the tutor followed a set of guidelines for her tutoring. But the tutor did not always follow pre-set rules in her interactions; instead she provided just enough assistance to help the child move forward—assistance that was sensitive to, and adapted based on, the child’s progress. Wood and colleagues documented six types of support that an adult can provide: recruiting the child’s interest, reducing the degrees of freedom by simplifying the task, maintaining

direction, highlighting the critical task features, controlling frustration, and demonstrating ideal solution paths.

Perhaps the most well-known example of the notion of scaffolding in the classroom is the work on reciprocal teaching (Palinscar & Brown, 1984; Brown & Palinscar, 1985). In this study, groups of students were supported in the process of reading by strategies such as self-directed summarizing (review), questioning, clarifying, and predicting. A teacher or a more capable peer took the lead in modeling the strategies until students in the group could apply them on their own. The teacher or the peer modeled the strategies and used prompts and questions to enable students to apply the four strategies. As described by Palinscar and Brown (1984), the teacher used strategies such as prompting (“What question did you think a teacher might ask?”); instruction (“Remember, a summary is a shortened version, it doesn’t include detail”); and modifying the activity (“If you’re having a hard time thinking of a question, why don’t you summarize first?”) (Palinscar & Brown, 1984, p. 131). Both the Wood, Bruner, and Ross study and the reciprocal teaching studies highlight how the key features—intersubjectivity, ongoing diagnosis, tailored assistance, and fading—were attained in the dynamic, interactive environment. Whereas the study by Wood and colleagues illustrates the tutorial interventions in a one-on-one situation, the reciprocal teaching studies were conducted with small groups of learners. In addition, both the quality and the quantity of support were varied, based on the needs of a particular learner. As the learners attained competence, the scaffolding was faded, giving them more control.

SCAFFOLDING IN CLASSROOM SITUATIONS

The notion of scaffolding is increasingly being used to describe the support provided for students to learn successfully in classrooms, especially the use of project- or design-based activities to teach math and science (e.g., Kafai, 1994; Kolodner et al., 2003; Krajcik et al., 1998). Many of these approaches are based on a socioconstructivist model (Vygotsky, 1978; Wertsch, McNamee, McLare, & Budwig, 1980) emphasizing that learning occurs in a rich social context, marked by interaction, negotiation, articulation, and collaboration. The original notion of scaffolding, as used in the initial studies of parent-child interactions (Bruner, 1975) or in teacher-student interactions, focused on situations that allowed for one-on-one interactions between the adult or the expert and the learner. The one-on-one nature of the tutoring allowed the adult/teacher to provide “titrated support” (Stone, 1998) that changed based on the progress made by the learner. However, classroom situations involving many students do not allow for the fine-tuned, sensitive, personalized exchange that occurs in one-on-

one or small-group scaffolding (Rogoff, 1990). Therefore, instead of one teacher working with each student, support is provided in a paper or software tool that individuals interact with, or classroom activities are redefined so that peers can help each other (e.g., Bell & Davis, 2000; Jackson, Krajcik, & Soloway, 1998; Puntambekar & Kolodner, 2002; Reiser et al., 2001).

SOFTWARE TOOLS IN THE CLASSROOM

Software environments that provide support have been developed with the goal of supporting students in the processes that they might find difficult in a complex task when it is not possible for a teacher to attend to each student in a class. Several software tools have been developed to prompt students to reflect, articulate, and complete the steps of a complex task. Examples of such software include ThinkerTools (White & Fredrickson, 1998), Knowledge Integration Environment or KIE (Bell & Davis, 2000), Progress Portfolio (Loh et al., 1998), BGuILE (Reiser et al., 2001) and Model-It (Jackson, Krajcik, & Soloway, 1998).

Quintana and colleagues (2004) have put forth a comprehensive scaffolding design framework for building software tools to help students learn from inquiry-based science activities. Their framework is based on the difficulties that students have during science inquiry and focuses on such aspects of the inquiry process as process management, i.e., the ability to engage in processes and activities required for inquiry; sense making, which they describe as difficulties that learners experience in making sense of their work and finding a direction; and data recording and analysis and articulation.

Reiser (2004) proposed two mechanisms as being essential to software tools that scaffold complex learning: structuring and problematizing. Structuring is believed to scaffold students by decomposing the task and guiding them through the steps of a complex task. Structuring can be provided by using prompts that help students with reflection and articulation, helping them move forward in a complex task. For example, in the software tool Explanation Constructor (Reiser et al., 2001) is an electronic journal that helps students construct their science explanations. In this tool, structuring is provided for articulation and reflection by having students record their research questions, construct explanations, and articulate their findings. In other words, structuring breaks down a complex task into constituent steps to make it more manageable to students. Problematizing, as Reiser described it, "is the flip side of structuring" (p. 287). It involves having learners confront the complexity of the task by helping them focus on aspects of the task that need to be resolved. For example, having students analyze

their findings based on a theoretical framework forces students to think about the theoretical constructs that they should use in their explanations, supporting the notion of problematizing.

Software tools and frameworks are based on the difficulties that students have and help students with complex tasks and several strategies that they need. They provide an important first step in the design of scaffolding; however, if the tools do not fade the support, and do not vary the support for different users, they lack the most critical elements of scaffolding, that of ongoing diagnosis and calibrated support.

PEER INTERACTIONS

In addition to software tools, peer interactions have also been considered important for scaffolding in classrooms. In contrast to the adult being the expert in the traditional notion of scaffolding, in peer interactions students support one another through their interactions. Brown and colleagues (1993) emphasized the multidimensional nature of the interactions in a classroom embodying the communities of learners approach. In this environment, the researchers note:

[learners] of all ages and levels of expertise and interests seed the environment with ideas and knowledge that are appropriated by different learners at different rates, according to their needs and to the current states of the zones of proximal development in which they are engaged.

For example, a modified version of the jigsaw method is used in this approach in which a research theme is divided into subtopics and students in each research group are assigned different topics. Thus every group has a member who is working on a subtopic and every member in a group works on a different subtopic. All the students work on their subtopic and then students come together in reciprocal teaching groups to put their information together and complete the jigsaw. Expertise is therefore distributed amongst all participants, who are engaged in supporting and critiquing one another, justifying views and opinions, and offering suggestions and explanations. The teacher's role changes from that of being a knowledge giver to a facilitator of a community in which students engage in reasoning and justification, eventually helping them to adopt these crucial skills.

DISTRIBUTED SCAFFOLDING

With software tools and peer interactions being used as a way to support learning in classrooms, researchers theorize about a *system* of scaffolding that can describe the complex nature of providing support to multiple students in a classroom. Puntambekar and Kolodner (2005) put forth the notion of *distributed scaffolding* to explain

multiple forms of support in the complex environment of a classroom. In this context, support for the design process was provided through the design diaries; in addition, tools such as pin-up sessions and gallery walks were used to help students discuss their designs, providing opportunities for support from teachers and peers. Puntambekar and Kolodner (2005) found that multiple forms of support, distributed across available tools, activities, and agents in the classroom, and integrated in ways that admit redundancy, enhance the learning and performance of a wide variety of students in the classroom. In a complex classroom environment, it can be difficult to align all the affordances in such a way that every student can recognize and take advantage of all of them. When support is distributed, integrated, and multiple, there are more chances for students to notice and take advantages of the affordances of the environment and the activity.

Tabak (2004) presents the notion of *synergistic* scaffolds, as a form of distributed scaffolding. According to Tabak, synergy refers to a pattern of scaffolding in which different kinds of support, such as software and teacher coaching, address the learning need but in different ways. Tabak (2004), states that “synergistic scaffolds are different supports that augment each other; they interact and work in concert to guide a single performance of a task or goal” (p. 318). For example, the software could help students reflect while the teacher might model the necessary strategies, so that the software and teacher support together provides students with a complete set of supports to help them successfully complete the task.

With the development of software tools and classrooms interactions as forms of scaffolds, the notion of scaffolding has evolved since its original conception and has changed considerably from the 1990s into the early 21st century. While later approaches have helped researchers understand the kinds of support that are needed to help classroom communities learn successfully, there have also been some aspects of scaffolding that have been difficult to achieve because of the reality of scaffolding in a classroom. Thus, although the notion of scaffolding has evolved, and understanding of providing support in multiple formats has been enriched, it is necessary to think about the critical elements that are missing, such as the ongoing diagnosis of student learning, the careful calibration of support, and fading, the transfer of responsibility to the student.

Current instantiations of the scaffolding construct have addressed a key aspect of scaffolding, i.e., that scaffolding be based on knowledge of the task and the difficulties that students have. However, the tools are permanent and unchanging; they provide structure and consistency by highlighting the aspects of the tasks that students should focus on. While this is by no means

trivial, support becomes scaffolding only when it is adaptive, based on an ongoing diagnosis of student learning, and helps students to eventually internalize the knowledge and skills when the scaffolds are removed. More research is needed into how a system of scaffolding can be built, so that ongoing diagnosis and fading can be achieved in classroom situations.

SCHOOL BELONGING

The term *school belonging* refers to students' subjective perception of being accepted and respected in their particular school setting. Some researchers have also examined the parallel perception in relation to specific classes; typically using the term *class belonging*. Baumeister and Leary (1995) have proposed that all people have an innate need to belong to social groups and to form positive interpersonal relationships with others. Given the amount of time children and adolescents spend in educational settings and the societal importance attached to school-related activities, students' sense of belonging in those settings is particularly important for their healthy development.

Carol Goodenow (1993) defined students' sense of belonging as the sense of "psychological membership in the school or classroom, that is, the extent to which students feel personally accepted, respected, included, and supported by others in the school environment" (p. 80). Other researchers have studied similar perceptions using terms such as *school connectedness* or *bonding to school*; however, these terms are less common (see Anderman & Freeman, 2004, for a review).

The fact that different researchers have examined similar psychological constructs using different terms can make it difficult to synthesize the findings of studies related to students' sense of belonging. Furthermore, this difficulty extends beyond simply the terminology that is used to include differences in both the psychological theories or models that researchers use and the specific ways in which they measure individuals' perceptions of belonging. Because the sense of belonging or connectedness is a subjective perception, it is best measured using students' self-reports. This is done, most commonly, through the use of questionnaire measures, although interviews with students can also be used (e.g., Kester, 1994). Even within the use of questionnaire measures, however, considerable differences exist in the specific measures available. Perhaps the most widely known measure of school or classroom belonging is the Psychological Sense of School Membership Scale (PSSM; Goodenow & Grady, 1993). This measure includes 18 items and was originally developed for use with students in middle school, focusing on students' sense of being liked, included, and respected in their school. More recently, several researchers have adapted the PSSM to develop shorter versions and for use with college-age students. In contrast to the PSSM, other researchers have used measures that include somewhat broader constructs that include the sense of belonging in conjunction with other perceptions and attitudes (such as valuing academic activities or holding shared group norms). These differences contribute to the sometimes mixed findings from research, which are described in more detail below.

CONSEQUENCES OF FEELING A SENSE OF BELONGING

Researchers interested in students' sense of belonging have examined the perception of subjective membership and acceptance at both the classroom and more general school level, although the latter is more common. Regardless of this distinction, and across a range of grade levels, students' sense of belonging has been associated consistently with a variety of positive academic and affective variables. Furthermore, there is growing evidence that the positive consequences of feeling a sense of

belonging transcend ethnic and cultural differences in students (e.g., Sanchez, Colon, & Esparza, 2005).

In terms of academic variables, one of the most common findings is that students' sense of school belonging is associated with a range of adaptive motivational beliefs. For example, students' sense of belonging in a particular class has been associated with higher expectancies for success in that class; higher perceptions of class tasks as being interesting, important and useful; and intrinsic and mastery goal orientations related to the class. Sense of belonging at the school level has also been associated with more general measures of school-related motivation, self-reported effort, and reduced absenteeism. In contrast to the research on students' academic motivation, the literature is much less clear with regard to associations between students' sense of belonging and their academic achievement. In this area, findings are very mixed. Furthermore, the design of many studies does not allow for clear statements of the direction of effects. That is, although some researchers have reported a positive association between sense of belonging and achievement, it may be that students with a stronger record of prior achievement are more likely to feel as though they are accepted and respected in school, compared to their lower-achieving peers. It is not clear whether promoting a sense of belonging can help a student to achieve at higher levels in the future. Nevertheless, many researchers believe that students' sense of belonging and academic achievement may be reciprocally related over time, with each positive outcome reinforcing the other. Of course, for some students, low levels of perceived belonging and poor academic performance may similarly reinforce one another.

Finn (1989) proposed an Identification-Participation model to describe the process by which some students become alienated from, and eventually drop out of, school. In this model, Finn suggests that a sense of belonging combined with valuing of school-relevant goals (called "identification with school") leads to an increase in the quality, as well as the quantity, of students' participation in school activities. Such increased participation, when met with quality instruction, then leads to successful performances and achievement which, in turn, contribute to a greater sense of identification. In other words, Finn proposes that academic achievement can be both a precursor to and an outcome of the sense of belonging. An important point of Finn's model, however, is recognizing that the sense of belonging is necessary but not sufficient for students' achievement. Simply feeling accepted and respected, without accompanying valuing of school-related goals and appropriate instruction, will not lead to successful performance on academic tasks.

In addition to academic outcomes, researchers also have investigated associations between students' sense of

belonging and a range of affective and well-being related outcomes. One highly influential study published by Resnick and his colleagues (1997) reported that the sense of school connectedness (another term for school belonging) was associated with lower levels of emotional distress, lower suicidal ideation, lower levels of involvement in violence, and less frequent use of tobacco, alcohol, and marijuana in adolescents. Subsequently, other researchers have found perceived school belonging to be associated with lower levels of depression and general negative school-related affect, along with avoidance of behavioral problems in school. In addition, belonging is associated with increased positive school-related affect, empathy, self-esteem, and higher levels of general optimism (E. Anderman, 2002; L. Anderman, 1999; Battistich, Solomon, Kim, Watson, & Schaps, 1995).

FACTORS THAT CONTRIBUTE TO THE SENSE OF BELONGING

Given the range of positive academic and affective outcomes associated with students' sense of belonging, it is important to understand those factors that support this perception. Unfortunately, the research in this area is less extensive than that described in the previous section (see Anderman & Freeman, 2004, for a review of this research). Some researchers have reported differences in the sense of belonging in terms of characteristics of the students themselves. For example, there is some evidence that, among adolescents, girls tend to report higher levels of school belonging than do boys. Similarly, as noted earlier, adolescents with lower levels of academic achievement may be less likely to report a sense of belonging than their higher-achieving peers.

Some researchers have also reported differences in reported school belonging related to students' ethnicity; however, the findings in this regard are quite mixed. Although some data suggest that minority students feel less sense of belonging in their schools than do White students, it may be that students' representation within the school population is a critical factor. That is, when African American or Hispanic students make up the majority of a school's population, and particularly when the teaching faculty is ethnically mixed, those minority students have been found to report higher levels of belonging than their White classmates. In other words, minority status in relation to the population of the school, rather than in the more usual sense of the term, may be the more important determinant of students' sense of belonging. Finally, in terms of individual characteristics, students' beliefs about the academic work presented in their classes and their self-concepts also are related to their sense of belonging. A strong global self-concept and high perceived task values (that is, the perception that tasks are interesting, important, and useful;

see Eccles & Wigfield, 1995) are strongly associated with higher levels of belonging.

Beyond individual and group differences in students' sense of belonging, there also is evidence that several characteristics of schools and classrooms themselves can help to foster the sense of belonging for all students. There is clear evidence that average levels of students' sense of belonging vary significantly across schools and classrooms (see Anderman & Freeman, 2004, for a review). Interestingly, these differences do not appear to be systematically related to school or class size, or school type (e.g., public, private, or parochial). In contrast, there is some evidence that students may report higher levels of belonging in rural schools compared to urban schools, and in K-8 or K-12 structured schools compared to traditional middle and high school structures. Finally, average levels of school belonging in adolescents may tend to be higher in schools in which larger numbers of students participate in extra-curricular activities.

Beyond characteristics of the school in general, the instructional and interpersonal characteristics of specific classes also contribute to students' perceptions of belonging at both the class and general school level. In fact, these more proximal influences may be more important in shaping students' day-to-day experiences than are school-level factors. Furthermore, the variables that have been associated with higher levels of belonging are quite consistent across students of different ages, ranging from elementary school to undergraduate students in college.

Battistich, Solomon and their colleagues conducted a long-term intervention in elementary schools, known as the Child Development Project (CDP), aimed at creating a greater sense of community in students. In this work, a sense of community included students' sense of belonging, along with the development of shared values and having a role in decision-making. Schools in the CDP program adopted a range of policies and practices, including the use of cooperative learning activities, developmental discipline strategies, emphasizing interpersonal helping and prosocial behavior, and promoting non-exclusionary attitudes in their students. Direct observation of teachers' classroom behaviors demonstrated that warmth and supportiveness, emphasis on prosocial values, encouragement of cooperation, and elicitation of student thinking all were associated with an increased sense of community among students.

Research conducted in middle-school settings also supports the importance of a classroom social environment characterized by mutual interpersonal respect. L. Anderman (2003) examined change in middle school students' sense of belonging over time and found that, in spite of an overall decline in belonging between sixth and seventh grades, this decline was partially corrected when students

perceived their teachers as requiring students to treat one another respectfully. In addition, that study showed strong support for the importance of a classroom context that focused on individual mastery and learning as the purpose for academic tasks (that is, a mastery goal focus, Ames, 1992). Across the sixth and seventh grades, a perceived focus on meaning and understanding in academic tasks was the single strongest predictor of students' sense of belonging in school, even after other characteristics were taken into account. Finally, preliminary research conducted in college classrooms suggests that very similar characteristics may help promote a sense of class belonging for undergraduate students. Not only is a sense of belonging still important for students at the college level, but their sense of belonging is higher in classes where instructors encourage student participation, are perceived as warm, friendly, and helpful, and as being well organized and prepared for classes (Freeman, Anderman, & Jensen, 2007). Less research has been conducted on promoting a sense of belonging in high schools. This remains an important area to be developed.

IMPLICATIONS FOR TEACHERS

As described in the preceding section, empirical research has demonstrated the importance of a number of school- and classroom-level policies and practices for fostering and maintaining students' subjective sense of belonging. What is particularly notable about these findings is, first, the remarkable consistency in findings across widely varying age groups and, second, that many of the characteristics identified are able to be modified. In other words, students' sense of belonging seems to be shaped less by fixed and objective characteristics of their schooling (such as school size) and more by those attitudes and practices that are within educators' power to control.

Perhaps the first and most important implication of this body of research for teachers is that they need to recognize the value of students' sense of belonging, both in their classes and in the school as a whole. Being aware of students' subjective sense of acceptance, respect and inclusion, as distinct from their objective membership of the school community, may be an important first step in sustaining students' academic and affective development and well-being. Beyond this initial awareness, the research literature also points to a number of specific characteristics of classes that are likely to foster students' sense of belonging at all levels.

In terms of instructional practices and pedagogy, teachers who encourage high levels of student participation in activities, particularly those who ensure equal participation from all students, are likely to foster a sense of class belonging. Importantly, this benefit is most likely to occur when participation is designed as cooperative

and focused on the individual pursuit of understanding and mastery, rather than as demonstrating one's knowledge before classmates or competing. Students' sense of belonging can also be fostered through participation in decision-making within class, such as helping to develop class rules for behavior, or having some limited choices in terms of academic tasks. Teachers who are perceived as committed to their students' learning, holding high expectations for student success and providing assistance when it is needed, also are likely to promote a sense of belonging. Beyond the strictly pedagogical aspects of classes, the interpersonal and affective tone of classes also will support students' sense of belonging. Teachers need to communicate their own warmth and availability to students but they also play a critical role in setting the climate for interactions among students in class. Teachers can communicate the importance of prosocial and cooperative attitudes, active participation and mutual respect among class participants. Taken together, this research suggests that teachers will be most likely to promote and maintain students' sense of belonging when they are able to balance a strong focus on students' learning and academic progress with a climate of warm and supportive interpersonal relationships in class.

SCHOOL CLIMATE

Definitions of school climate include a critical core set of common elements. The definition of school climate usually encompasses dimensions of the perceived social environment that: (a) have a contextual influence on the learning and development of students, (b) remain stable over time, and (c) can be meaningfully aggregated across raters. Definitions of climate characteristically focus on conditions as they are perceived by students, teachers, or other participants in a school setting, rather than on objective aspects of the setting. Illustratively, school climate may be reflected in the frequency with which teachers go out of their way to explain material to students, a behavior that can be observed by students. However, objective characteristics of the school, such as the percentage of teachers who are certified in the area that they teach, would not fall within the scope of climate assessment. School climate has been conceived as a set of conditions that influence student outcomes, in part by establishing norms and expectations for behavior. Climate dimensions mediate the effects of educational interventions on student outcomes, rather than being the final outcomes themselves. For example, the amount of emphasis that is placed on learning is a common focus of climate assessment, while students' grade point averages would be viewed as an outcome indicator.

Climate assessments are thought to have a contextual effect in the sense that school-level differences in climate dimensions are thought to be associated with differences between schools in student outcomes in ways that are not accounted for by individual differences in students' background characteristics and prior achievement. Climate dimensions are thought to be stable across time, absent any systematic effort to change them. For example, climate scores in middle schools remain stable over 2 years, even when the student membership of the building turns over (Brand, Felner, Shim, Seitsinger, & Dumas, 2003), suggesting that climate persists over time independent of

the individuals who comprise the membership of a building. Finally, while students may offer diverse opinions about the climate of their school building, their ratings can be meaningfully and reliably aggregated to create school-level scores (Brand et al., 2008; Griffith, 2000).

Research on school climate has focused on the proximal conditions affecting students' learning, focusing on students' and teachers' experiences of the school as a learning environment. A related body of work on the organizational climate of the school also considers teachers' experiences of the school as a workplace (Halpin & Croft, 1963; Hoy & Tarter, 1997; Kelly et al., 1986; Rentoul & Fraser, 1983). Illustratively, the educational climate literature considers such dimensions as teacher support or achievement emphasis, while the organizational climate literature considers teachers' experiences of participation in decision-making at work. The present review focuses on the educational climate of the school, although the influence of organizational climate variables on students' learning and adjustment must also be acknowledged.

Implicitly, many educators and researchers think of school climate as being one-dimensional, in the sense that climate is generally positive or negative. Another form of one-dimensional thinking associates the entire domain of school climate with a specific dimension. In this vein, the domain of climate is equated with just teacher support, personalization, sense of community, relationships, achievement emphasis, or school safety. While each of these may be important aspects of school climate, no single dimension encompasses the entire domain of school climate. Rather, numerous studies suggest that a comprehensive assessment of school climate should encompass multiple dimensions.

An early, and very influential, conceptual framework was proposed by Trickett and Moos (1973), who suggested that classroom climate assessment should address three overarching conceptual dimensions: Relationships, Personal Growth or Goal Orientation, and System Maintenance and Change. This conception of climate dimensions has broadened the perspective of investigators on the multidimensional nature of climate, and has led to efforts to empirically differentiate underlying dimensions of climate through factor analysis. Illustratively, Brand and his colleagues (2003) report that students' ratings of the ten ISC-S scales reflect the following higher-order dimensions: Developmental Sensitivity, Pro-social Emphasis, Contextual Negativity, and Safety Problems. Cumulatively, these perspectives suggest that efforts to improve school climate need to be cognizant of how school conditions vary on multiple dimensions.

ASSESSMENT OF CLASSROOM AND SCHOOL CLIMATE

School and classroom climate dimensions have been assessed through structured inventories that ask participants to indicate the extent to which they agree or disagree with specific statements about the social environment. Scale scores are computed by summing or averaging responses to the items that comprise a dimension. Pioneering work on the development of structured climate inventories was undertaken during the 1960s by Herbert Walberg and colleagues (Walberg & Anderson, 1968) and George Stern (1970). During the 1970s Walberg's work led to the development of the Learning Environment Inventory (LEI) (Fraser, Anderson, & Walberg, 1982) for secondary level classrooms, and the My Class Inventory (MCI) (Fraser et al., 1982), for elementary classrooms. During the same period, Edison Trickett and Rudy Moos published the Classroom Environment Scale (CES) (Trickett & Moos, 1973; Moos, 1979). Though the CES was initially developed for use in secondary level classrooms, this instrument was adapted to assess school-level climate in high schools (Felner, Aber, Cauce, & Primavera, 1985), and classroom climate in the early elementary grades (Toro et al., 1985). Research using the LEI and CES proved to be critical in establishing the importance of climate assessment for research and intervention.

Investigations of climate have often focused on the social climate of classrooms, even in secondary level schools where students occupy multiple classes throughout the school day. The classroom-level focus reflects the interest of investigators in changing instructional practices and conditions in particular subject-specific classrooms. Over the past two decades, increased attention has been given to the assessment of whole school climate, reflecting growing interest in implementing and evaluating the effects of comprehensive school reform models. The emphasis on school-level climate is reflected in the work of James Comer's School Development Program on the School Climate Scale (Haynes, Emmons, & Comer, 1993), as well as climate studies by Shaps (Battisch, Solomon, Kim, Watson, & Shaps, 1995) and Raudenbush (Raudenbush, Rowan, & Kang, 1991), and the Project on High Performance Learning Communities (HiPlaces) (Felner, Seitsinger, Brand, Burns, & Bolton, 2008). As part of the HiPlaces project the Inventory of School Climate (ISC) (Brand, Felner, Shim, Seitsinger, & Dumas, 2003) has been administered in more than 3,000 whole-school assessments in the past two decades. This instrument has also been widely adopted in other projects in the United States and internationally. The ISC assesses the perceived social environment of middle level and secondary schools, and is also available in a form that is appropriate for elementary school children.

In addition, the teacher version of the ISC has been found to predict students' climate ratings and outcomes (Brand, Felner, Seitsinger, Burns, & Bolton, 2008). Drawing upon the work of the authors cited above, and factor analytic research in large and diverse samples, the ISC assesses ten dimensions of school climate, including teacher support, consistency and clarity of rules and expectations, student commitment to achievement, negative peer interactions, positive peer interactions, disciplinary harshness, student input in decision-making, instructional innovation and relevance, support for cultural pluralism, and safety problems. Each of these dimensions of perceived school climate has been found to be associated with multiple indices of students' learning and adjustment, as is shown in the following section.

SIGNIFICANCE OF SCHOOL CLIMATE FOR STUDENTS' LEARNING AND DEVELOPMENT

School climate has been found to be associated with multiple areas of students' learning and development. A pervasive pattern of relationships has been found between climate dimensions and students' academic, behavioral, and socioemotional adjustment, even after partialling out the effects of poverty on student outcomes. The relationship of climate to each of these adjustment domains are considered in turn, focusing on findings from large-scale studies of young adolescents (Brand et al., 2003). The dimensions of school climate discussed below have also been found to be associated with student learning and adjustment in large scale samples of students at the elementary and high school levels (Brand, Felner, Seitsinger, & Hupkau, 2006).

To assess the impact of climate on students' learning, it is critically important to examine variation in students' academic motivation, as well as in their scores on standardized achievement tests. Academic motivation merits attention because students' aspirations, expectations, and sense of self-efficacy influence their long-term adaptation to school as well as decisions about the pursuit of advanced training and education. In schools with higher levels of student commitment to achievement, students attain higher scores on standardized tests of reading and math. In addition, multiple dimensions have been found to be associated with students' academic motivation. Higher teacher expectations, academic aspirations, and academic efficacy have been found in schools with higher school mean levels of teacher support, structure, positive peer interactions, and instructional innovation. In schools that students rated as having fewer safety problems, students reported higher self and teacher expectations, academic aspirations, and efficacy. Better grades and teacher expectations were associated with higher

mean levels of student participation in decision-making, and lower levels of disciplinary harshness and negative peer interactions, while higher student self-expectations and academic aspirations were related consistently with higher mean levels of support for cultural pluralism.

Turning to indicators of students' behavioral adjustment, higher levels of smoking, drinking and drug use, and more favorable attitudes toward these activities, were found in schools that students rated as lower in teacher support, student commitment to achievement, and instructional innovation, and higher in safety problems. Higher levels of delinquency and teacher-rated aggression were found in schools that students rated as having higher levels of negative peer interactions, disciplinary harshness, and safety problems. Higher levels of delinquency and classroom aggression were also found in schools that students rated as having lower levels of teacher support, student commitment to achievement, structure, and positive peer interactions. Turning to indices of socioemotional adjustment, higher levels of peer self-esteem, and lower levels of depression, have been found in schools in which students report higher levels of teacher support, structure, student commitment to achievement, positive peer interactions, and instructional innovation, as well as lower levels of safety problems. In addition to the climate dimensions noted above, support for cultural pluralism appears to be particularly important for academic performance, aspirations, and self-expectations among minority students (Brand, Felner, Seitsinger, Burns, & Jung, 2007). Support for pluralism also moderates the impact of poverty on students' academic performance and motivation. Gaps between students from low-income families and those from more affluent families are significantly smaller in schools that have higher levels of support for cultural pluralism.

While the majority of studies on school climate have been cross-sectional in nature, initial studies have examined the longitudinal impact of climate dimensions on trajectories of adjustment, particularly in early adolescence (e.g., Brand et al., 2007; Kuperminc, Leadbeater, & Blatt, 2001; Loukas & Murphy, 2007). Teacher expectations often decline during the middle school years. However, these declines were not evident in schools that were characterized by higher levels of structure, student commitment to achievement, positive peer interaction, and instructional innovation, as well as lower levels of disciplinary harshness. Gains over time in students' self-expectations and sense of efficacy were associated with higher levels of student commitment to achievement, positive peer interaction, and instructional innovation (Brand et al., 2007). School climate dimensions are associated with differential rates of onset for smoking, drinking, and drug use during early adolescence (Brand, Felner, Seitsinger, Shim, & Hupkau, 2005). Students who did not

smoke, drink or use drugs in sixth grade were less likely to initiate these behaviors by eighth grade in schools that had higher levels of teacher support, student commitment to achievement, student involvement in decision-making, and instructional innovation and relevance, as well as lower levels of disciplinary harshness, negative peer interactions, and safety problems. Cumulatively, findings from the cross-sectional and longitudinal studies again emphasize the importance of a comprehensive, multi-dimensional perspective on school climate.

CURRENT ISSUES IN THE CONCEPTION AND MEASUREMENT OF SCHOOL CLIMATE

The metaphor of “climate” has often, unintentionally, suggested that the perceived social environment of the school is like the weather: critically important, but difficult to control. This view of school climate can, implicitly, lead to the assumption that climate is simply a given, or the product of complex forces that cannot be systematically and deliberately addressed by educators. However, the findings of numerous studies suggest that school climate can be enhanced by systematic changes in the social organization and instructional regularities of the school (e.g., Maehr & Midgley, 1996). Numerous dimensions of school climate are associated with differences in the size, structure, and activities of interdisciplinary teams in middle grade schools (Brand et al., 2007). Other factors affecting school climate include classroom instructional practices, teacher attitudes toward the implementation of research-based practices, teacher readiness and professional development, and teacher role strain and job satisfaction. Change in school climate can result from systematic changes in school organization, instruction, and other regularities of the school. Indeed, the effects of structural and organizational changes on students’ learning may be mediated by dimensions of school climate.

STUDENT PERCEPTIONS OF SCHOOL CLIMATE

Initially, theories of social climate (e.g., Moos, 1979) proposed that social climate reflected consensual perceptions of the social environment of the school that were shared by occupants of the classroom or school building. However, since the late 1990s, numerous studies have shown that ratings of social climate vary much more within school buildings than they do between school buildings. Illustratively, Griffith (2000) reports that only 3% to 6% of the variance in school climate ratings is accounted for by differences between school buildings. Such findings suggest that the average rating of climate in a school does not necessarily reflect the perceptions that are shared by all students. However, even though a

school-level mean score on a climate scale may not reflect a consensus of opinion among students about their building, variation in this score account for a substantial portion of the variance between buildings in indices of students’ learning and adjustment (Brand et al., 2003). Further, school mean scores also tend to be highly correlated when they are drawn from randomly selected subsamples of students from the same building (Brand et al., 2003; Griffith, 2000). Obtaining a consensus of opinion across students might not be a necessary condition for obtaining a reliable and predictive assessment of school climate dimension.

ANALYSIS OF MULTI LEVEL DATA FROM STUDENTS, CLASSROOMS, AND SCHOOLS

Efforts to assess the school-level impact of climate dimensions have been greatly enhanced by advances in the field of Hierarchical Linear Modeling (HLM) (Raudenbush, Rowan, & Kang, 1991). HLM is a statistical technique that has been developed specifically for analysis of multi-level, hierarchical data. Initial efforts to relate climate with adjustment examined correlations at the level of the individual student (which looks at a conceptually quite different level of analysis), or else carried out correlational analyses of the relationship between school mean scores on climate and adjustment (which tends to overestimate school-level effects). HLM has enabled investigators to make more accurate estimates of school-level effects of climate on students’ developmental trajectories, and to better understand how school-level climate can moderate the effects of students’ background characteristics on learning and school adaptation.

ALTERNATIVE METHODS OF ASSESSING CLIMATE

While standard methods for assessing school climate rely on the collection of data from students, circumstances can arise in which reliable survey data from a representative sample of students is not available. In such circumstances, investigators may need to rely on alternate sources of information to assess climate dimensions. Illustratively, Pianta and colleagues (Pianta et al., 2002) have developed an observational system to assess climate conditions, as well as instructional and organizational regularities, in kindergarten classrooms. This approach is particularly critical for the investigation of climate among children who are too young to complete climate inventories. In addition to using observational data, investigators may turn to teacher ratings to assess climate when representative and reliable student data are not available. However, caution should be exercised when using teacher ratings as a proxy for student ratings. It

may be particularly important to choose a teacher instrument that has been validated for the purpose of predicting students' ratings and outcomes (Brand, et al., 2008).

OVERVIEW

School transitions mark the time period when students move from one school environment into another. Transitions occur at a variety of ages and vary greatly across school districts. Students often experience problems adjusting to changes in educational environments; consequently, teachers need to receive professional development training to assist students in making successful school transitions.

MAJOR TRANSITIONS

Although transitions can occur at many different time periods, several periods are typical. The transition into kindergarten is the first major school transition; however, for some children, who already have attended childcare or preschool, the transition into kindergarten may be much easier than for other children, who have stayed at home until just prior to kindergarten. Data from the National Center for Education Statistics indicate that most children

Mortarboards against the sky signal school transitions. CHRIS CHEADLE /ALL CANADA PHOTOS/GETTY IMAGES.

do experience at least some care before kindergarten from non-parental caretakers; for example, in 2001, only 26.1% of preschool children were cared for solely by parents (U.S. Department of Education National Center for Education Statistics, 2006). Consequently, for most children, the transition into kindergarten is not the first time they have been out of the home.

The second major transition for most students is the transition from elementary school into middle or junior high school. Much research has been conducted examining the effects of this transition on a variety of outcomes. Research generally indicates that the transition into middle school often is problematic for early adolescents because the instructional practices of many middle schools do not meet the developmental needs of early adolescents (e.g., Anderman & Maehr, 1994; Eccles & Midgley, 1989; Simmons & Blyth, 1987). Many students become less motivated and begin to lose interest in school after this transition.

The third transition often is the transition from middle or junior high school into high school. There is less research on this transition than on some of the other school transitions. Nevertheless, a growing body of evidence suggests that this transition often is traumatic and problematic for some students (Eccles, 2008).

For some students, high school represents the final stage of formal education. However, for many students, the transition from high school into college represents another very important school transition. Some students attend two-year community colleges, whereas others attend four-year colleges or universities. The transition into college for many students represents the first time that the student attends school while simultaneously living away from home. Many students do not adapt well to college life and experience academic difficulties during their first year of school, which can eventually lead to dropping out (Tinto, 2006).

EFFECTS OF SCHOOL TRANSITIONS

Transitions are extremely important because they represent major shifts in the daily contexts in which children and adolescents interact. For some students, the transition is smooth and peaceful, whereas for others it is stressful.

School transitions are related to a variety of behavioral and psychological changes. Research indicates that across transitions, students often experience changes in relationships with peers, parents, and teachers. In addition, behavioral problems often become evident after a school transition, which is particularly true when students interact with new peer groups after the transition. Much research has examined changes in academic variables after transitions; many transitions are related to

notable changes in students' motivation to learn, academic performance, and attitudes toward school.

IMPLICATIONS FOR EDUCATORS

It is very important for educators to be well prepared to assist students during transitional periods. Teachers cannot assume that students will naturally adjust to new learning environments with little difficulty. Educators must attend to the developmental needs of children and work collaboratively with parents, school counselors, and administrators to ease transitions for students of all ages. Programmatic efforts to facilitate such transitions are growing in number.

ELEMENTARY SCHOOL

Kindergarten marks the entrance to formal schooling and is an important time of transition for children and families (Pianta, Rimm-Kaufman, & Cox, 1999). Children are changing developmentally in ways that potentially support adaptation to the expectations and demands of the kindergarten setting. Given the number of changes that characterize the transition period, identification of factors that support successful transition are critical. This entry describes the changes children experience as they transition to kindergarten and discusses factors related to successful adjustment to schooling.

TRANSITION TO KINDERGARTEN

Contextual changes from preschool to kindergarten coincide with developmental changes. As children physically mature, their experiences change, providing additional opportunities for skill development in a repeating and reciprocal cycle. Through the preschool years, basic skills increase rapidly. Greater motor coordination allows children to engage in more physical activity (e.g., running, climbing) essential for interactive play and group games that become more prominent in kindergarten. Changes in fine motor skills allow children to participate in academic tasks (e.g., writing, using scissors) and support adaptive skills (e.g., dressing, tying shoes) that promote independence. Language and communication skills become more sophisticated and refined, allowing greater expression and understanding of ideas, feelings, and knowledge. These basic developmental changes that are readily observed are accompanied by changes in cognition and psychosocial development that are explained by theoretical perspectives.

Jean Piaget (1896-1980) developed a theory of cognitive development that placed children of transition age near the end of the preoperational period, moving toward the concrete operational period. This movement is characterized by decreasing egocentrism and increasing flexibility in thinking, leading to increased perspective taking, understanding of functions and relations, cause and effect, and simultaneous consideration of features of objects (e.g., length and width). From an information-processing perspective, changes in cognition are accompanied by increases in learning and memory capacity that result in diversified strategies for learning (Miller, 2002). As cognitive capabilities change, children interact with and store knowledge in a way that increases capacity for learning and connecting new information to existing information. These cognitive advances contribute to effective problem-solving in an academic sense and in interpersonal interactions. Flexibility in thinking, greater memory capacity, and more effective problem-solving can support focused attention, task persistence, and increased motivation to learn. Increased perspective taking can facilitate social problem-solving, the development of empathy, self-regulation and self-control, necessary skills for school success.

Developmental changes are also reflected in theories of social development. According to the psychosocial perspective of Erik Erikson (1902-1994), as an individual develops, new skills create opportunities and demands. Physical and cognitive changes contribute to increasing autonomy and a developing sense of self through participation in new experiences. Adaptation to the opportunities and challenges in school is an important element of Erikson's theory of identity development, which places children of transition age in the stage of

Industry vs. Inferiority, characterized by the sentiment “I am what I learn.” Further, emotional and moral development reflects a shift toward social comparisons and an internalized sense of standards, rules and values based on fairness and equality. Success in school, academically and interpersonally, provides children with a sense of mastery and competence that supports continued development.

Sociocultural theory provides a larger context in which to consider the cognitive and psychosocial changes that children experience during transition. Social interaction is critical to development, and the nature of interaction shifts to accommodate and challenge the growing child. As children mature, their participation in sociocultural activities and interactions with others changes, affording greater opportunities for development as evident in the different experiences from preschool to kindergarten. Key to this process is the notion of the zone of proximal development, developed by Lev Vygotsky (1896–1934), which can be defined as the difference between what a child can do independently and what the child can do with adult support. Successful learning within the zone in academic or social domains is characterized by shared goals, scaffolding, and social interactions between a child and a more competent individual. Thus, teachers, caregivers, and competent peers play a significant role in supporting adjustment to formal schooling.

In sum, developmental changes that characterize the age of transition to formal schooling prepare children to become more active learners and more social beings during a time of increased demands for social competence, both of a learning-related and peer-related nature. In kindergarten children enter a world of opportunities and challenges different from their preschool or home environments, and their experiences in that context set the stage for continued development.

CONTEXTUAL CHANGES IN TRANSITION TO KINDERGARTEN

Preschool and kindergarten settings vary a great deal in curricular content, structure, and focus. In general, preschool settings tend to be characterized by an approach to education that emphasizes child-directed learning through play, whereas kindergarten settings are more likely to emphasize the acquisition of skills and knowledge through direct instruction approaches and structured activities (Hemmeter, 2000). From a sociopolitical context several factors may contribute to observed differences in the two settings. Preschool programs have historically operated independently from the formal schooling system, and evaluation outcomes in preschool have been more likely to focus on health and safety than on early academic performance or development of social competence. Coupled with a significant emphasis on child-directed learning and play,

this has resulted in few formal instructional curricula for preschoolers. In contrast, physically located in schools and conceptually linked to formal schooling, kindergartens may experience accountability demands, attention to performance and standards, and emphasis on foundational academic skills. As such, formal curricula for kindergarten are widely available and used in schools with an eye toward academic outcomes (e.g., learning to read) that change the nature of children’s experiences.

Changing experiences are accompanied by changing expectations related to learning and social interaction. As time on learning increases, classroom daily activities shift from more play-based in preschool to more structured and academically focused in kindergarten. Further, because more children are enrolled in kindergarten classrooms than in preschool classrooms, children may be interacting with a larger and more heterogeneous group of children in the context of higher child-teacher ratios. Learning-related social skills (McClelland & Morrison, 2003) that enable children to attend to instruction, follow directions, participate in group activities, organize materials, and persist in challenging tasks become more important. In addition, membership in group and individual relationships (Schwartz, Garfinkle, & Davis, 2000) becomes increasingly complex to negotiate and requires effective peer-related and adult-related social skills, such as initiating and maintaining positive interactions, sharing, turn-taking (McClelland & Morrison, 2003), effective social communication, and regulation of emotions (Izard, Trentacosta, King, & Mostow, 2004). Behaviors that may be tolerated in preschool settings and viewed as within the range of developmentally appropriate may be considered inappropriate and problematic in terms of school adjustment. For example, difficulty following directions, sharing, compliance, or lack of social interaction is likely to generate more concern in kindergarten settings. As such, it is important to understand expectations of kindergarten settings to facilitate transition.

FACTORS THAT CONTRIBUTE TO SUCCESSFUL TRANSITION

Research suggests that academic development at kindergarten entry has both direct and indirect effects on first grade schooling outcomes, and the link between early performance and later achievement has been demonstrated through grade 10 (Stevenson & Newman, 1986). Thus, upon entrance to kindergarten children need to have foundational skills to support continued development. Critical early literacy skills in language development, phonological awareness, letter-sound correspondence, concepts about print, and alphabetic principles need to be in place for a child to be prepared to read and write (Snow, Burns, & Griffin, 1998). Children’s language structures and word

knowledge continues to grow, facilitating development of more complex phonological neighborhoods that support early literacy skills such as rhyming (Snow et al., 1998). Similarly, children's early informal numerical understanding provides a structure for formal instruction in skills and concepts that expand their ability to use mathematics in abstract ways (Bowman, Donovan, & Burns, 2001). Facility with a mental number line constitutes an important conceptual framework for mathematical learning (Griffin & Case, 1997). Without foundational skills in key academic areas, the gap between children with skills and those without is likely to continue to grow throughout kindergarten and subsequent grades (Bowman et al., 2001).

Although necessary, early academic skills alone are not sufficient for successful transition to elementary. The degree to which children successfully navigate the kindergarten social environment in terms of classroom rules and expectations (learning-related social skills), peer relationships (peer-related social skills), and adult relationships (adult-related social skills), can dramatically affect short-term and long-term adjustment to kindergarten and to school in general.

Acquisition of *learning-related social skills* such as task completion, listening, following directions, active participation, attentiveness, compliance, self-regulation, and independence are necessary for kindergarten success as they facilitate the ability to attend to, participate in, and benefit from instruction (McClelland & Morrison, 2003). Kindergarten children rated by their teachers as having high levels of learning-related social skills have significantly less risk for being identified with behavior problems (Cooper & Farran, 1988). Kindergarten teachers have also specified that key behaviors such as listening to the teacher and complying with teacher directions are critical to successful adjustment to kindergarten (Pianta et al., 1999). Moreover, in a survey of 3,500 kindergarten teachers across the United States, 46% indicated their biggest concern was that entering children "had difficulty following directions" (Rimm-Kaufman, Pianta, & Cox, 2000). Studies have shown connections between learning-related skills at the beginning of kindergarten and later academic success, with learning-related skills accounting for unique variance in children's reading, mathematics, vocabulary, general information and alphabet skills in kindergarten and through the end of second grade (McClelland & Morrison, 2003).

Acquisition of *peer-related social skills* such as the ability to initiate and maintain interactions, share, cooperate, and demonstrate respect for other children (McClelland & Morrison, 2003) significantly affect a child's transition to school and subsequent adjustment (Ladd & Coleman, 1997), and is commonly reflected in the number of mutual friendships that children have, peer social

status, and general climate of peer interactions (Phillipsen, Deptula, & Cohen, 1999). Research suggests that children who engage in high rates of positive initiations toward peers receive high rates of positive initiations from peers (McConnell et al., 1984), and that children tend to maintain similar relationship patterns across kindergarten (Ladd & Coleman, 1997). Children who maintain friendships during the first two months of kindergarten are more likely to view school favorably (Ladd & Coleman, 1997) and children with high levels of prosocial skills tend to have more mutual friendships (Ladd, Birch, & Buhs, 1999). In addition, children who engage in positive peer interactions demonstrate more positive overall engagement in the classroom (Fantuzzo, Bulotsky-Shearer, Fusco, & McWayne, 2005), suggesting a relation between learning-related and peer-related social skills.

Adult-related social skills have an important role in the transition to elementary because children transitioning to kindergarten are still quite young, and have largely relied on adult modeling and nurturance from birth. Because parents and caregivers are the first socialization agents of young children, their influence has lasting effects on their child's social development. Children who report closeness with their parents tend to adjust best to school with more friends, fewer conflicts, and higher levels of peer acceptance, with teachers reporting frequent on-task behavior, following directions, and overall classroom competency (Clark & Ladd, 2000). This is important because children tend to develop relationships with teachers that mirror their relationships with parents, that is, if a child is clingy and needy or distant with a parent, they are likely to interact similarly with a teacher (Clark & Ladd, 2000). Children with appropriate teacher relationships are more likely to have important social skills, including self regulation and independent work habits (Pianta, Nimetz, & Bennett, 1997) as well as higher academic achievement, more mutual friends, and a higher level of peer acceptance (DeMulder, Denham, Schmidt, & Mitchell, 2000). Some research has suggested that parent involvement in school activities starting at kindergarten strongly impacts a child's adjustment to school, which can maintain through at least sixth grade (Pettit, Bates, & Dodge, 1997).

In conclusion, the transition to kindergarten is marked by important changes. Children are changing developmentally in ways that can support their adjustment and growth cognitively and socially when fostered in sensitive interactions with others. Further, the context of learning and social interaction changes as children move from preschool and home settings to formal school environments, resulting in new opportunities and challenges for skill development. With changes in context, typically there are changes in expectations for early academic performance and social behavior that require a

solid foundation as well as continued development of skills and knowledge (Pianta et al., 1999). School success is largely determined by competence in the areas of academic skills and relationships with peers and adults. Key elements from these areas have collective and significant influence on a child's transition to elementary school and subsequent school adjustment (Pianta et al., 1999). Viewed together, a detailed picture emerges of the skills and experiences most likely to lead to successful transition to elementary, providing direction for early education and kindergarten settings in their efforts to support young children's development.

MIDDLE SCHOOL

Most educational systems in the United States involve students attending a middle school (traditionally called junior high school) for two to three years, sandwiched between the elementary and high school grades. There is considerable variability in the grades included in middle schools, although sixth through eighth are the most common. Grade configuration is influenced primarily by social, demographic, and space considerations within school districts. Middle schools span elementary schools' focus on providing all students with a breadth of educational experiences and developing core knowledge and skills, and high schools' educational specialization that prepares students for the workforce or post-secondary education. They typically offer new subjects that students can elect to study, different levels of a subject within the same grade, and teachers with subject-specific specialization for academic subjects (resulting in students being taught by multiple teachers).

The transition to middle school coincides with early adolescence the developmental transition period between childhood and adulthood. Developmental

changes associated with adolescence have bearing on all students' experiences.

DEVELOPMENTAL CHANGES COINCIDING WITH THE TRANSITION TO MIDDLE SCHOOL

The early adolescent period is a time of dramatic physical, cognitive, social, and psychological growth and development. Not only must adolescents adjust to their own changes, they must also adjust to others treating them differently because of that development.

Physical Development. The onset of puberty usually marks the beginning of adolescence. Females begin puberty approximately eighteen months earlier, on average, than males; however, timing varies widely. Adolescents experience a dramatic growth spurt, with significant gains in height and weight, development of secondary sexual characteristics, and changes in fat and muscle distribution. Sexual interest also develops. Adolescents often appear awkward with their bodies, because of their rapid and irregular growth. Pubertal timing, relative to peers, is related to adolescents' body image and satisfaction with their appearance; late-developing females and early-developing males hold the most positive perceptions.

Cognitive Development. Adolescence is characterized by steady improvement in a range of cognitive abilities, both because of biological maturing and experiences. Adolescents process information faster and more efficiently, and their memory is better than in childhood. They become more meta-cognitive, or able to think about their thoughts and actions. However, they also tend to overestimate their abilities and underestimate their vulnerabilities. Adolescents become increasingly able to engage in complex and abstract thinking, reasoning, decision making, and problem solving. With their improved cognitive abilities they appreciate others' perspectives better, reflect on themselves more, and become more self-aware. With these changes come greater self-consciousness and a tendency to believe that their experiences and feelings are unique to themselves. Finally, adolescents become better at regulating and coordinating their thinking, emotions, and behavior.

Social Relationships. Another dramatic change associated with adolescence is the increased importance of peer relationships. Young adolescents spend more time with peers, and friendships become more intense, close, and involve more self-disclosure. Distinct peer groups, with different characteristics, reputations, and status hierarchies, appear during early adolescence. With this emergence of cliques and crowds comes concern about social image. The desire to fit in and be like others is also strongest in early adolescence. This desire for acceptance

is accompanied by greater use of strategies designed to project a particular image.

Psychological Development. With the development of adult-like characteristics comes a desire for greater independence and autonomy. Changes in young adolescents' physical characteristics, cognitive abilities, and social relationships influence their identity development—perceptions of who they are, what they are good or not good at, what they value or devalue, and what they aspire to or fear becoming. Establishing an identity involves the process of exploring and embarking on commitments (both emotionally, and with time and resources) to particular paths and outcomes. Although identity continues to develop through adulthood, it is especially important during adolescence; choices made at this time can have far-reaching consequences for education, employment, and relationships.

CHANGES WHEN STUDENTS MOVE TO MIDDLE SCHOOL

Middle schools typically afford experiences quite different from those students were accustomed to. The school buildings tend to be larger, serving students from multiple elementary schools, and employ subject-specific specialist teachers. Students also experience changes in what and how they are taught, how they are evaluated, their interactions with teachers and peers, and institutional norms and requirements. The nature of these changes has profound implications for young adolescents' academic and emotional thriving.

Middle Grade Schools (1980s). Research during the 1980s by Roberta Simmons and Dale Blyth showed that the transition to junior high school (as it was called then) was typically accompanied by worrying changes. Compared to students in K-8 schools, those in junior high had lower grades, lower self-esteem, and more negative attitudes about school. Other researchers (most notably Jacquelynne Eccles, Carol Midgley, and their colleagues) identified similar and additional negative outcomes, including lower achievement, perceived ability, and interest in school, less positive and personal student-teacher relationships, and more anxiety and absenteeism. Because the comparison was between students in the same grade, with only the schools' grade configuration differing, prevailing notions that hormones and puberty were responsible for students' difficulties in junior high were shown to be incorrect.

Eccles and Midgley argued that these changes were a result of a mismatch between the school environment and students' development, and they coined the term *stage-environment fit*. They noted that the nature of junior high

schools was antithetical to the developmental needs of young adolescents. That is, at a time when social connections and interpersonal relationships become particularly important, students had less opportunity for personal connections because they moved from class to class, with different teachers and different classmates and experienced predominantly whole class instruction. At a time of dramatic and uneven cognitive development, homogenous classes were formed by ability grouping and students received different learning opportunities. It was then extremely difficult for students in lower tracks to learn material necessary for college entry, and this design worked against those with later, but normal, cognitive development. Worksheets and whole class instruction predominated, so students' lessons were less varied and individualized compared to elementary school. Also of concern, junior high school teachers were less confident about teaching their students than were elementary teachers in the same grades.

When students are particularly concerned about fitting in and are sensitive about how they are viewed by others, they experienced more public and socially comparative grading practices and recognition policies. Also, although students are able to view situations more complexly, understand more abstract and nuanced ideas, and are developing their reasoning and argumentation skills, their lessons were slotted rigidly into short periods. Thus, time constrained the type and complexity of activities they could engage in. When students desire more independence and responsibility, they had fewer choices and opportunities for input. Teachers trusted students less than did elementary teachers of the same grades, and their management and discipline practices were controlling and custodial rather than student-centered.

Middle School Reform (1990s). Concern that junior high schools were not meeting young adolescents' needs led to calls for reform, with the objective of creating middle-level educational environments that are congruent developmentally with their needs. *Turning Points*, the Carnegie Council on Adolescent Development's prominent and influential report, advocated widespread changes to all aspects of the middle grades experience. The National Middle School Association advocated similar changes. Their recommendations included: (1) creating smaller learning environments to promote positive teacher-student relationships and connectedness to school (e.g., interdisciplinary team teaching, advisory programs), (2) teaching more challenging and complex material (e.g., emphasizing critical thinking skills, interdisciplinary curricula, flexible or block scheduling), (3) ensuring all students have common core classes and can be successful (e.g., heterogeneous classes), and (4) preparing teachers for the middle grades (e.g., learning about ado-

lescent development, gaining certification with a middle grade specialty).

Middle Schools between the 1990s and Early 2000s.

The middle school reform recommendations were adopted unevenly, according to reviews by the Carnegie Corporation and the RAND Corporation. Organizational changes were adopted more often than recommendations involving instruction. More than half the middle schools introduced home room classes and team teaching, however, often not as intended, thwarting objectives. For example, team teaching was premised on teachers having time together for shared planning and communicating about students, but teachers' planning times were often not coordinated. Flexible scheduling, which allows longer time periods for more complex activities, had been introduced infrequently. Integration across disciplines was difficult because teaching methods and beliefs vary for different subjects. Students continued to be placed in classes by ability groups in most schools. Although there were promising teaching reforms to increase students' conceptual understanding in mathematics and science (advocated by the National Council of Teachers of Mathematics and the National Research Council, respectively), in the early 2000s these efforts had been supplanted by consequences of high-stakes standardized testing, with its emphasis on knowledge that can be assessed quickly and easily.

Research in the 1990s and early 2000s showed that students' attitudes about school and feeling of connectedness no longer declined after the transition to middle school. Thus, the changes that targeted improving student-teacher relationships and creating a positive school climate had positive results for students. However, students did not fare better academically compared to pre-reform levels. Researchers expressed concern with the nature of instruction and the shortage of qualified teachers. Students viewed their classrooms as emphasizing learning and understanding to a lesser extent than their elementary school classrooms did.

FACTORS THAT PREDICT STUDENTS' TRANSITION EXPERIENCES

Students who are confident about themselves and their learning are most likely to experience the transition to middle school positively, whereas those who begin with academic difficulties are at risk for academic and behavioral problems. Participation in school-affiliated extracurricular activities strengthens school commitment and achievement, especially for low-achieving males. Early pubertal development is a risk factor, particularly for girls. They are more likely to experience low self-esteem, to have older friends, be sexually active, and drink

alcohol; therefore, their social lives may generate tensions with academic demands before they have developed sound coping strategies.

Friends and peers reinforce each others' actions and, therefore, support and encourage positive or negative behaviors and attitudes, depending on peer group characteristics and the intensity of the relationship. Consequently, strong friendships with peers who value school and achievement are positive predictors of transition experiences, whereas socializing with peers whose norms are counter to those promoted by school predicts future academic and social difficulties.

Students are most likely to make a positive transition to middle school when their classroom and school environments promote both their learning and understanding and supportive interpersonal relationships. This transition outcome involves a classroom emphasis on learning and understanding, not just memorization of facts, where success is viewed as self-improvement or in criterion-referenced terms, students have some autonomy, teachers have high expectations for all students, and learning activities are challenging, valued, and relevant to students. Furthermore, positive outcomes are more likely when students believe their teachers are enthusiastic and committed to helping them learn and are able to do so, feel respected as learners and as people, and view their classmates as encouraging them academically and emotionally. In contrast, competitive learning environments in which students' progress is public and expressed relative to others, and teachers' practices are controlling, inconsistent, or inflexible are likely to elicit less positive transition outcomes.

Characteristics of schools and staff affect the nature of the middle school transition. Having student-teacher advisory teams and a consistent group of classmates ease the transition. Also, having teachers who are confident in teaching their students, knowledgeable about their subject-matter and how to teach it, understand and like young adolescents, have opportunities for their own professional decision making, and feel supported by their principal and school administrators, predict middle school students' achievement and socio-emotional well-being. Conversely, students are less likely to thrive when their teachers experience high teaching demands and stress, low autonomy, and feel pressed to cover content, rather than having flexibility to pace material in response to students' understanding.

POST TRANSITION INDICATORS OF POTENTIAL DIFFICULTIES

Academic and social aspects of school are closely related; socio-emotional and behavioral difficulties lead easily to academic problems, however academic problems can pre-

cipitate poor socio-emotional well-being. In general, "standing out and not fitting in are especially detrimental during the middle school years" (Juvonen et al., 2004, p. 48). Indicators of possible difficulties are increases in absenteeism, tardiness, missed homework assignments, and declining class preparedness, interest, participation in lessons, and grades. Also, repeating a middle grade is a strong predictor of dropping out of school. Depression, with its lethargy, decreased emotionality, and sleep disturbances can lead to academic problems. Displaying problem behaviors, such as aggressiveness, disruptiveness, or impulsivity are warning signs of difficulties, as is having relationships with deviant peers. Being socially isolated increases risk for depression, interpersonal difficulties (including bullying or being bullied), poor school performance, and dropping out of school. Finally, likelihood of difficulties at middle school increases with multiple stressors; these also include stressors outside school, such as illness, financial problems, or conflict within the family, divorce, and students' job commitments.

HIGH SCHOOL

School transition research has included consideration of transitions from elementary to middle and from middle to high school as well as transitions across grades within schools and across schools in adolescence and has documented many problems for adolescents. Jacquelynne Eccles and her colleagues produced the seminal work in this area published in the *American Psychologist* (1993) as well as many other scholarly journals. She hypothesized that most middle and high schools in the United States do not meet the developmental needs of adolescents. She further argued that school transitions are largely discontinuous and disruptive for development. Much data support this hypothesis across diverse populations and strong longitudinal study designs that controlled for many confounding variables (e.g., Simmons, et al., 1987; Eccles, 2004; Isakson, & Jarvis, 1999; Gutman, & Midgley, 2000; Barber & Olsen, 2004).

Generally, students making the transition to high school experience a decrease in self-esteem, participate less in school and extracurricular activities, see a drop in grade point average, miss more school days, and suffer from anonymity. Additionally anxiety is high concerning school procedures and the presence of older peers. Yet characteristics of schools as well as differences between adolescents may influence such adjustment. According to Barber and Olsen, high school students have been assumed to have fewer problems than middle school students given that they have had experience with middle school transitions and are more mature than early adolescents, all of which makes them less vulnerable to peer influence. These authors and many others argue that these assumptions are incorrect, as high school students in middle adolescence also experience significant stressors as they strive to meet the challenges associated with school/grade transitions. The focus of this entry is on empirical findings from research on adolescent adjustment during the transition to high school.

MAJOR DEVELOPMENTAL CHALLENGES FOR ADOLESCENTS

Based on John Hill's 1983 theoretical framework for studying adolescents, biological, cognitive, and social changes are fundamental to the transition from childhood to adolescence. Such changes occur across developmental contexts, including family, peers, schools, work, and leisure. Psychosocial issues, including identity, intimacy, sexuality, autonomy, and achievement, are paramount for adolescent development as well as across the lifespan generally. Adolescents face challenges associated with these psychosocial issues as they move through adolescence and experience the fundamental biological, cognitive, and social changes across contexts that give the

issues greater significance than in childhood. Specific developmental challenges following this theoretical framework for adolescents making the transition to high school include the increased importance of academic achievement (unfortunately largely focused on grade point average) for success after graduation, the increased social significance of peer associations, and high school environments that require more self-reliance in students than was required of them in middle school.

The increased emphasis on social interactions in high school creates an environment in which fitting in and belonging serves an added source of pressure while at the same time peers (and parents) provide support for adolescents during this transitional period. Teacher expectations and demands increase in high school and students experience a higher level of stress than they did in middle school. Stark and colleagues and Phelps and Jarvis found that high school students reported their main problems to be in the areas of school, parents, friends, and dating, which is consistent with the types of developmental adjustments adolescents typically encounter and the high school atmosphere itself. Males reported more school problems, whereas females reported more interpersonal problems in both studies. Thus, adaptive coping strategies are needed by adolescents to handle such challenges. Success or failure at developmental tasks in adolescence sets the pathway for adult adjustment.

MAJOR STRUCTURAL AND ACADEMIC CHANGES IN HIGH SCHOOL

Structural changes in peer groups and schools influence the student transitioning to high school. This transition engenders changes in peer contacts such that adolescents begin to come into contact with older peers who are perceived as having more antisocial values. As with literature on early maturing adolescents, students entering the high school environment may not be prepared to cope with the influences of older, more experienced peers.

In most high schools, the structure of classes is also potentially problematic for adolescents in that classes are even less decentralized than in middle school leaving students without clear connections to caring adults who know their academic and social strengths well. Brief contact with numerous teachers in a more anonymous and bureaucratic setting makes it difficult for adolescents to feel valued and special, especially in overcrowded, resource-impooverished schools. This lack of connections to adults who can listen to adolescents' concerns undermines healthy adjustment, as Barber and Olsen discussed and the Carnegie Council on Adolescent Development noted in their task force report on preparing adolescents for the 21st century. Barber and Olsen assessed transitions to middle and high school in the same students and

found that, although in high school students reported fewer negative changes than they had two years earlier in middle school transition, the types of problems reported were consistent across both school transitions. Specifically, students perceived the school environment negatively (feeling less positive about school, feeling the need for more organization, and perceiving less support) and indicated decreased psychological adjustment (e.g., lower self-esteem, more depressive and anxiety symptoms).

Similarly, the research teams of both Simmons and Eccles noted academic changes such as stricter grading standards and structural changes common to high schools such as more impersonal environments and larger schools that increase anonymity of students. Goodenow found that students' feelings of belongingness in their school positively affected their motivation for school, effort, level of participation, and eventual achievement in school. Finally, Resnick and colleagues, reporting on the first wave of the Add Health data (a longitudinal study of adolescent health involving some 90,000 students in grades 7-12), found that both older and younger students who felt connected to their school reported less emotional distress and violent behavior. These researchers also found that a sense of connection to school protected youth from cigarette, alcohol, and marijuana use, and was associated with delay of first sexual intercourse. Both the structural and academic changes in high schools compared to middle schools alienate adolescents from school.

FACTORS PREDICTING SCHOOL TRANSITION ADJUSTMENT

Among the factors considered that predict school transition adjustment, the consensus is that a myriad of variables interact to explain variability (and resiliency) across populations of students. The main variables that have been found to predict adjustment are parent, peer, and teacher support, and development of effective coping strategies. Social class and ethnicity have also been variables identified as important mediators of adolescent adjustment. Each of these variables is considered below.

Gender differences in coping have been found that support consideration of the complexity of experience for particular adolescents. For example, Phelps and Jarvis found that females tended to use emotion-focused coping such as seeking social support; yet faced with a new, more impersonal high school environment, this coping style may not work if close friends are not present to support the adolescent in times of stress. Either new friends are needed or effective coping styles must be used. This view presumes adolescents do not make school transitions with their friends. In some instances (especially in private schools), such transitions are made from school to school as a group, and problems are less pronounced. Phelps and

Jarvis also found that adolescents identified humor and religion as possible coping strategies but did not indicate that they had used such strategies when faced with stressors; thus, one intervention option is to encourage and support the development and use of adaptive coping strategies (generally defined in the coping literature as active problem solving or seeking instrumental support more than emotional support with solvable problems) in these adolescents.

Furthermore, the role of peers is less clear if one considers the peer group's orientation toward school. Generally, peers provide support for adolescents as they face new challenges. Felner and colleagues found that the level of social support from peers and teachers was positively related to school adjustment after the transition to high school for students involved in a support project. Compared to students not involved in the project, the students in the project had higher GPAs, better attendance, more positive self-concepts, and viewed school more favorably.

Some schools have mentorship programs to help students adjust to high school transitions whereby senior students accepted into the program via an application process serve as mentors for entering freshmen (even meeting with new students before the first day of school to help them find their classes). The students then meet with their mentors (one mentor per three incoming students) weekly to acclimate to the new environment with an experienced partner. The overall effectiveness of such programs has not been adequately studied however.

Parents also play an important role in school adjustment for high school students. Fuligni and Eccles found that parents who treat their adolescents in a more adult-like fashion and grant more autonomy than in childhood ease the transition to high school more than parents who restrict opportunities for growth and development in this transitional stage. Steinberg and colleagues also noted that some parents may be experiencing midlife identity issues of their own and as a result restrict their adolescents' life choices such that their adolescents actually experience greater dependency rather than the more healthy process of becoming autonomous adults.

The role of social class must be considered as well as it is generally concluded in literature on schooling in the United States that the rich get richer and the poor stay the same or fall further behind. Similarly, in school transition literature regarding large urban schools that were resource poor, students showed increasing disengagement from school. Seidman and colleagues documented the same declines in school engagement and academics with more ethnically diverse students at such schools as had been documented previously with more middle class, less diverse, samples but also found an

increase in daily hassles for poor adolescents in poor schools that turned such adolescents even more toward their peers and gravitated toward more antisocial values. It is fairly well documented that students of color are alienated and marginalized in schools in which they are the minority and/or where tracking places them in inferior classes. Taylor and colleagues and Midgley and her colleagues argue that high schools can and must do more to support rather than undermine school engagement and motivation in students, and doing so especially needed for students who are in a racial minority in their school and even more for those minority students who also experience impoverished living conditions. Overall, poor students in poor schools in poor communities suffer the most during times of stress such as a school or life transition and are the most at risk for developmental problems associated with such stressors.

PROBLEM BEHAVIORS AFTER HIGH SCHOOL TRANSITIONS

Academic problems are the most common difficulties students experience after school transitions followed by psychological and interpersonal adjustment difficulties. These findings have been replicated across many studies in the United States as well as in Australia (see the work of Cotterell with adolescents in Australia). Some students recover from transition losses as they develop positive coping skills and if they receive parental, peer, and teacher support while other students fall further behind over the high school years and may even drop out of school. It has been difficult to adequately study such students over time as students who fell too far behind dropped out and are thus not represented in such samples.

Identifying students experiencing school transition stressors early in the first year of high school may guide interventions to prevent greater problems later. For example, students who do not feel they are a part of their school (lower sense of school membership, according to Goodenow) evince misbehavior, decreased motivation, and academic problems during high school. Although a successful transition into high school implies forming social networks with one's peers and increased support from friends may improve feelings of belongingness in the school, such support may also lead to lower academic achievement if students are distracted from academic work by spending too much time with peers.

A compromise position is to set limits such that it is clearly defined which nights of the week an adolescent may spend time with friends and which nights must be devoted to school work (this would include limits on computer and cell phone usage). Both parents and teachers should foster ongoing communication with transitioning adolescents regarding school progress.

Finally, school administrators and teachers who reach out to students suffering from anonymity and provide "a school within a school," as termed by the Carnegie Council on Adolescent Development, such that these students form appropriate close relationships with at least one adult in the school may reverse negative trajectories for such students. It is considered fundamental for intellectual and personal growth that adolescents have stable, close, mutually respectful relationships with adults and peers. Such relationships can develop best if schools support them through this or similar types of school-within-a-school contexts.

SECOND LANGUAGE ACQUISITION

Second language acquisition is learning of a nonnative language (i.e., second language) sometime after learning a native language (i.e., first language) has begun. A central characteristic defining second language acquisition is that it occurs in the context in which that language is spoken. For example, native Spanish speakers learning English in the United States or native German speakers learning Japanese in Japan are considered second language learners. However, learning a second language may or may not take place in the context of classroom instruction.

FIRST LANGUAGE VERSUS SECOND LANGUAGE

Second language acquisition is different from learning a foreign language. Second language acquisition of a nonnative language occurs in an environment in which the nonnative speaker has easy access to speakers of the language being learned. In contrast, foreign language learning refers to the learning of a nonnative language in the environment of one's native language. For example, a native English speaker learning French in the United States would be learning a foreign language (Gass & Selinker, 2001).

Understanding second language acquisition requires understanding the difference between learning a first language and a second language. First language develops without formal instruction by children being constantly exposed to language rich environments over the course of many years. The richness of the language environments in which children learn the amount of language they are exposed to and type of language they are exposed to influences how thoroughly children learn their native language. Also, as children learn their native language what they learn influences how well and how rapidly native language learning will occur (Hart & Risley, 1995). In contrast, learning a second language usually depends heavily on learning experiences in more constricted environments associated with the classroom or some other formal setting. In these settings, a major goal frequently is to formally teach children the elements of language that are learned much more informally in their native language. Consequently, assumptions regarding teaching and learning a second language are very different from assumptions about children learning their native language.

THE FIVE PRIMARY LINGUISTIC ELEMENTS.

Acquiring any language means learning five primary linguistic elements: phonology, syntax, morphology, semantics, and pragmatics. Phonology is the knowledge of the sound system in a language. It involves knowing what happens in words in fast speech as opposed to more carefully articulated speech. For example in the sentence: "I'm going to ride my bike", it is plausible that a second language learner would believe the correct pronunciation would be: "I'm goin to RIDEMYBIKE" (i.e., the learner does not articulate all of the phonemes in words and runs words together because she does not hear the words and sounds distinctly).

Phonology. Phonology includes knowing all of the sounds that are included in a language and knowing how the sounds are combined. For example, the English letter combinations *sc*, *sp*, and *st*, do not exist in Spanish at the

beginning of words. Thus, to pronounce these letter combinations, native Spanish speakers learning English tend to add an /e/ sound to the beginning of these letter combinations (e.g. /esc/, /esp/, as in *eschool*, *especial*) because in Spanish words with *sc*, *sp*, and *st* combinations begin with an /e/ sound (e.g. “*escuela*”, “*especial*”).

Syntax. Syntax is grammar, the rules that govern word order in sentences. Knowing the grammatical rules allows the speaker to produce an infinite set of sentences that can be easily understood by any individual proficient in that language. For example, the sentence: “The green turtle ran across the street to look for her friend the duck,” can be understood by proficient native English speakers even though it is unlikely that the individual has encountered this particular sentence before (Gass & Selinker, 2001).

Morphology. Morphology is the study of word formation. Morphemes represent the minimal unit of meaning in words. For example, the word *fitness* is made up of two morphemes: *fit* and *ness*. *Ness* is considered a *bound* morpheme because it can never be a word by itself, while *fit* is defined as a *free* morpheme because it is a word in and of itself like the words *man*, *woman*, and *moon*. Words can be created by adding morphemes, as in *entangle*: *dis+entangle*, *dis+entangle+ing*. The ways words are used in sentences also follow accepted patterns. For example, English speakers say, “Mt. Everest is a high mountain,” but not “The Empire State Building is a high building.” (They would say, “The Empire State Building is a tall building.”) Sometimes the reason certain word combinations are appropriate is clear, while at other times the combination appears to be quite arbitrary (Gass & Selinker, 2001).

Semantics. Semantics is the study of meaning. Knowledge of the semantics of a language also includes knowledge of the reference of words, word combinations, and limitation of word meanings. For example, in English the word *bank* has multiple meanings. When a reader encounters the word *bank* in text such as “The children sat very close to the river bank admiring the elegant movements of the swans,” he knows from the context that the word *bank* is being used to represent a margin. Knowing that words may have multiple meanings, and knowing those meanings, allows listeners and readers to interpret messages appropriately. Word combinations also affect the meaning of a sentence. For example, the meaning of the sentence: “The dog bit the man” is different from the meaning of “The man bit the dog” although both sentences include exactly the same words.

Pragmatics. Pragmatics refers to the way language is used in context. For example, when a teacher says: “Eyes on me,” a direction is being given and the expectation is that students will look at the teacher. The teacher is not suggesting she has eyes on her body somewhere. Word order has also an effect on pragmatics. For example, when a child orders a chocolate and vanilla ice cream cone, the order of the flavors may be important to understand which flavor comes first and which comes second.

The level of importance of each of these elements varies at different points in the development of language proficiency. A mature speaker of a second language uses the language differently from a novice speaker, and the differences follow predictable stages of development. For example, reading development depends on knowing the sounds in words and being able to accurately read words contained in text. Similarly, understanding the pragmatics of a language requires that second language learners understand phonology, morphology, and semantics.

THREE MODELS FOR SECOND LANGUAGE ACQUISITION

Several linguistic models attempt to explain the development of second language acquisition. The three most common models are the Universal Grammar Model, the Competition Model, and the Monitor Model. The Universal Grammar Model refers to the system of principles, conditions, and rules that are properties or elements of all human languages. At the same time, each language has grammatical rules that vary from one language to another. Thus, different languages have a limited possibility of different grammatical structures (Chomsky, 1975). Therefore, second language learners base their second language acquisition on universal principles common to all languages, and on the constraints of the particular rules of each language. For example, adjectives in English usually precede nouns. By contrast, in Spanish adjectives follow nouns. Although adjectives in both languages have the same function, their position depends on the constraints of each of the languages.

The Competition Model is based in the assumption that forms of natural language are created to communicate. Thus, second language learners are faced with the conflict between native language and target language cues and cue strengths. Learners will first resort to their native language interpretation strategies, and when these do not match the target language, then they resort to a universal selection of meaning based on cues as opposed to syntax-based cues. Positive and negative evidence is necessary for learners to realize which cues are correct for the target language (Bates & MacWhinney, 1982).

The Monitor Model (Krashen, 1985) has been very influential in school settings. This model is based on five

hypotheses: the Acquisition-Learning Hypothesis (acquisition occurs unconsciously, learning is conscious knowledge of the second language); the Natural Order Hypothesis (language rules are acquired in a predictable order); the Monitor Hypothesis (the learned system acts as a monitor of the acquired system), the Input Hypothesis; and the Affective Filter Hypothesis (motivation, attitude, self-confidence, and anxiety affect second language acquisition).

Krashen's 1985 Input Hypothesis, central to his theory of second language acquisition, suggests that language instruction just slightly above the student's current level of language proficiency (i.e., comprehensible input) is useful for second language acquisition. Generally, a silent period in the beginning of second language acquisition is natural and desirable until learners feel comfortable expressing themselves. Speaking cannot be taught directly; it is a result of internalizing comprehensible input.

Cummins (1979) hypothesized that second language acquisition includes the development of two proficiencies, conversational skills and academic language. Conversational skills (also called Basic Interpersonal Communication Skills, BICS) refer to the ability of children to use everyday language with adults and peers. The more formal academic language is the language of the classroom, as it is frequently characterized. Academic language enables students to understand and apply academic content in school. Conversational language is easier to learn and is learned more quickly than academic language.

VARIATIONS AND SUBGROUPS

Second language learners in the United States are typically referred as English language learners (ELLs). According to the National Research Council (1998), ELLs are "students who come from language backgrounds other than English and whose proficiency is not developed enough where they can profit fully from English-only instruction" (August & Hakuta, 1997, p. 15). The term Limited English Proficiency (LEP) is the formal term used by the federal government to describe and identify ELLs. The term ELLs is considered more descriptive and less pejorative than other terms (LaCelle-Peterson & Rivera, 1994; August & Shanahan, 2006). Approximately 67% of ELLs are in elementary school settings (Kindler, 2002). This statistic means that over 3 million ELLs attend elementary schools, representing more than 11.7% of the elementary school population. The vast majority of ELLs speak Spanish (79.2%) as their first language, but there are more than 460 native languages spoken by school-age students nationwide. The largest language groups after Spanish are Vietnamese

(2%), Hmong (1.6%), Cantonese (1%), and Korean (1%) (Kindler, 2002).

Approximately two out of every three ELLs reside in five states: California, Texas, New York, Florida, and Illinois. Despite this concentration of ELLs in specific states, virtually all states in the United States have seen dramatic increases in their ELL populations since 1990 when the wave of immigration to the United States rose substantially. Many of these states are experiencing the emergence of ELLs in significant numbers for the first time.

For a high percentage of ELLs, schools have difficulty providing the learning environments necessary for them to succeed academically and keep pace with their native English-speaking peers. A major challenge is teaching ELLs a second language (i.e., English) and academic content simultaneously. Since 1998 the federal government has tracked the progress of ELLs as a separate group on the National Assessment of Educational Progress. In important subjects such as reading and math, ELLs lag considerably behind other students. How to close this achievement gap concerns the research community and bilingual educators (August & Shanahan, 2006).

INTERVENTIONS AND INSTRUCTIONAL PROCEDURES TO ENHANCE EDUCATION OUTCOMES

A central question regarding ELLs acquiring English as a second language is whether it is better to teach them English language and academic content directly in English or to first make sure they have developed literacy skills in their first language. A number of research syntheses have been conducted to address this question. Francis, Lesaux, and August (2006) reviewed these syntheses and also conducted their own analysis. Although the quality of this research is not particularly strong, Francis, Lesaux, and August concluded there is a benefit to literacy development in English when ELLs are instructed in their native language (Francis et al., 2006). Overall, native language instruction resulted in a small positive impact on English reading development. They also noted the effect was strongest in those studies that paired native language instruction with English literacy instruction.

Regardless of the timing of English instruction in relation to primary language instruction, it is essential that English is taught with a strong focus placed on both learning the language and learning academic content in that language. In terms of academic content, much of the instructional approaches that are effective for native English-speaking students should also be effective for students learning English as a second language. For example, Shanahan and Beck (2006) concluded that in terms of English literacy development, the core instructional components

that are effective with native English speakers, such as phonemic awareness, phonics, fluency, vocabulary, and comprehension, are effective with students learning English as a second language. Further, many of the same instructional approaches that are effective in delivering instruction with native English speakers, such as instruction that is systematic and explicit, will be effective with second language students.

In terms of acquiring English as a second language, approaches referred to generally as sheltered instruction, in which students learn English under conditions of high language support, are advocated. In sheltered instruction, the English demands are lower than they are for native English speakers, and the acquisition of English is promoted through instruction in the language and instruction in academic content simultaneously. Frequently, however, explicit instruction in English gets less emphasis and it is more a hope that “language develop occurs” (Gersten & Baker, 2000, p. 459) during content area lessons than a clear instructional objective. This circumstance can pose a particular problem when teachers are required to cover extensive content in science, social studies, and mathematics, and there is insufficient time for English language development, particularly formal academic English.

Although the research on specific instructional variables that affect second language learning is minimal, five variables have some empirical support as well as conceptual merit: (a) vocabulary as a major curricular objective, (b) using visuals to reinforce concepts and vocabulary, (c) implementing cooperative learning and peer-tutoring strategies, (d) using native language strategically, and (e) modulation of cognitive and language demands (Gersten & Baker, 2000). Vocabulary is a key instruction target in second language learning. Vocabulary instruction should include concentration on Tier 2 words, (i.e., words that are likely to appear in a wide variety of texts and in the written and oral language of mature users (Beck, 2002). However, second language learners in the initial stages of language acquisition also benefit from instruction in Tier 1 words (i.e., words that are common in everyday life) because they frequently are not familiar to second language learners.

Using visuals and prompts helps learners visualize the abstractions of language and provide second language learners with the opportunity to practice vocabulary in formats such as small group instruction. Instructional interactions with peers increases the likelihood that information will be retained. In modulating cognitive and language demands, skillful teachers increase second language demands when students are practicing familiar academic content and decrease language demands (e.g., the use of complete sentences) when instruction focuses on the learning of new content. Strategic use of the student’s native primary language in learning new content can help second language learners attach new labels

to concepts they know in their primary language. One problem in using the student’s native language to explain concepts is that sometimes second language learners do not understand the concept in their primary language. As of the early 2000s, research in all of these areas is badly needed.

ISSUES RELATED TO ASSESSMENT AND INSTRUCTION

School-based assessments of students learning a second language are done for two broad purposes: to assess their English language proficiency and to assess their academic content knowledge. A number of problems are associated with both types of assessments, although they can provide information that is useful in school decision-making, such as identifying students for academic programs. For example, measures of English language proficiency do not predict very accurately performance on academic measures. Assessments of language proficiency also may underestimate how well students are prepared academically because performance of second language learners on academic assessments may be influenced by their knowledge of English.

Thus, low language proficiency may obscure what the learner really knows about the academic content being assessed. For example, in the early elementary grades, measures of language proficiency in English are sometimes used to delay literacy instruction until students have acquired the oral language skills considered necessary to learn academic content. A common assumption has been that teaching reading in English should occur after oral language proficiency is developed. Empirical evidence contradicts this position. Measures of oral English proficiency do not predict how well second language learners will learn English literacy skills. Even students whose oral English is very low can make significant progress learning foundations of reading in a second language such as phonemic awareness and understanding of the alphabetic principle (Chiappe, Siegel, & Wade-Woolley, 2002; Geva & Yaghouh Zadeh, 2006; Lesaux & Siegel, 2003).

In the United States, second language instruction has been heavily influenced by Krashen’s 1985 input hypothesis. However, this hypothesis has been criticized for being vague in terms of instructional specificity and lacking empirical support. Many studies have shown that speaking helps comprehension and acquisition of a second language (Pica et al., 1987; Ellis et al., 1994; Gas & Varonis, 1994; Klingner & Vaughn, 1996; Mackey, 1999). Further, in school contexts, Klingner and Vaughn (1996) suggest that providing students plenty of opportunities to practice newly learned vocabulary words in complete sentences in different contexts throughout the school day, providing immediate feedback and frequent monitoring, helps children increase English language

acquisition. In fact, several researchers have found that a major issue in instructional contexts is the lack of opportunities second language students have to use English in the classroom (Arreaga-Mayer & Perdomo-Rivera, 1996; Gersten & Baker, 2000; Ramírez, 1992). In other words, the lack of opportunities for students to engage in meaningful language use that is cognitively challenging may hinder second language acquisition.

Another issue extensively discussed has been whether there is a critical period in second language learning, generally considered to be around puberty, beyond which it is difficult or impossible to learn a second language to the same degree as a native speaker. This hypothesis suggests that young children are more likely to attain native-like proficiency in a second language than are adolescents or adults. Children appear to master the phonology of a language faster than adults, but adults appear to learn morphology and syntax faster.

However, the advantage children appear to have in attaining mastery of a second language (particularly phonology) is not uniformly apparent in all languages. Learning a second language is influenced by the alignment between the native language and the second language, and mastery of skills in the native language influences second language acquisition.

SELF-CONCEPT

SEE *Relevance of Self-Evaluations to Classroom Learning.*

SELF-DETERMINATION THEORY OF MOTIVATION

Teachers and parents frequently find themselves frustrated with their students or children, wondering how to motivate them to try harder on their schoolwork. Self-determination theory (SDT) is a broad motivational theory that addresses that issue. The theory begins by distinguishing between two different types of motivation—namely, autonomous motivation and controlled motivation—and it then considers the different consequences of these two motivations as well as their different antecedents. SDT also looks at the concept of goals as well as motivations and considers them in a differentiated manner. This entry discusses each of these ideas in turn, beginning with an explanation of the types of motivation.

AUTONOMOUS AND CONTROLLED MOTIVATIONS

Autonomous motivation involves engaging in an activity with eagerness and volition, with a sense of choice and willingness. It is made up of two subtypes: (1) intrinsic motivation, which means doing a task because it is interesting and spontaneously satisfying; and (2) identified motivation, which is a well internalized form of extrinsic motivation and involves doing the task because it feels personally important. A girl is intrinsically motivated when she takes a music class just because it is fun and challenging; a boy's motivation is identified when he studies biology because he is deeply committed to becoming a doctor.

In contrast, controlled motivation involves doing a task with a sense of pressure, demand, or coercion. It comprises two subtypes of extrinsic motivation that have not been well internalized: (1) external motivation, which means doing the activity in order to receive a reward or avoid a punishment; and (2) introjected motivation, which results from partial internalization of the extrinsic contingencies and involves doing an activity because the person would feel approved of for doing it, or guilty and unworthy for not. A boy is externally motivated when he does his homework because his parents pay him for doing it; a girl's motivation is introjected when she takes calculus because she thinks she should and would be ashamed of herself if she did not.

Both autonomy and control are types of motivation; they move students to exert energy and perform tasks. These are clearly distinct from amotivation, which means

not to be motivated for a particular activity or in a particular setting. A student who is daydreaming or paying no attention to a history lesson would be amotivated for history, at least at that time.

When one thinks about the various students in a classroom it is likely that the range of motivations will be present, for example, with some students seeming relatively autonomous and others seeming relatively controlled in their motivations. Self-determination theory focuses both on the outcomes of being more autonomous versus more controlled in one's motivation for schoolwork and on the conditions in classrooms and homes that promote the different types of motivation. Why is it, for example, that some students tend to become more interested in and committed to their school subjects over the course of an academic year, whereas other students come to value school less and become less engaged with learning over the year?

AUTONOMY AND CONTROL: THEIR CONSEQUENCES

Both types of motivation can lead to learning, but the quality of that learning is very different for the two motivations. Wendy Grolnick and Richard Ryan found, for example, that when late-elementary students tended to be autonomous in their motivation because they found the learning material interesting or because they believed the learning was personally important, the students tended to learn the material more deeply—they learned concepts rather than just memorizing facts. But if the students were studying the material because they were told they would be tested on it, they did tend just to memorize facts and not to understand how these facts fit together thematically. In short, the quality of their learning was very different, with autonomy being associated with deeper and fuller learning and control being associated with more superficial learning.

Further, Ryan, along with Richard Koestner, Frank Bernieri, and Kathleen Holt examined school children's motivation for painting pictures and found that when their motivation was more autonomous the students produced paintings that were judged to be more creative than were the paintings produced by students who were more controlled.

Several studies have also linked autonomous motivation to students' adjustment and well-being in school. For example, Grolnick and Ryan found that teachers rated students who were autonomously motivated to be more competent and to have fewer adjustment problems than students who were controlled in their motivation.

In sum, when students are more autonomously motivated because they are interested in learning the material or believe it to be personally valuable, they learn

better conceptually, tend to be more creative, and are better adjusted than when their motivation is controlled. As such, it seems very important to give careful consideration to the factors that tend to increase students' autonomous, relative to controlled, motivation.

THE ANTECEDENTS OF AUTONOMY AND CONTROL

An enormous amount of research has examined how specific events such as the offer of a reward, the provision of feedback, or the imposition of a deadline affect students' motivation. As well, many studies have explored how the general interpersonal climates in classrooms or homes influence students' motivation.

Experiments on Antecedents. Many studies have shown that giving students tangible rewards such as money, prizes, and awards for doing an activity tends to make the students more controlled rather than autonomous in their motivation for the activity. In other words, it tends to diminish their interest in the activity and also makes them dependent on the reward so they will be less likely to do the activity unless the rewards continue. In fact, Edward Deci, with Koestner and Ryan, reviewed more than one hundred experiments that examined the effects of rewards on autonomous motivation and found that overall the effects of tangible rewards were negative. Rewards can indeed prompt students to do well at school work that is routine and memory focused, but when it comes to more interesting and conceptual kinds of schoolwork, reward effects are more negative, diminishing autonomous motivation and performance. Some schools reward students with pizza parties for completing work or passing tests. Unfortunately, that is not likely to help them maintain motivation for such work. It is fine to have pizza parties, but motivationally, it is best not to make them contingent on certain behaviors or outcomes.

Other external motivators such as competition (i.e., telling students to try to beat their fellow students), evaluations (i.e., telling students that their performance will be evaluated), surveillance (i.e., watching closely at what the students are doing), and threats (i.e., telling students they will be punished if they do not do just what they are told to do) also tend to undermine the students' autonomous motivation because, like rewards, they also tend to be controlling. In contrast, offering students choice about what activities to focus on and allowing them to regulate the time they devote to each was found in an experiment to increase their interest and autonomous motivation.

The thing that ties together these various results is that the typical external motivators such as rewards, deadlines, punishments, and evaluations tend to diminish

people's sense of initiation, self-regulation, and volition, whereas offering them opportunities to make choices and guide their own activities tends to allow a greater sense of autonomy. It has become clear, from a huge amount of research, that people need to feel a sense of autonomy or self-determination in order to perform effectively and be well adjusted. In other words, based on many different studies, SDT maintains that autonomy is a basic psychological need—something that must be satisfied for people to be optimally motivated, function effectively, and be psychologically healthy. Factors that help students satisfy this need promote autonomous motivation and positive outcomes, whereas those that are likely to thwart satisfaction of this need diminish autonomous motivation and lead to poorer outcomes.

Other research related to autonomous and controlled motivations has highlighted two other basic psychological needs that are operative in people and affect their motivation. First, it seems that everyone needs to feel competent or effective in dealing with his or her environment. Accordingly, studies have shown that positive feedback enhances students' autonomous motivation because it signifies competence, whereas negative feedback decreases autonomous motivation and leaves students unmotivated. Studies also show that satisfaction of the need for competence leads people to be healthier and more effective, but thwarting of this need leads to a sense of ill-being and poorer achievement. Thus, it is important to recognize that students who get continual negative feedback about their work may get into a spiral of feeling ineffective and unmotivated, performing even worse and showing signs of poor adjustment, which leads to more of the same. Second, all people need to feel a sense of relatedness, a sense that there are other people who know and care about them. Students who feel a satisfying relationship with one or more teachers tend to do better in school than those who do not. In fact, studies have shown that feeling a sense of relatedness to important others supports the students' autonomous motivation, which in turn leads to better performance and adjustment.

Indeed, looking across a range of studies, it seems that external forces that promote satisfaction of all three needs—that is, the needs for autonomy, competence, and relatedness—lead to the most optimal school engagement and adjustment. Students who experience such need satisfaction feel a sense of vitality, interest, and flexibility; but those who do not are uninterested and disaffected, and they show signs of greater adjustment problems.

Classroom Studies. Research conducted in public schools has shown that the interpersonal climate or ambience of classrooms relates to the motivation and well-being of students in those classrooms. For example, Deci and

Ryan, with Allan Schwartz and Louise Sheinman, examined whether teachers in fourth through sixth grade classes were oriented toward controlling the students' behavior versus supporting the students' autonomy. When teachers are controlling, they make all the decisions, tell the students what they have to do, and use rewards and punishments to ensure that the students do what they the teachers demand. This is an extreme version of the traditional classroom that is sometimes called a teacher-centered classroom. Supporting students' autonomy, in contrast, means understanding and acknowledging the students' perspectives, encouraging them to take initiative and solve problems for themselves, allowing students to make choices when possible, and minimizing the use of rewards, punishments, and controlling language (e.g., "should" and "have to"). Such classrooms involve the teachers being supportive of the students' basic need satisfaction and are sometimes referred to as more student-centered classrooms.

At the beginning of a school year, Deci and colleagues did a study in which teachers completed a questionnaire from which the researchers were able to glean whether the teachers were more oriented toward controlling the students' behavior or supporting their autonomy. As well, students in those classrooms completed a set of questionnaires during the first week of school and then two months later. These questionnaires assessed the students' intrinsic motivation, feelings of competence at schoolwork, and general sense of self-worth. Results of the studies showed clear relationships between the teachers' orientations and the students' motivation, perceived competence, and self-worth. In classrooms where teachers were more oriented toward supporting the students' own motivation, the students became more intrinsically motivated and felt more competent and personally worthy, whereas in the classrooms where the teachers were more controlling the students tended to show decreases in intrinsic motivation, perceived competence, and self-worth.

Johnmarshall Reeve and Hyungshim Jang did a study in which they found that specific teacher autonomy-supportive behaviors such as being responsive to students' comments and questions, making time for students' independent work, acknowledging signs of improvement and mastery, offering progress-enabling hints when students seemed stuck, and acknowledging students' experiences and perspectives were linked positively to students' autonomous motivation.

Studies of Parents. Other studies have shown that parents' orientations toward controlling children versus supporting the children's autonomy also affected their children's autonomous motivation for schoolwork and classroom outcomes. For example, Grolnick and Ryan did in-home interviews with parents concerning how

they motivated their late-elementary-school children concerning homework and chores around the house. Mothers and fathers were interviewed separately and two interviewers rated each parent on the degree to which the responses represented autonomy support versus control. The researchers then assessed the children's autonomous motivation and perceived competence in their classrooms and gathered information from the teachers about each student's adjustment and academic competence. Results indicated that parents who were judged to be more autonomy supportive who understood their children's feelings, while supporting and encouraging them had children who reported more autonomous motivation and higher perceived competence than the children of parents judged to be more controlling. Further, the students who were rated by teachers as more academically competent and better adjusted were the ones who had more autonomy-supportive parents.

Some studies have examined students' perceptions of autonomy support from both teachers and parents and have found that each contributes predictability to students' motivation, performance, and adjustment. A study of Russian and American high school students, for example, showed that autonomy support from parents and teachers led students to be focused on learning instead of just on grades and to display greater well-being. A study of Canadians indicated that high school students' perceptions of their parents and teachers being high in autonomy support led the students to be less likely to have dropped out of school a year later.

To summarize, considerable research conducted in the psychology laboratory, in school classrooms, and in homes has indicated that external factors as well as interpersonal climates affect students' sense of volition and autonomy versus their sense of being pressure and control, as well as their school engagement, learning, performance, and psychological growth. Those teachers who are supportive of students' autonomy, competence, and relatedness enhance autonomous motivation, learning, and well-being, whereas those who thwart any of these basic needs tend to diminish the important developmental and educational outcomes.

GOALS AND STUDENT PERFORMANCE

As mentioned above, self-determination theory also studies the kinds of goals people use to guide their life pursuits. Some people, for example, place the strongest emphasis on accumulating wealth, whereas others place the strongest emphasis on having meaningful relationships. Research has shown that these types of goals can be categorized into two broad groups: extrinsic goals and intrinsic goals. For example, Tim Kasser and Ryan found that wealth, fame, and attractive image fell into the category labeled extrinsic

goals because they are concerned with external indicators of worth and do not provide direct satisfaction of the basic psychological needs. In contrast, relationships, personal growth, health, and community involvement fell into the category labeled intrinsic goals because they are satisfying in their own right and lead more directly to basic need satisfaction.

Vansteenkiste and colleagues did research that applied these goal concepts to classrooms. They introduced classroom activities by telling students that learning the material would be useful in the future either for achieving one of the extrinsic goals (e.g., making money) or for attaining one of the intrinsic goals (e.g., contributing to the community). It turned out that when learning activities were framed in terms of the intrinsic goal of helping the community, students learned the material more fully, performed better when using it, and persisted longer in learning about the topic than when it was said to be useful for making money for themselves. Further, in the experiments, the goal framing was done in either an autonomy-supportive or a controlling manner, and results indicated that intrinsic goal framing and the autonomy-supportive style each contributed to better learning outcomes. In short, orienting students learning more toward intrinsic goals and communicating with them in a more responsive and supportive way facilitates autonomous motivation, deep learning, and effective performance.

INFLUENCES ON TEACHERS' AUTONOMY SUPPORT

The fact that teachers' orientations toward autonomy support versus control in their classroom behaviors has been found to have a significant impact on students' motivation, engagement, achievement, and well-being led researchers to consider what school conditions might affect the teachers' orientations with their students. Research by Deci, Ryan, and Koestner, with Nancy Spiegel and Manette Kauffman, hypothesized that when teachers are pressured for accountability, they will tend to become more controlling with their students. The researchers then did an experiment in which teachers were given the task of teaching students how to solve a particular set of problems. In one group, teachers were told it was their responsibility to ensure that their students performed up to high standards, whereas this accountability statement was not made to teachers in another group. Results indicated that those teachers who were reminded of accountability talked much more during the teaching session, made more commands, used language that contained more control words such as "should," and, remarkably, gave the students the answers rather than giving them hints and encouraging them to find the problem solutions themselves. In short, when teachers are pressured, they in turn pressure their students

and teach in ways that have been found to be detrimental to motivation, performance, and psychological adjustment. Facilitating optimal motivation in students is thus not just an issue for teachers, for it is influenced by the school, the district, and political forces acting upon them.

Substantial research has shown that autonomous motivation, in which students read, study, and discuss their work out of interest and the belief in its importance for themselves, is the optimal motivation for deep learning, creativity, and psychological health. It is also clear that this optimal motivation requires teachers and parents to provide supports that allow students to satisfy their basic needs for feeling competence, relatedness, and autonomy by encouraging the students' initiations, respecting them as individuals, listening to their perspectives, creating opportunities for choice and self-regulation, helping out when they run into barriers, and providing positive and constructive feedback. In these ways, teachers and parents will be supporting students' motivation, engagement, achievement, and psychological well-being. When schools, districts, and states create and reinforce conditions that allow teachers to satisfy their own needs for competence, relatedness, and autonomy on the job, schools will be characterized by more effective teaching and learning.

SELF-EFFICACY THEORY

In 1986, when he put forth a social cognitive theory of human functioning, *Social Foundations of Thought and Action: A Social Cognitive Theory*, psychologist Albert Bandura painted a portrait of human behavior and motivation in which individuals' self-beliefs are critical elements. His subsequent work, *Self-efficacy: The exercise of control* (1997), advanced the discussion. Of all the beliefs that people hold about themselves and that affect their day-to-day functioning, and standing at the core of social cognitive theory, are *self-efficacy beliefs*, which can be defined as the judgments that individuals hold about their capabilities to learn or to perform courses of action at designated levels. In essence, self-efficacy beliefs are the self-perceptions that individuals hold about their capabilities.

According to social cognitive theory, self-efficacy beliefs provide the foundation for human motivation, well-being, and personal accomplishment: Unless people believe that their actions can produce the outcomes they desire, they have little incentive to act or to persevere in the face of difficulties. These self-perceptions touch virtually every aspect of people's lives—whether they think productively, self-debilitatingly, pessimistically or optimistically; how well they motivate themselves and persevere in the face of adversities; their vulnerability to stress and depression; and the life choices they make. Self-efficacy is also a critical determinant of the self-regulatory practices in which individuals engage as they go about the important task of self-correcting their actions and cognitions.

Self-efficacy beliefs should not be confused with outcome expectations, which are people's judgments of the consequences that their behavior will produce. Typically, self-efficacy beliefs help foster the outcome one expects. Confident individuals anticipate successful outcomes. Students confident in their social skills anticipate successful social encounters. Those confident in their academic skills expect high marks on exams and expect the quality of their work to reap academic benefits. The opposite is true of those who lack confidence. People who doubt their social skills often envision rejection or ridicule even

before they establish social contact. Students who lack confidence in their academic skills envision a low grade even before they begin an exam or enroll in a course. The expected results of these imagined performances will be differently envisioned: social success or greater career options for the former, social isolation or curtailed academic possibilities for the latter.

When self-efficacy belief and outcome expectation differ, the self-efficacy belief is more likely to determine the behavior. Students may well realize that strong academic skills are essential for obtaining a good SAT score and being admitted to the college of their choice, and this, in turn, may ensure a comfortable future lifestyle. But if students lack confidence in their academic capabilities, they may well shy away from challenging courses, will approach the SAT with apprehension and self-doubt, and may not even consider college attendance. In the social interaction, individuals may realize that pleasing manners and physical attractiveness are essential for attracting the attention of others, which is the first step toward building long-lasting relationships. If, however, they have low confidence in their social skills and doubt their physical attractiveness, they may hesitate to make contact and hence miss potentially promising opportunities.

Because individuals operate collectively as well as individually, self-efficacy is both a personal and a social construct. Collective systems develop a sense of collective efficacy—a group's shared belief in its capability to attain goals and accomplish desired tasks. For example, schools develop collective beliefs about the capability of their students to learn, of their teachers to teach and otherwise enhance the lives of their students, and of their administrators and policy makers to create environments conducive to these tasks. Organizations with a strong sense of collective efficacy exercise empowering and vitalizing influences on their constituents, and these effects are palpable and evident.

SOURCES OF SELF EFFICACY BELIEFS

Individuals form their self-efficacy beliefs by interpreting information primarily from four sources: mastery experience, vicarious experience, social persuasions, and physiological reactions. For most people, the most influential source is the interpreted result of one's own performance, or mastery experience. Simply put, individuals gauge the effects of their actions, and their interpretations of these effects help create their efficacy beliefs. Success raises self-efficacy; failure lowers it. Students who perform well on mathematics tests and earn high grades in mathematics classes develop confidence in their mathematics capabilities. This sense of efficacy helps ensure that they will enroll in subsequent mathematics-related classes, approach

mathematics tasks with serenity, and increase their efforts when a difficulty arises.

In addition to interpreting the results of their mastery experiences, young people form their efficacy beliefs through the vicarious experience of observing others perform tasks. Observing the successes and failures of peers perceived as similar in capability contributes to beliefs one's own capabilities (i.e., "If he can do it, so can I!"). Although this source of information is usually weaker than is mastery experience, when adolescents are uncertain about their own abilities or have limited previous experience, they become especially sensitive to it. If there is one finding that is incontrovertible in education and psychology, it is that young people learn from the actions of models, and so this is a prominent area of research in the study of self-efficacy. Vicarious experience also involves the social comparisons that individuals make with each other. These comparisons, along with peer modeling, can be powerful influences on self-efficacy beliefs. In situations in which young people have little experience with which to form a judgment of their competence in a particular area, peer models are especially useful.

Self-efficacy beliefs are also influenced by the verbal messages and social persuasions individuals receive from others, whether these are intentional or accidental. These messages can help one to exert the extra effort and persistence required to succeed, resulting in the continued development of skills and of personal efficacy. Or they can be powerfully disheartening. Persuaders play an important part in the development of an individual's self-efficacy beliefs. But social persuasions should not be confused with knee-jerk praise or empty inspirational homilies. Effective persuaders must cultivate people's beliefs in their capabilities while at the same time ensuring that the envisioned success is attainable. And, just as positive persuasions may work to encourage and empower, negative persuasions can work to defeat and weaken self-efficacy beliefs. In fact, it is usually easier to weaken self-efficacy beliefs through negative appraisals than to strengthen such beliefs through positive encouragement.

Physiological and emotional states such as anxiety and stress, along with one's mood, provide information about efficacy beliefs. Typically, optimism or a positive mood enhances self-efficacy, whereas depression, despair, or a sense of despondency diminishes it. As with the other sources, it is not the intensity of the physical indicator or mood state itself that is important, but the individual's interpretation of it. Adolescents with strong self-efficacy will view the emotional state as energizing, whereas those beset by self-doubt may regard it as debilitating.

MOTIVATIONAL CONSEQUENCES OF SELF EFFICACY BELIEFS

Self-efficacy beliefs can enhance human accomplishment and well-being in countless ways. They influence the choices people make and the courses of action they pursue. Individuals tend to select tasks and activities in which they feel competent and confident and avoid those in which they do not. Unless people believe that their actions will have the desired consequences, they have little incentive to engage in those actions. How far will an interest in medicine take a student who feels hopeless while studying anatomy? Whatever factors operate to influence behavior, they are rooted in the core belief that one has the capability to accomplish that behavior.

Self-efficacy beliefs also help determine how much effort people will expend on an activity, how long they will persevere when confronting obstacles, and how resilient they will be in the face of adverse situations. People with a strong sense of personal competence approach difficult tasks as challenges to be mastered rather than as threats to be avoided. They have greater intrinsic interest and deep engrossment in activities, set themselves challenging goals and maintain strong commitment to them, and heighten and sustain their efforts in the face of failure. Moreover, they more quickly recover their sense of efficacy after failures or setbacks.

Self-efficacy beliefs also influence an individual's thought patterns and emotional reactions. High self-efficacy helps create feelings of serenity in approaching difficult tasks and activities. Conversely, people with low self-efficacy may believe that things are tougher than they really are, a belief that fosters anxiety, stress, depression, and a narrow vision of how best to solve a problem.

Human motivation, cognition, and behavior are influenced by many factors. The success or failure that people experience as they engage the myriad tasks that comprise their life naturally influence the many decisions they must make. Also, the knowledge and skills they possess will certainly play critical roles in what they choose to do and not do. But people must invariably interpret the results of their attainments, just as they must make judgments about the quality of the knowledge and skills they possess. Imagine, for example, two students who receive a B on an important mathematics exam. In and of itself, a B has no inherent meaning, and certainly no causal properties. How will receiving such a grade affect a particular student? A student accustomed to receiving A's in math class and who worked hard throughout the term and studied for the exam will view the B in ways quite dissimilar from those of a student accustomed to receiving C's and who worked equally hard. For the former, the B will be received with distress; for the latter, the B is likely to be received with

elation. The student accustomed to receiving A's is likely to have bruised self-efficacy; the C-acquainted student is sure to have boosted self-efficacy.

SELF EFFICACY BELIEFS AND ACADEMIC ATTAINMENTS

Self-efficacy has been the focus of research in areas as diverse as business, athletics, medicine and health, media studies, social and political change, moral development, psychiatry, psychopathology, and international affairs. In psychology, it has been the focus of studies on clinical problems such as phobias, depression, social skills, assertiveness, smoking behavior, and moral development. Self-efficacy has been especially prominent in educational research, where scholars have reported that, regardless of previous achievement or ability, self-efficacious students work harder, persist longer, persevere in the face of adversity, have greater optimism and lower anxiety, and achieve more. Students who believe they are capable of performing academic tasks also use more cognitive and metacognitive strategies than those who do not. Academic self-efficacy influences cognitive strategy use and self-regulation through the use of metacognitive strategies, and self-efficacy is associated with in-class seatwork and homework, exams and quizzes, and essays and reports.

In psychology, intelligence (in the form of IQ) has typically been acknowledged the most powerful cognitive predictor of achievement. But when researchers tested the joint contribution of self-efficacy and intelligence to the prediction of achievement, they found that students' self-efficacy beliefs made a powerful and independent contribution to the prediction of their academic performance. Self-efficacy is also a critical determinant of the life choices that students make and of the courses of action they pursue. Typically, they engage in activities in which they feel competent and avoid those in which they do not. Doing so is particularly critical at the high school and college levels, where young people progressively have more academic options.

Students with high self-efficacy engage in more effective self-regulatory strategies at differing levels of ability, and self-efficacy enhances students' memory performance by enhancing persistence. In studies of college students who pursue science and engineering courses, high self-efficacy has been demonstrated to influence the academic persistence necessary to maintain high academic achievement.

In general, researchers have established that self-efficacy beliefs and behavior changes and outcomes are highly correlated and that self-efficacy is an excellent predictor of behavior. The depth of this support prompted Graham and Weiner (1996) to conclude that, particularly in psychology and education, self-efficacy has proven to be

a more consistent predictor of behavioral outcomes than have any other motivational constructs.

IMPLICATIONS FOR TEACHERS AND SCHOOLS

The first and major implication that arises from research findings on the role and function of self-efficacy beliefs in academic contexts is that teachers do well to take seriously their share of responsibility in nurturing the self-efficacy beliefs of their pupils, for it is clear that these beliefs can have beneficial or destructive influences. Bandura has argued that beliefs of personal competence constitute the key factor of human agency, the ability to act intentionally and exercise a measure of control over one's environment and social structures. As children strive to exercise control over their world, their first transactions are mediated by adults who can empower them with self-assurance or diminish their fledgling self-beliefs. Because young children are not proficient at making accurate self-appraisals, they naturally rely on the judgments of others to create their own judgments of their capabilities. Teachers who provide children with challenging tasks and meaningful activities that can be mastered, and who chaperone these efforts with support and encouragement, help ensure the development of a robust sense of efficacy. Effective teachers know their students' capabilities. They also know that trying very hard and continually failing can have a devastating effect on one's confidence. For this reason, they are careful to assign work that will indeed be challenging but that they are sure can be accomplished with proper effort.

An incontrovertible finding in educational research is that students learn from the actions of models. Different modeling practices in school can differently affect self-efficacy beliefs. For example, when models make errors, engage in coping behaviors in front of students, and verbalize emotive statements reflecting low confidence and achievement (such as "Gosh, I seem to be having some trouble with this, don't I?"), low-achieving students perceive the models as more similar to themselves and subsequently experience greater achievement and self-efficacy under their tutelage. Social cognitive theorists recommend that teachers engage in effective modeling practices and that they select peers for classroom models judiciously so as to ensure that students view themselves as comparable in learning ability to the models. Peer models should also share similar attributes to the students for whom they are serving as models.

Children inevitably compare themselves to other children, and these social comparisons are critical to the development of self-efficacy beliefs. Social-comparative school practices that emphasize standardized, normative assessments, involve ability grouping and lock-step instruction,

use competitive grading practices, and encourage students to compare their achievement with that of their peers work to destroy the fragile self-beliefs of those who are less academically talented or prepared. As Bandura (1997) has noted, these are practices that can work to convert “instructional experiences into education in inefficacy” (p. 175).

When classroom structures are individualized and instruction is tailored to students’ capabilities, social comparisons are minimized and students are more likely to gauge their academic progress according to their own standards rather than compare it to the progress of their classmates. In cooperative and individualized learning settings, students can more easily select the peers with whom to compare themselves. Individualized and cooperative structures that lower the competitive orientation of a classroom and school are more likely than traditional, competitive structures to increase self-efficacy. Similarly, classrooms that emphasize a mastery goal orientation, which is to say that they emphasize the view that learning is an enjoyable activity and should be undertaken for its own sake rather than for extrinsic or performance oriented reasons, also have beneficial effects on students’ self-efficacy beliefs.

Some researchers have suggested that teachers should pay as much attention to students’ perceptions of competence as to actual competence, for it is the perceptions that may more accurately influence students’ motivation and future academic choices. Assessing students’ self-efficacy beliefs can provide teachers with important insights about their pupils’ academic motivation, behavior, and future choices. For example, unrealistically low self-efficacy, not lack of capability or skill, can be responsible for maladaptive academic behaviors, avoidance of courses and careers, and diminishing school interest and achievement. Students who lack confidence in skills they possess are less likely to engage in tasks in which those skills are required, and they will more quickly give up in the face of difficulty. In such cases, in addition to continued skill improvement, schools must work to identify their students’ inaccurate judgments and design and implement interventions to challenge them. Researchers have identified various ways in which self-efficacy perceptions can be challenged. For example, teachers can set goals for students that are close at hand rather than goals that require a large investment in time. Teachers can also provide frequent and appropriate feedback as students are engaged in a task. Of course, it has been amply shown that effort-focused feedback (such as “Well done, you’re working hard.”) enhance students’ self-efficacy and performance to a greater degree than does ability-focused feedback (such as “Well done, you’re so smart.”).

It seems clear that many of the difficulties that people experience throughout their lives are closely con-

nected with the beliefs they hold about what they can and cannot do. Sound research evidence suggests that students’ academic failures in basic subjects, as well as the misdirected motivation and lack of commitment often characteristic of the underachiever, the dropout, the student labeled at risk, and the socially disabled, are in good measure the consequence of, or certainly exacerbated by, the beliefs that students develop about their ability to exercise a measure of control over their environments.

Empirical findings have amply strengthen the claim of social cognitive theorists that self-efficacy beliefs play an influential role in human agency, and they support the contention of theorists and researchers that students’ self-efficacy beliefs in academic areas powerfully influence their subsequent motivation and performance in these areas. Clearly, researchers and school practitioners should continue to look to students’ beliefs about their academic capabilities as important predictors and determinants of academic achievement, for they are critical components of motivation and behavior.

SELF-ESTEEM

Self-esteem refers to an individual’s or in some cases a group’s evaluative judgment about himself, herself, or itself. The term and concept were relatively unnoticed prior to the 1960s, at which time various thinkers and researchers began to suspect that it could be an important factor in behavior. By the late 1970s self-esteem had become a major focus of a great deal of research, and people began to seek to raise self-esteem in connection with a broad assortment of interventions, including clinical practice and education.

During the 1980s self-esteem became a national buzzword and was being studied and applied in a staggering variety of settings. Leading proponents such as Nathaniel Branden (1984) contended that deficient self-esteem was a causal factor behind nearly every sort of personal and social problem and pathology. A high point of sorts was reached late that decade, when the state of California established the California Task Force to Promote Self-esteem and Personal and Social Responsibility. Its manifesto (California Task Force, 1990) asserted that raising the self-esteem of California's citizens would help solve many of the state's problems, including violence, drug abuse, unwanted pregnancy, and school underachievement.

Criticism began to mount in the 1990s, and since the early 2000s the value of self-esteem has become the focus of serious debate. As of 2008 there are many programs for boosting self-esteem, especially among schools, and some groups whose livelihoods depend on administering these are fiercely resistant to criticism. On the other side, accumulated research findings have led many experts to question whether high self-esteem or boosting self-esteem has any practical value at all. Most likely an intermediate conclusion is correct.

In 1999 the American Psychological Society (subsequently renamed the Association for Psychological Science) commissioned a panel of experts to review the research findings and provide a summary evaluation of the benefits of high self-esteem. The governing board sought to compose the panel of persons with widely different initial views about self-esteem (i.e., both proponents and critics) and selected a leader (Baumeister) who had held different opinions at different times, reflecting a presumptive willingness to revise his opinions in light of new evidence. Its report filled an entire issue of the journal *Psychological Science in the Public Interest* (Baumeister, Campbell, Krueger, & Vohs, 2003). That report, and a condensed version for lay readers published by the same authors in *Scientific American* in January 2005, offers a relatively thorough overview for interested readers.

DEFINITION AND MEASUREMENT

Self-esteem literally means a person's valuing of himself or herself. It is thus the evaluative dimension of the self-concept. This may include both thoughts and feelings. Related terms include self-love, self-worth, self-respect, self-regard, and narcissism.

Self-esteem is typically measured with a questionnaire inviting respondents to rate how they think and feel about themselves. For better or worse, the brief scale developed by Rosenberg (1965) has become the standard way of measuring self-esteem. Items on self-esteem scales typically include assessment of liking for oneself overall, appraisal of one's confidence at being able to perform

well at work and in school, and ability to get along with others and be liked. Moral self-appraisals are included in some scales.

Self-esteem is thus opinion, not objective appraisal. High self-esteem may refer to accurate, healthy appreciation of one's genuine capabilities and worth as a person, or it may refer to unrealistic, conceited overestimates of the self. Efforts to distinguish inflated egotism or narcissistic conceitedness from so-called true self-esteem have not had much success thus far. One general implication, therefore, is that several different kinds of people score high in self-esteem.

Nearly all research samples find that self-esteem, at least among modern Americans, is relatively high on average. That is, the distribution of scores runs from close to the maximum possible score on the scale down to a bit below the scale midpoint, with then relatively few scores in the bottom register. When researchers compare high and low scores on self-esteem, they divide the sample in its middle, but some critics have suggested that this in effect compares truly high self-esteem against medium self-esteem. Nonetheless, the distribution refutes widespread claims that the American population suffers from an epidemic of low self-esteem. In fact, American self-esteem scores have long been relatively high and have been increasing steadily in recent decades (Twenge & Campbell, 2001).

One important question is whether self-esteem should be measured as a general attitude toward the self overall or, instead, in specific domains. It seems eminently possible for a person to believe himself or herself to be good at math and poor at music; is there a core overall evaluation of self that coexists with these? Most research has focused on global self-esteem, but there are notable exceptions, particularly the work of Herbert Marsh (e.g., 2006), which focuses on academic self-esteem and indeed sometimes emphasizes self-esteem as separate for specific areas of study.

A persistent source of bias in the research literature stems from relying on self-reports. People score high in self-esteem by saying favorable things about themselves on a questionnaire, and so people who tend to flatter themselves on questionnaires end up classified as high in self-esteem. That may sound obvious, but many researchers then give people another questionnaire to ask about other sorts of behaviors and attributes, and when these same people say favorable things about themselves on those questionnaires, researchers sometimes mistakenly conclude that self-esteem contributes to positive outcomes. For example, when researchers ask people how intelligent or physically attractive they are, people with high self-esteem rate themselves higher than those with low self-esteem, which seemingly suggests that high

self-esteem is linked to intelligence and good looks. But when researchers get objective data (e.g., giving an IQ test, or having judges rate how good-looking participants are), those differences disappear completely.

BENEFITS OF HIGH SELF ESTEEM: SCHOOL PERFORMANCE

Much interest in self-esteem was stimulated by the claim that raising self-esteem could contribute to improving schoolwork. Although these hopes appear now to be false, they were plausible. In theory, high self-esteem might improve performance by increasing confidence, by making people willing to persist despite initial failure, by means of self-fulfilling prophecies, by eagerness to seek out challenges, and by other means. These hopes have been fueled by persistent findings that correlate self-esteem with grades in school and test performance, typically around .21 to .26, as noted already by Hansford and Hattie (1982), though the results varied widely from one study to another.

The fact that students with higher grades have higher self-esteem does not necessarily mean that bolstering self-esteem will cause other students to improve performance, however, for two reasons. The first reason is the familiar gap between correlation and causation. High self-esteem appears to be the result, not the cause, of doing well in school, as gradually emerged from painstaking longitudinal studies (e.g., Bachman & O'Malley, 1977). In other words, the good grades come first, and high self-esteem follows, so boosting self-esteem to improve grades may be backwards and hence futile.

Second, even if there were direct causal links between a stable trait of self-esteem and school performance, this does not guarantee that artificially boosting the trait or attitude will lead to improvements in performance. The many programs aimed at increasing self-esteem among students have generally failed to provide any evidence that they improve learning. An early review of such interventions and programs by Scheirer and Kraut (1979) concluded that such interventions were not effective. Subsequently, many professional programs advertised as bolstering self-esteem among students have added modules on study skills and socially desirable behavior, seemingly in tacit acknowledgement that self-esteem boosting alone does not work, but programs originating in the schools themselves may not uniformly recognize this need.

Almost no studies have employed experimental designs with proper controls to investigate the effects of boosting self-esteem. One exception was reported by Forsyth, Kerr, Burnette, and Baumeister (2007). College students with C, D, or F midterm grades were randomly assigned to receive weekly messages containing (1) review questions, (2) review questions plus self-esteem boosting,

or (3) review questions plus reminders to take personal responsibility. Students whose self-esteem was boosted actually got significantly poorer grades on the final examination than on the midterm and poorer than students in the control condition. Thus, boosting self-esteem actually caused a significant decline in performance. The authors were surprised by this result and wished to conduct further studies, but obviously it would be unethical to conduct research that expects to cause students to get bad grades. Still, this result should give pause to anyone interested in improving school performance. Some have pointed out that the widespread embracing of self-esteem in school curriculums has coincided with a general decline in American student performance, though drawing firm causal conclusions from mass societal phenomena is generally unwarranted, especially in comparison with controlled experimentation.

Why might self-esteem cause school performance to get worse? Even proponents of self-esteem such as Nathaniel Branden have begun to suggest that self-esteem has most positive effects when it is earned via legitimate accomplishment. Hence simply telling people to think they are wonderful in the absence of such achievement may foster a sense of being too good to be willing to work hard or other sorts of entitlements. Overconfidence is also a possibility.

OTHER POTENTIAL BENEFITS OF HIGH SELF ESTEEM

Self-esteem has been investigated for a variety of possible benefits beyond school performance. Given the limited space, this entry provides only a brief overview: For a more thorough review, see Baumeister and colleagues (2003).

Interpersonally, people with high self-esteem report and consider themselves to be charming and popular, with good relationship skills and many friends, but when they are rated by other people, most of these advantages disappear. In laboratory studies that assign people to interact with strangers and then report their impressions, high self-esteem persons generally think they have made better impressions than people with low self-esteem, but the actual impressions are no different or in some cases worse.

A longstanding view has surmised that violence and aggression stem from low self-esteem, but the actual evidence for this is extremely sparse and consists mainly of self-reports. Behavioral studies generally find self-esteem to make no difference and people high in narcissism, which can be regarded as one of the less appealing kinds of high self-esteem, are the most aggressive, especially when someone has criticized them. Thus, violence stems more from threatened egotism than from inadequate self-love (Baumeister, Smart, & Boden, 1996). There is some evidence of a correlation between some forms of delinquent,

externalizing, antisocial behavior and low self-esteem, though it is not known which causes which.

The effects of self-esteem on work and task performance resemble those on school performance. Self-reports vary widely but generally point toward a mildly positive relationship, possibly because people with high self-esteem are prouder of their work than are people low in self-esteem. Objective data on task performance generally show little or no difference, with one important exception: High self-esteem leads to better persistence in the face of failure than low self-esteem, as shown in many studies.

Happiness is correlated with high self-esteem. Obviously these studies rely on self-reports of happiness (because no objective measures exist), but the pattern seems robust across many methods and samples, and experimental manipulations that raise or lower self-esteem produce corresponding emotional changes to support the conclusion. There is also a longstanding hypothesis that high self-esteem acts as a buffer to shield the person from the harmful effects of stress and trauma, and some rigorous studies have supported that conclusion. Although other studies have shown somewhat different patterns of results, none finds that low self-esteem leads to better coping or more happiness. Low self-esteem is persistently correlated with depression, though it is very difficult to say which causes the other.

The hope that high self-esteem would help young people resist smoking, drug abuse, early sexual behavior, and other unhealthy patterns has not generally been supported. If anything, more findings link high than low self-esteem to early experimentation with sex and drugs, possibly because popularity contributes to both high self-esteem and experimentation. Among all these domains surveyed by Baumeister and colleagues (2003), the best results were found with eating disorders. Low self-esteem appears to be a risk factor that significantly increases the risk that young women and possibly young men will develop eating disorders, though the effect of self-esteem is only in combination with other factors and possibly indirect.

Overall, two benefits of high self-esteem stood out. High self-esteem promotes initiative, presumably because confidence makes people more willing to take action and rely on their own judgment. This can produce negative effects, but initiative is mostly considered a good thing, and so this is one important benefit.

The other benefit is positive feelings and happiness. High self-esteem seems to be linked to a stock of pleasant, happy feelings that enable the person to enjoy life when it is good and/or avoid depression and misery when things are not going well.

Although these two established benefits of high self-esteem fall far short of what was once hoped, they are far

from trivial, and in combination they can contribute to making life good for people whose self-esteem is high. The question of how much effort and other resources should be devoted to boosting self-esteem in order to increase these two benefits is left to policymakers. It is however noteworthy that these benefits of high self-esteem accrue mainly to the individuals rather than to their relationship partners or to society as a whole. Some experts caution that simply flattering young people or otherwise seeking to boost their self-esteem directly will more likely contribute to increased narcissism and other less desirable forms of self-esteem, and the societal consequences of narcissism (which has been increasing throughout the U.S. population in the last decades of the 20th century; Twenge & Campbell, in press) are if anything negative.

UNDERSTANDING SELF ESTEEM

The question of what are the benefits of high self-esteem is hardly the only important question about self-esteem. Considerable work has been invested in understanding how the behavioral, mental, and emotional reactions of people with high self-esteem differ from those with low or medium self-esteem. Presumably most educators and other leaders will have to deal with people having a variety of levels of self-esteem, and so understanding these differences may be useful for helping them deal effectively with each individual.

In general, low self-esteem is a greater puzzle than high self-esteem. Researchers have found it relatively easy to characterize people with high self-esteem, who like themselves and generally expect life to go well. Competing theories about low self-esteem have flourished, however.

Regarding emotional differences, high self-esteem is associated with generally higher levels of happiness and good feelings than low self-esteem (as noted above). Another difference is in emotional lability (Campbell, Chew, & Scratchley, 1991). People with low self-esteem have more frequent emotional ups and downs. This may indicate that people with low self-esteem lack the stabilizing influence that is associated with the emotional resources that go with high self-esteem.

Regarding cognition, people with low self-esteem experience more uncertainty and instability of self-knowledge (Campbell, 1990). Their self-concepts fluctuate more than those of people with high self-esteem. They are more likely to describe themselves in inconsistent and contradictory ways and to change how they rate themselves from one time to another. They are also more likely to respond "I don't know" to questions about themselves. This is an important clue to the nature of self-esteem. High self-esteem means having firm, clear ideas about who one is and what one wants. Low

self-esteem does not apparently mean being convinced that one is a bad person. Instead, it is the absence of well-defined positive views of self rather than the presence of well-defined negative views.

People with high self-esteem engage in many self-flattering biases, such as assuming and in many cases overestimating how much that others will agree with their opinions and that their abilities are unique. They take credit for success and deny blame for failure. People with low self-esteem have fewer such biases. These mental tricks contribute to some of the biases noted earlier, such as that people with high self-esteem consider themselves smarter, more popular, and better-looking than other people, whereas objective evidence generally disconfirms these self-flattering views. Thus, an essential part of high self-esteem in many cases is convincing oneself that one is better than one really is.

Turning to motivation, what do people with low self-esteem want? Mostly they do not seek failure and rejection. Instead, they seem to want the same things that people high in self-esteem want (such as success and social approval), but they are less certain than others that they will achieve these goals (McFarlin & Blascovich, 1981).

The level of aspiration is different, and as a result, the overarching social motivations are different. People with high self-esteem want and expect to succeed, and so they are willing to take chances to stand out. They have a self-enhancing orientation, which means they look for ways to increase their stock of successes and to improve how others see them. In contrast, low self-esteem is associated with a prevention orientation: These people go through life seeking to remedy problems and avoid failures. They may focus on their weaknesses (whereas people with high self-esteem focus on their strengths) and avoid risky situations (for review, see Baumeister, Tice, & Hutton, 1989).

People with low self-esteem lack confidence in their own views and ideas, and so they are relatively willing to do what others tell them. Indeed, some of the earliest research on self-esteem emphasized that low self-esteem produces a relatively high susceptibility to persuasion and influence (Janis, 1954; for review, see Brockner, 1983). The behavior of these people varies across situations as they yield to current pressures. High self-esteem, in contrast, tends to promote acting on one's own and disregarding the influences and even the good advice of others.

Abundant research has shown that people desire high self-esteem: They strive to think well of themselves. Why is the concern with self-esteem seemingly so deeply rooted in the psyche? If high self-esteem conferred many positive benefits, the desire for it would be understandable, but given the relatively few advantages, it presents a puzzle. Noting that high self-esteem feels good provides a

partial answer, but because emotions are presumably there to help people survive and prosper, the question again arises, why are emotions tied to self-esteem?

One answer offered by Mark Leary and his colleagues is that self-esteem is a kind of internal measure of something that is vitally important, namely one's prospects for social acceptance (Leary, Tambor, Terdal, & Downs, 1995). High self-esteem is typically based on thinking one has the traits that will bring acceptance: attractiveness, likeability, and competence. Low self-esteem in this view is essentially a belief that one does not have what it takes to attract and keep relationship partners and group memberships. Human survival has long depended on belonging to important groups, and so self-esteem may be one's internal measure of how likely that is.

SELF-EVALUATIONS

SEE *Relevance of Self-Evaluations to Classroom Learning*.

SELF-EXPLANATION

Simply defined, learning involves the use of existing knowledge to make meaning of new information (Driscoll, 2000). The process of explaining to-be-learned materials to oneself has been called *self-explanation* and is considered to be a constructive activity (e.g., Calin-Jageman & Ratner, 2005; Tajika, Nakatsu, Nozaki, Neumann, & Maruno, 2007). Self-explanation facilitates learning in one of two manners. The process prompts students to form inferences beyond the provided information, extending and supporting their knowledge revision (McNamara, 2004; Taboada & Guthrie, 2006). This form of self-explanation helps students compensate for text inadequacies, inconsistencies, and incompleteness. Self-explanation also encourages students to revise their current understandings of concepts by prompting them to compare their inaccurate and/or incomplete understandings with those presented in text. New learning unfolds as students attempt to reduce inconsistencies between their existing knowledge structures and new information (Ainsworth & Burcham, 2007).

EFFECTIVENESS OF SELF EXPLANATIONS

In their seminal work, Chi and colleagues (Chi, Bassok, Lewis, Reimann, & Glaser, 1989; Chi & Bassok, 1989) instructed undergraduate students to provide self-explanations in response to worked examples. The researchers observed that undergraduates who demonstrated proficiency in problem solving (82% correct or higher) produced twice as many self-explanations, confirming earlier findings that providing justifications for solution steps while problem solving improves learning (e.g., Gagné & Smith, 1962). Moreover, Chi and colleagues observed that the nature of students' explanations differed qualitatively. Successful problem solvers provided self-explanations that refined, defined, and expanded action components of the examples, and used them as references to principles and concepts outlined in the text. These students' explanations indicated self-monitoring of new understandings and misunderstandings. Students who were less successful problem solvers generated insufficient and/or superficial explanations and did not monitor their learning with subsequent analyses confirming these distinctions (Chi & VanLehn, 1991; Renkel, 1997). Equally important, these studies revealed that, in the absence of specific instructions or supports, most students either do not generate self-explanations or generate superficial ones only (e.g., Atkinson, Renkl, & Merrill, 2003; Chi & Bassok, 1989; Chi, Leeuw, Chiu, & LaVancher, 1994; McNamara, O'Reilly, Best, & Ozuru, 2006; Schworm & Renkl, 2007).

Findings from earlier research documented that undergraduates who generated self-explanations demonstrated greater learning than students who did not produce self-explanations. However, they learned less overall than students who were provided with expert-generated explanations (Stein & Bransford, 1979). Closer analysis revealed that expert-generated effects were limited to instances in which students generated imprecise elaborations, corroborating that self-explanation effects are contingent on having students produce meaningful explanations that either establish connections between text ideas or integrate them with relevant prior knowledge (Chi, 2000; King & Rosenshine, 1993; McNamara & Kintsch, 1996; Rosenshine, Meister, & Chapman, 1996; Scardamalia & Bereiter, 1992).

The quality of instructor-generated explanations is also an important instructional factor. When experts or instructors verbalize "why-type" explanations, they encourage students to practice self-explanation. This is especially true when working with young students (Crowley & Siegler, 1999; Peters, Messer, Smith, & Davey, 1999; Pine & Messer, 2000; Siegler, 1995). When prompted to describe the instructor's problem-solving strategy, kindergarten students produced superior self-explanations and used this problem-solving strategy more frequently than did students

who responded to their own thinking (Calin-Jageman & Ratner, 2005). Modeling provides students with the opportunity to reflect on instructors' rationales and reasoning, and provides them with opportunities to gain proficiency in the use of self-explanation.

There is substantial evidence that all students can be taught to produce self-explanations and that doing so produces subsequent learning gains relative to not doing so or being provided with generated explanations (post-secondary: Alevan & Koedinger, 2002; Bielaczyc, Pirolli & Brown, 1995; de Bruin, Rikers, & Schmidt, 2007; Reimann & Neubert, 2000; secondary: Chi et al., 1994; Siegler, 2002; Wong, Lawson & Keeses, 2002; elementary: Davis, 2003; Tajika & Nakatsu, 2005; Tajika, Nakatsu, & Nozaki, 2006). For example, Rittle-Johnson's 2006 study (2006) demonstrated that students in grades 3 to 5 were able to solve more mathematical equivalency problems following instructions to generate self-explanations than were students who were not provided with such instructions. Students' learning gains held across measures of immediate and delayed learning and were especially pronounced for measures of procedural learning and transfer.

ENHANCING QUALITY OF SELF EXPLANATIONS

Providing students with instruction in the use of specific thinking prompts and learning strategies can enhance the quality of self-explanation. The use of thought-provoking question stems is one technique for assisting students to generate quality self-explanations when processing text independently, in pairs or in small groups (King, 1989; 1990; 1991; 1992; 1994). Question stems are based on higher-level thinking skills and are intended to encourage students to draw upon their existing knowledge to generate applications (e.g., "How would you use _____ to _____?"), explanations (e.g., "Explain why . . .") evaluations (e.g., "Which one is the best _____ and why?"), and other forms of higher-level thought (e.g., "What do you think would happen if . . .?"). Students who generate self-explanations that extend beyond the literal level of the text demonstrate enhanced retention and understanding (e.g., National Reading Panel, 2000; Taboada & Guthrie, 2006).

Students have also benefited from receiving instruction intended to promote the use of multiple strategies that promote self-explanation and metacognitive awareness (McNamara, 2004). McNamara found that undergraduates instructed to generate elaborations and predictions, use logic, make bridging inferences, and paraphrase and monitor comprehension, demonstrated superior learning for unfamiliar materials compared to their uninstructed peers. They titled their program the

Self-Explanation Reading Training (SERT). While students with high and low levels of prior knowledge benefited from instruction, gains were especially pronounced for participants with low prior knowledge when responding to text-based questions.

Self-explanation may benefit certain students more than others. Specifically, students who possess relatively low levels of prior knowledge demonstrate greater learning following self-explanation than those with higher levels of prior knowledge (Renkl, Stark, Gruber, & Mandl, 1998). The former group of students typically do not activate prior knowledge or engage in other elaborative processes during new learning experiences (McNamara, 2001; McNamara & Kintsch, 1996). Presumably, engaging in the process of self-explanation is more helpful for these students than their peers who possess higher levels of prior knowledge as it encourages them to adopt strategic processes while studying and allows them to maximize working memory capacity (Best, Rowe, Ozuru & McNamara, 2005). There is also evidence that the accuracy of the self-explanation does not dramatically affect students' learning gains. That is, the process of producing self-explanations, regardless of the accuracy of the explanations, seems sufficient to enhance the learning process. To this end, some researchers have argued that the process of generating self-explanations itself induces greater understanding of domain principles (Chi, 2000; Chi & VanLehn, 1991).

Having instructors or experts provide students with instructions to produce self-explanations is not always feasible. However, research supports the conclusion that paraprofessionals and tutors can also promote processing that involves self-explanation. Students working with tutors trained to prompt self-explanation demonstrated superior learning relative to those whose tutors engaged in the typical processes of initiating questions, providing constructive feedback and assessing comprehension. Presumably, scaffolding and prompting in this manner encourages students to control their own learning. Self-explanations in tutoring are especially conducive to addressing students' misconceptions (Anderson, Boyle & Reiser, 1985; Chi, 1996; Chi, Siler, Jeong, Yamauchi, & Hausmann, 2001).

Peers can also encourage each other to generate self-explanations (Chin & Brown, 2000; Minick, 1989). For instance, Webb and her colleagues (Webb, 1991; Webb & Palincsar, 1996) demonstrated that students can be trained to encourage explanations from each other (rather than provide responses) when working in cooperative learning groups. In these learning situations, how instructors interact with students as part of their large group instruction influences the nature of small group interactions (Webb, Nemer, & Ing, 2006). If students are encouraged to

verbalize their thinking or ask “why-type” questions as part of teacher-led instruction, they are also likely to adopt these behaviors as part of small group interactions. In essence, students’ small-group behaviors mirror instructors’ discourse and expectations (Webb et al., 2006). Instructional environments that are entrenched in cultures of low-level questions and sparse explanations produce long-term learning effects that are difficult to overcome.

USING COMPUTER MODELS TO REPRODUCE SELF EXPLANATION EFFECT

Computer-based learning environments also provide alternative instructional venues for the promotion of self-explanations. One of the earliest computer models devised to account for and reproduce the self-explanation effect through the use of analogies was Cascade (VanLehn, Jones, & Chi, 1992). More recent computer-based learning environments provide students with tutorial-like dialogues that analyze their explanations while problem solving, recognize omissions in their explanations, and provide appropriate feedback. For instance, students who explained their problem-solving steps using Cognitive Tutor demonstrated greater learning for target questions and transfer problems than students who did not use the program and were not required to explain their problem-solving steps (Anderson, Corbett, Koedinger, & Pelletier, 1995; Alevin & Koedinger, 2002; Alevin, Popescu & Koedinger, 2001a; 2001b).

Other computer-based learning environments promote self-explanation through the use of inquiry and metacognitive prompts (Graesser, McNamara, & VanLehn, 2005). In the computer-based program, Point & Query (Graesser, Langston, & Baggett, 1993) students are encouraged to ask questions and form deep causal questions. Students control the question-answering process through hypertext, hypermedia, and other learning environments. Similarly, the computer-based program, Autotutor (Graesser, Lu, Jackson, Mitchell, Ventura, Olney, & Louwerse, 2004; Graesser, Person, & Harter, 2001; Graesser, VanLehn, Rose, Jordan, & Harter, 2001), coaches students to produce explanations by responding to their questions in natural language.

One of the most recent computer-based learning environments to assist students’ acquisition of metacognitive strategies and reading comprehension is iSTART. The iSTART program (Interactive Strategy Trainer for Active Reading and Thinking; McNamara, Levinstein, & Boonthum, 2004; McNamara et al., 2006) is a computer-based learning environment modeled after the face-to-face reading comprehension instructional program SERT. The program is designed to assess the quality of students’ self-explanations, provide them with

elaborative feedback, and promote the use of active reading strategies.

As part of the iSTART program, students observe a simulated classroom, identifying the strategies that simulated learners use to explain the actions of the simulated instructor. They then produce self-explanations under the guidance of the simulated instructor (McNamara et al., 2004). Adolescents using iSTART demonstrated greater learning for science text than their peers who were provided with a demonstration on how to self-explain text (McNamara, et al., 2006). Applications of iSTART confirm that all students benefited from participating in this program, although learning gains vary as a function of students’ prior knowledge. Those with low prior knowledge demonstrate substantial improvement when responding to text-based questions while students with high levels of prior knowledge demonstrate greatest growth when responding to inferential questions (McNamara et al., 2006).

In summary, self-explanation is a versatile, effective strategy that students can use independently or as part of group processing to enhance their learning across a variety of instructional tasks, including the processing of expository texts, mathematical problem solving, and the studying of worked examples. Students from kindergarten through postsecondary school have benefited from instruction in the generation of self-explanations, demonstrating enhanced learning and metacognitive awareness. Learning gains associated with self-explanation are especially powerful for students who possess relatively low levels of prior knowledge for target materials. Instructors, tutors, and peers can effectively encourage students to adopt self-explanation practices with minimal training. Alternatively, computer-based learning environments also hold great promise with respect to enhancing students’ use of this effective learning strategy.

SELF-HANDICAPPING

Self-handicapping refers to the undermining of one's own performance, usually for the sake of impression management (Kolditz & Arkin, 1982). When individuals fear or expect they may fail at tasks that are important to them, they often engage in practices that may actually increase the probability of failure (or at least lower achievement) so they have an excuse, other than lack of ability, for the failure. For example, individuals who value romantic relationships but doubt their ability to sustain one often engage in relationship-destructive behavior (e.g., infidelity, verbal abuse, neglect) so that, when the relationship inevitably fails, they can attribute the failure to their controllable behavior rather than some unchangeable characteristic of themselves. This "shooting-oneself-in-the-foot" can and does appear in any activity or domain, but academic self-handicapping has received a considerable amount of attention because academic achievement reflects on a valued characteristic (i.e., intelligence) and there are frequent opportunities for students to display their abilities, or lack thereof, in public ways. In other words, students often worry that they will appear unintelligent if they perform poorly on a test or assignment, so they sometimes engage in self-handicapping behavior that provides an excuse, other than lack of ability, for the poor performance.

Procrastinating, becoming overly busy with too many activities, placing oneself in a loud or noisy environment to study, getting drunk the night before an important exam, selecting tasks that are much too difficult for one's ability level, failing to study, and failing to get enough sleep are just a few of the many possible self-handicapping behaviors that individuals can engage in. Self-handicapping behavior can range from active (e.g., getting drunk before a test) to passive (failing to study),

but they all have the same effect of potentially undermining performance.

To be considered self-handicapping, the behavior must include several features. First, it must occur before the activity that provides the opportunity for poor performance. Students who simply tell their friends they did not study for the exam after taking the exam are providing an excuse for their potentially low performance, but if they actually did study for the exam they did not self-handicap. Second, many agree that self-handicapping is intentional. Student who do not study because they forgot that there was an exam the next day are not self-handicapping. But purposefully failing to study so that one can have a ready excuse for low performance on the test is self-handicapping. Finally, self-handicapping is a behavior undertaken for the specific purpose of influencing the judgments, or attributions, of others, and possibly oneself. Student who procrastinate until 2:00 a.m. before starting to write their term paper may well perform badly on the paper and may reasonably attribute his or her poor performance to procrastination. But the procrastination behavior would only be considered self-handicapping if the purpose of the procrastination was to provide an excuse for the poor performance, should it occur. Self-handicapping, then, is the intentional, *a priori*, performance-undermining behavior that individuals engage in to create the impression that it is this behavior, and not a lack of ability, that causes the low performance (Berglas & Jones, 1978).

ANTECEDENTS OF SELF HANDICAPPING

Self-handicapping has been conceptualized as a trait-like tendency (Jones & Rhodewalt, 1982) and as a situationally induced behavior (Tice, 1991). Those who have described it as a trait argue that some individuals are simply more inclined to self-handicap than others, and this inclination is present across situations. Sources for the development of such a trait may be biological (i.e., more anxious personality) or can arise from socialization experiences in childhood, such as a strong emphasis on the importance of appearing able. Self-handicapping is also associated with a variety of stable characteristics that may contribute to self-handicapping behavior such as low self-esteem, low perceptions of control, high self-consciousness, and a belief that intelligence is a fixed trait (Berglas, 1985; Rhodewalt, 1994; Knee & Zuckerman, 1998). Researchers who have conceptualized self-handicapping as a situation-specific behavior tend to focus on environmental factors as the sources for the self-handicapping behavior. For example, Midgley and Urdan have examined the association between an emphasis on performance goals in the classroom and self-handicapping behavior (Midgley & Urdan, 2001; Urdan,

Midgley & Anderman, 1998; Urdan, 2004). According to this research, students are more likely to self-handicap in classrooms where they perceive an emphasis on competition and trying to outperform classmates. Similarly, experimental research often creates situations in which participants are told that they will be given a difficult task and that performance on the task is indicative of ability (e.g., Tice, 1991). When individuals can be primed to fear that they may not succeed and that any lack of success may indicate a general lack of ability, self-handicapping is more likely to occur.

Perhaps the strongest experiential predictor of self-handicapping is a history of low achievement. Individuals who perform poorly can develop the expectation of low achievement on similar tasks in the future, especially if they believe the failure is caused by stable and uncontrollable causes, such as a lack of ability. Once individuals develop the belief that they may fail on an upcoming task, they become more likely to engage in self-handicapping behavior, which increases the probability that they will fail again. This cycle of failure→self-handicapping→failure can result in a gradual withdrawal of effort in school (or in any domain), leading to dropping out of the activity altogether (Urden & Midgley, 2003; Zuckerman, Kieffer, & Knee, 1998).

A fair amount of research examining the association between motivation and self-handicapping has revealed that certain motivational characteristics of students and teacher instructional practices are associated with self-handicapping behavior. When students are concerned with not performing worse than other students, and with not appearing academically unable, they are more likely to self-handicap (Kaplan, Middleton, Urden, & Midgley, 2002; Urden, 2004). These concerns, known as *performance-avoidance goals*, can be influenced by teacher behaviors. Teachers who emphasize social comparison and competition in the classroom and publicly display reports of student achievement (e.g., test scores, grades) can promote the adoption of performance-avoidance goals in the classroom (L. Anderman & E. Anderman, 1999). In contrast, Turner and her colleagues found that in classrooms where teachers explicitly supported student autonomy and intrinsic motivation, performance-avoidance goals and self-handicapping were reduced (Turner, Meyer, Midgley, & Patrick, 2003).

CORRELATES AND CONSEQUENCES OF SELF HANDICAPPING

Self-handicapping behavior is associated with lower achievement. Because self-handicapping behavior represents a reduction or withdrawal of effort toward a given task (e.g., not studying for a test), it is not surprising that

self-handicapping is associated with lower performance on these tasks. But there may also be some benefits of self-handicapping. Some research indicates that self-handicappers do feel better about themselves after failure than do students who do not handicap (Drexler, Ahrens & Haaga, 1995; Feick & Rhodewalt, 1997). So there does appear to be some ego-protective function of self-handicapping in failure situations. In addition, there may be benefits for students who are able to succeed despite self-handicapping (Feick & Rhodewalt, 1997). Tice (1991) found that students with low self-esteem were more likely to self-handicap when they feared failing at a task, whereas students with high self-esteem were more likely to handicap when they believed they had a chance to stand out as exceptionally able by succeeding at a task. Some evidence suggests that students who succeed even after engaging in self-handicapping behavior do experience temporary increases in self-esteem. In addition, research indicates that self-handicapping is often successful at helping individuals divert the judgments of others away from low-ability attributions for failure.

Unfortunately, even though self-handicappers are often successful at their attempt to provide excuses other than low ability for their low achievement, they usually do not delude themselves. Self-handicappers describe themselves with words such as “lazy” and “shiftless” (Covington, 1992). Moreover, observers of self-handicappers developed negative attitudes about the personalities and work habits of self-handicappers (Rhodewalt et al., 1995; Smith & Strube, 1991).

PRACTICAL IMPLICATIONS

Because self-handicapping behavior undermines achievement and can lead to long-term withdrawal from achievement activities (such as school), it is important for parents and teachers to discourage self-handicapping and to avoid behaviors that might encourage it. Dweck (1999) and her colleagues have long argued that teachers and parents should promote a view of intelligence as a modifiable characteristic, something that can be improved through effort. They suggest that teachers and parents praise children for using the correct strategies rather than simply telling them how smart they are, as the latter may encourage them to think of ability as fixed, a view that contributes to self-handicapping. Midgley, Urdan, and their colleagues have suggested that teachers should emphasize individual growth, improvement, and understanding of the academic material rather than social comparison and competition, as the latter can make students concerned with appearing able or, more importantly, fearing they might appear stupid. Because it is this fear that leads students to engage in self-handicapping, efforts to reduce this fear will likely result in reduction in self-handicapping as well.

SELF-REGULATED LEARNING

Educators increasingly are emphasizing self-regulated learning as a means of raising students' achievement outcomes. Self-regulated learning (or self-regulation) refers to learning that results from students' self-generated thoughts and behaviors that are oriented systematically toward the attainment of their goals (Zimmerman, 2001). Researchers have identified several self-regulatory processes that students instigate, modify, and sustain, such as attending to instruction, cognitively processing information, rehearsing and relating new learning to prior learning, believing that one is capable of learning, and establishing productive work and social environments. Research shows that increases in self-regulation result in higher student learning and achievement.

BACKGROUND OF SELF REGULATED LEARNING

The emphasis on self-regulated learning in education began as an outgrowth of behaviorally oriented research on self-control in which individuals learned ways to reduce dysfunctional behaviors such as impulsive or disruptive actions. Behavioral researchers (e.g., Mace, Belfiore, & Hutchinson) stress self-regulating processes such as self-monitoring (self-observation and self-recording of one's own behaviors), self-instruction (rules or strategic steps that one applies and often verbalizes during a task), self-evaluation (comparing some aspects of one's behaviors with standards), self-correction (correcting one's behaviors to better match standards), and self-reinforcement (rewarding oneself with reinforcers such as points or free time when behaviors meet or exceed standards).

An issue with behavioral theories is that because they do not consider learners' internal states such as thoughts, beliefs, and emotions, they offer incomplete explanations

of learning. Against this backdrop cognitive theories of learning began their ascendance in the 1960s and soon became the dominant focus of human learning. But researchers often found that cognitive skills and abilities did not fully account for students' learning, which suggested that other factors such as motivation and self-regulation were important (Zimmerman, 2001). These findings led to the emergence of cognitive theories of self-regulated learning.

THEORIES OF SELF REGULATED LEARNING

Cognitive theories of self-regulated learning differ in many ways but share some common features (Zimmerman, 2001). One common feature is an emphasis on learners being proactive and exerting control on their learning processes and environments. Self-regulated learners do not passively take in information but rather proactively develop their skills and strategies. Cognitive theories also assume that self-regulated learning is a cyclical process in which learners set goals, implement strategies, monitor their learning progress, and modify their strategies when they believe they are not effective. A third common feature is an emphasis on motivation. Self-regulated learning does not occur automatically; rather, students approach learning with goals and the extent to which they self-regulate depends on motivational factors such as their commitment to their goals, their beliefs about the likely outcomes of their actions, and their self-efficacy, or personal beliefs about their capabilities to learn or perform actions at designated levels.

Although there are various cognitive self-regulated learning theories, three that have been applied extensively to school learning are information processing, social constructivist, and social cognitive theories. Information processing theory stresses cognitive functions such as attending to, perceiving, storing, and transforming information. For example, Winne and Hadwin postulated that self-regulated learning comprises four phases: defining the task, setting goals and planning how to reach them, enacting tactics, and adapting metacognition. Initially learners process information about the conditions that characterize the task to clearly define it. Sources of information include task conditions (task information that learners interpret based on the environment such as a teacher's directions) and cognitive conditions that learners retrieve from long-term memory such as how they did on prior tasks and motivational information (e.g., perceived competence). In the second phase learners set a goal and a plan for attaining it to include the learning strategies they will use. During the third phase learners apply their strategies, and in the fourth phase they adapt their plans and strategies based on self-

evaluations of their success (this phase is optional if no adaptation is needed).

Within each phase, cognitive information processing constructs new information or information products. Information processing works on existing information and includes processes characterized by the acronym SMART: searching, monitoring, assembling, rehearsing, and translating. While working on a task, students fill in slots in a script that includes conditions, operations, products, evaluations, and standards. Information processing outcomes are judged against standards and these evaluations (e.g., progress is on target or too low) are used to bring new conditions to bear on students' learning activities.

Vygotsky's theory of development provides a social constructivist account of self-regulation. Lev Vygotsky (1896–1934) believed that people and their cultural environments constitute an interacting social system. Through their communications and actions people in children's environments teach children tools (e.g., language, symbols) needed for developing competence. By using these tools within the social system, learners develop higher-level cognitive functions such as problem solving and self-regulation. Self-regulated learning includes the coordination of such mental processes as memory, planning, synthesis, and evaluation. These coordinated processes do not operate independently of the context in which they are formed. A student's self-regulated learning processes reflect those that are valued and taught in the culture of the student's home and school.

Vygotsky believed that people learn to self-regulate through control of their own actions. The primary mechanisms affecting self-regulation are language and the zone of proximal development (ZPD), or the amount of learning possible by a student given the proper instructional conditions. Initially children's actions are directed by the language (speech) of others but children gradually internalize this self-directing language and use it to self-regulate. Through interactions with adults in the ZPD children make the transition from behaviors regulated by others to behaviors regulated by themselves, or self-regulated learning.

Bandura's social cognitive theory posits that human functioning results from reciprocal interactions among personal factors (e.g., cognitions, emotions), behaviors, and environmental conditions. Self-regulated learning fits well with this idea of reciprocal interactions because personal factors, behaviors, and environmental conditions change during learning and must be monitored. Such self-monitoring can lead to additional changes in students' strategies, cognitions, affects, and behaviors.

This process is reflected in Zimmerman's 2000 three-phase self-regulated learning model comprising forethought, performance/volitional control, and self-

reflection. The forethought phase precedes performance and refers to processes that set the stage for action. The performance/volitional control phase includes processes that occur during learning and that affect motivation and action. During the self-reflection phase, learners mentally review their performances and determine whether changes in behaviors or strategies are needed.

Various self-regulatory components come into play during the different phases. Two processes active throughout the model are goals and self-efficacy. In the forethought phase, learners set goals and hold a sense of self-efficacy for attaining them. During the performance phase they implement learning strategies and cognitively compare their performances with their goals to determine progress. Their self-efficacy is sustained when they believe that they are making goal progress. During self-reflection learners determine whether their present strategy is effective. If they feel self-efficacious for succeeding but believe that their present strategy is not working well enough, they may alter their strategy such as by working harder, persisting longer, deciding to use a different method, or seeking help from others. These self-regulatory processes promote learning, motivation, and self-efficacy.

DEVELOPMENT OF SELF REGULATED LEARNING

The self-regulated learning processes discussed in the preceding section do not appear automatically in learners. Rather, students become more proficient self-regulators as a function of cognitive development and learning.

The development of self-regulation depends heavily on the use of self-regulatory or private speech (speech that is non-socially communicative). According to Kopp, increasing self-regulation involves a transition from responding to the commands of others to the use of speech and other cognitive tools to plan, monitor, and direct one's activities. Young children's actions are directed by adults. The meaning of actions depends on both the context and the tools (e.g., language, symbols) used to describe the actions. Through interactions with adults in the ZPD, children make the transition from behaviors regulated by others to behaviors regulated by themselves. This transition occurs as children develop the capability for using private speech to direct their actions. Such speech which often may be talking aloud eventually becomes internalized. The internalization of self-regulatory speech does not imply the absence of adult influence. Children's private speech may heavily reflect the directive speech of key adults (e.g., parents, teachers).

Research has identified other developmental changes. Zimmerman and Martinez-Pons found that between grades five and eight children increase their use of planning, sequencing, and goal-setting. Academic studying also

undergoes changes. Meece noted that younger children equate studying with rereading material, whereas older students make greater use of note taking and underlining. Younger children also are less capable of monitoring their comprehension. Older children are better able to determine inconsistencies in text and when they find them they act to resolve them such as by rereading the passage to ensure that they read it accurately or by reading the broader passage to better determine the context.

Thus, improvements in self-regulated learning involve cognitive development and learning. As children become older they are better able to cognitively engage in such self-regulatory activities as planning, goal setting, monitoring comprehension, evaluating progress, and adjusting strategies as needed. But teaching also is important because students can learn to be better self-regulators, as discussed below.

RESEARCH ON IMPROVING SELF REGULATION SKILLS

As discussed by Schunk and Ertmer, much educational research shows that children, adolescents, and adults can be taught self-regulated learning skills, that their use of these skills improves learning, and that skills can maintain themselves over time and generalize to new learning settings. For example, teaching students to use goal setting can improve their self-regulated learning. There are different distinctions among goals, but one is between a process goal (what skill or strategy students are attempting to learn) and an outcome goal (the intended performance). In algebra a student may be trying to learn how to use the binomial theorem (process goal) or trying to finish a problem set (outcome goal). Researchers have found that focusing students' attention on process goals especially in the early stages of learning improves self-regulated learning better than focusing on outcome goals. However, Zimmerman and Kitsantas found benefits from shifting from process to outcome goals. High school students were taught a writing revision strategy. Students received a process goal (following steps in the strategy), an outcome goal (number of words in sentences), or initially a process goal but then were advised to shift to an outcome goal. Learners who changed goals as their revision skills developed demonstrated higher self-efficacy and skill than students who pursued either the process or the outcome goal.

Self-monitoring and perceptions of progress are key self-regulated learning processes. Researchers have found that students can be taught self-monitoring skills and that giving them feedback on their learning progress improves their use of self-regulatory skills. Schunk and Swartz found that providing students with a process goal of learning to use a writing strategy and feedback that linked strategy use

with improved writing performance led to the highest use of a writing strategy and that this strategy usage maintained itself over time and generalized to writing tasks on which students had received no instruction.

Self-evaluations of progress help students focus on self-regulation processes and can raise their motivation and self-efficacy for continuing to improve. Research shows that allowing students to periodically evaluate their learning capabilities raises their self-efficacy, motivation to self-regulate, and use of self-regulated learning strategies. A particularly effective approach is to give students a learning process goal (e.g., learn to use a strategy to solve problems) and allow them to self-evaluate their capabilities for using the strategy successfully.

There are formal programs designed to improve students' self-regulation skills. Weinstein, Husman, and Dierking described a university course in strategic learning that teaches students to use several steps in working on academic material: set a goal, reflect on the task and one's personal resources, develop a plan, select potential strategies, implement strategies, monitor and evaluate the strategies and one's progress, modify strategies as needed, and evaluate the outcomes to determine if this approach should continue to be used. Prior to the course students complete the Learning and Study Strategies Inventory, and instructors use this information to help students improve their skills, motivation, self-regulation, and academic environment.

EDUCATIONAL IMPLICATIONS

The preceding research makes clear the connection between effective self-regulation and gains in students' learning and achievement. Research findings also suggest ways to help students improve their self-regulated learning skills.

One suggestion is that, although students may discover effective self-regulated learning strategies on their own, they benefit from sound instruction and models that explain and demonstrate strategies. This does not imply that strategy instruction programs must be formally structured, but some guidance to students is important especially in the early stages of learning. As students become more proficient they are better able to construct effective strategies on their own and, as Zimmerman and Kitsantas found, pursue outcome rather than learning process goals.

A second point is that self-regulation should be taught in conjunction with an academic subject and not separately. Students benefit from seeing how they can use what they learn. Many self-regulation strategies are generic and can be applied to different content, but their implementation typically will vary depending on the content area. Thus, self-monitoring is a general strategy but what students self-monitor will vary depending

whether they are reading passages in text, writing essays, or solving problems in geometry. When general strategies are taught it is important also to show students how the strategy can be adapted for use with other content.

Students should be taught how to evaluate their learning progress and given opportunities to do so. Typically in school students have their learning evaluated for them by teachers. But self-regulation is a cyclical process in which students self-regulate, check their progress, and adjust their approach as needed. Students need opportunities for self-evaluation because they may not do it automatically and it affects their motivation and self-regulated learning.

Developmental factors must be taken into account in teaching students to be better self-regulated learners. Self-monitoring is best kept simple for young children, such as by having them use a check list or count how many problems they have completed. With development, students can implement more elaborate self-regulation strategies; however, they are apt to benefit from instruction showing how to evaluate progress in areas where progress may be difficult to assess, such as writing improvement or reading comprehension.

Motivational variables also should be included in self-regulation programs. Developing effective self-regulation strategies takes time and effort, and students may not be motivated to self-regulate unless they see benefits compared with their usual approaches. They also may not feel self-efficacious about improving their self-regulation. Providing students with progress feedback linking strategy use with improved performance can raise their self-efficacy and motivation and enhance their self-evaluations of progress.

School learning typically is focused on academic content. Self-regulated learning skills do not develop automatically, but these skills will benefit students for life-long learning. Therefore, it behooves teachers and parents to help students develop their self-regulatory competencies and encourage them to practice using them in all facets of their lives.

SENSATION-SEEKING

Sensation-seeking is characterized by researchers as a basic human need and as a component of human personality. The need for sensation runs along a continuum, wherein some individuals have a high need for sensation, whereas others have a low need for sensation. An individual who has a high need for sensation seeks sensation in the form of novelty, complexity, or physical stimulation from the environment (Zuckerman, 1979, 1988). Some researchers argue that sensation-seeking includes the willingness to actually take risks, whereas others argue that the willingness to take risks is a separate but related construct (e.g., Arnett, 1994).

The concept of sensation-seeking primarily has been studied in the domains of clinical psychology, personality

psychology, health psychology, and communications. From an evolutionary perspective, attention to novel stimuli in the environment was necessary for human survival. Specifically, the detection of new stimuli alerted humans to potential dangers (Franklin, Donohew, Dhoundiyal, & Cook, 1988). For example, an awareness of new sounds in the environment could alert an individual to the approach of a potential predator. Most researchers in the early 2000s view sensation-seeking as an important personality trait of humans, albeit not one that is necessary for survival. The fact that sensation-seeking is viewed as a personality variable is important because personality variables are often not easily malleable; thus an individual who expresses a high need for sensation is unlikely to change much over time.

Research from the field of communications generally indicates that individuals with a high need for sensation are more likely to attune to and pay attention to messages (i.e., communications from teachers, messages from television commercials, etc.), when such messages or communications are presented in ways that catch and hold the attention of the individual.

THE IMPORTANCE OF SENSATION SEEKING

Much of the research on sensation-seeking that is relevant to education and to educational psychology emanates from the field of health communications. In addition, much of this work has been applied research, often in school settings, and often with adolescent populations. Specifically, communication researchers have found that individuals pay attention to messages (e.g., media messages such as radio or television advertisements) based on (a) the individuals' need for sensation and (b) the level of sensation or stimulation that is provided by a given message. A media message that provides high levels of sensation is typically loud, colorful, and filled with motion and action. Intervention studies have found that when the sensation-value of a message is increased (i.e., it is made to be more stimulating by making it loud, including more colors and motion, etc.), the message is more attractive to individuals with a high need for sensation and thus has more effect on individuals' subsequent attitudes and behaviors (Donohew, Lorch, & Palmgreen, 1998).

Individuals who have high sensation needs typically engage in certain predictable behaviors. Most notably, the research indicates that individuals who exhibit a high need for sensation often are more likely to engage in risky or dangerous behaviors, such as abusing substances and having unprotected sexual intercourse (Baer, 2002; Donohew, Zimmerman, Novak, Feist-Price, & Cupp, 2000). However, research also indicates that high-sensation seekers exhibit other diverse characteristics. For example, one

study found that these individuals report greater use of the Internet than do individuals with lower reported levels of sensation-seeking (Lin & Tsai, 2002).

Research indicates that sensation-seeking rises markedly during early adolescence (Donohew et al., 1994). For many adolescents, this increase coincides with the transition from elementary school into middle school. Thus although students with high needs for sensation are present in elementary, middle, and high schools, these students may be particularly prevalent in middle school settings.

SENSATION SEEKING IN THE CLASSROOM

Students with high need for sensation are likely to display certain predictable characteristics. First, these students may engage in risky activities in school, such as running in the hallway, jumping off desks, throwing food in the cafeteria, or more serious activities such as using illicit substances or getting into physical fights. Second, these students may be particularly attracted to stimulating experiences in school; such students may want to listen to loud music or to look at highly visually stimulating materials (e.g., colorful books with many bright pictures). Third, these students are likely to get bored easily; they may not fare well in classrooms in which they are required to sit for long periods of time and listen to lectures.

Nevertheless, these students still pay attention to tasks, activities, and media messages that are low in sensation-value, if the topic is particularly salient to them. For example, individuals may attend to a seemingly boring documentary on cancer research, if they have close relatives or friends who is suffering from the disease; they may attend to a lecture on the stock market if they have just received the gift of a larger sum of money.

SUGGESTIONS FOR EDUCATORS

Scholars who study sensation-seeking have examined in particular how media (e.g., television programs or commercials) and general communication in the classroom (e.g., the ways that teachers communicate information to students) affect learning. Students with a high sensation needs benefit from instructional practices that meet those needs. It certainly is not possible to meet the needs of these students at all times, but some lessons can be altered to better hold their attention. Clear suggestions for educators emerge from this literature.

First, these students are more academically engaged in classrooms in which novel, unpredictable activities occur. These students get bored easily in monotonous settings in which activities are repeated daily. Thus, these students benefit from changes in daily routines and the presentation of new instructional materials from time to time (e.g., the use of new texts, the introduction of novel

activities, the use of videos and the Internet, holding class outside on a nice day).

Second, educators can adapt curricular materials and classroom activities to make them more appealing to students who have high sensation needs. Whereas these adaptations benefit the high sensation-seeking students, they also may be interesting and novel for students who do not have such high needs. Researchers have identified specific ways in which curricula can be adapted for students with high sensation needs. These adaptations include: (a) the use of dramatic role-playing activities (including the videotaping of such activities), (b) the incorporation of videos and music into traditional lessons, (c) the inclusion of outside speakers with real-world experiences, and (d) the opportunity for students to facilitate conversations and activities in the classrooms (Anderman, Noar, Zimmerman, & Donohew, 2004).

Donohew and his colleagues have identified the characteristics of academic tasks and media messages that are likely to be attractive to adolescents with a high sensation needs (Donohew et al., 1998). These include: (a) tasks that are novel or unusual, (b) tasks that are complex, (c) tasks that provide auditory and visual stimulation, (d) tasks that are unconventional, (e) tasks that are fast-paced, (f) tasks that are complex or ambiguous, and (g) tasks that are suspenseful.

Third, educators need to be aware that students with high sensation needs may also experience problems with behavior in the classroom. These students are more likely to get out of their seats, to talk to their neighbors, and to seek attention from the teacher. Thus targeting students with high needs for sensation early on and setting up classroom contexts to provide for these students' needs may alleviate some potential behavioral problems in the classroom.

Finally, although most of the research has focused on students who exhibit high needs for sensation, educators must be aware of students who have a low need for sensation as well. Although research suggests that tasks that are low in sensation value appeal to students with a low need for sensation (Zuckerman, 1988), it is incorrect to assume that all academic tasks or media messages that are low in sensation-value will always be attractive to these individuals. Donohew and others suggest that these messages may simply be boring and ineffective for all learners. However, educators also must be aware that students with low needs for sensation may find tasks that are high in sensation value particularly over-stimulating.

SERVICE-LEARNING

Students and faculty are engaged in service-learning at every level of the educational ecology; state and international communities, K-12 schools, and colleges and universities in the United States and abroad. The National Center for Education Statistics (NCES) estimates that more than 13 million K-12 students participated in service and service-learning during the 2000-2001 academic year (Fiske, 2001). During the 2005-2006 academic year more than 6 million college and university students attending more than 1,000 institutions of higher education also were engaged in some type of service-learning (Campus Compact, 2007). These data suggest that service-learning is a comprehensive and innovative pedagogy in college, universities, and K-12 schools.

DEFINITION

In the early 2000s, service-learning projects continue to grow and evolve in schools and institutions of higher education in such a way that a common definition has not yet emerged; however, a number of accepted definitions for service-learning are used by researchers and practitioners. One definition proposed by Campus Compact (2001) focuses on service-learning as pedagogy: "service learning is an educational methodology which combines

community service with academic learning objectives, preparation for community work and deliberate reflection” (p. v.). A second definition offered by Campus Compact states: “service-learning means a method under which students learn and develop through thoughtfully organized service that is conducted in and meets the needs of a community and is coordinated with an institution of higher education (or K-12 school), and with the community; helps foster civic responsibility; is integrated into and enhances the academic curriculum of the students enrolled; and include structured time for students to reflect on the service experience” (p. 15). Tom Ehrlich of the Carnegie Foundation for the Advancement of Teaching defines services learning as follows: “the various pedagogies that link community service and academic study so that each strengthens the other. The basic theory of service learning is Dewey’s: the interaction of knowledge and skills with experience is key to learning” (1996). Researchers Robert Bringle and Julie Hatcher (1995) define service-learning as “a credit-bearing, educational experience in which students participate in an organized service activity that meets identified community needs and reflect on the service activity in such a way as to gain further understanding of course content, a broader appreciation of the discipline, and an enhanced sense of civic responsibility.”

Staff at Learn and Serve America offer a core concept of service-learning, which holds wide agreement among both researchers and practitioners: “service learning combines service objectives with learning objectives with the intent that the activity change both the recipient and the provider of the service. This is accomplished by combining service tasks with structured opportunities that link the task to self-reflection, self-discovery, and the acquisition and comprehension of values, skills, and knowledge content” (retrieved from <http://www.servicelearning.org>, on April 15, 2008).

The National Commission on Service-Learning (Fiske, 2001) suggests that service-learning is a teaching and learning approach that integrates community service with academic study to enrich learning, teach civic responsibility, and strengthen communities. The intentional and planned link to the curriculum is the hallmark of service-learning. A second distinction is the reciprocal nature of the partnership between campus and community in the identification of the need and in the benefits resulting from the partnership. In other words, service-learning activities provide a mechanism for active learning and the construction of authentic learning experiences. It allows students to translate and reflect on their experience and to work in teams with other students and community members who may be different from themselves toward solving authentic problems in the community. Service-learning projects are group projects that prepare students for membership in teams in schools and

future professions. Finally, service-learning projects provide faculty with a strategy for moving away from the role of lecturer to the role of a facilitator and guide who facilitates the incorporation of new knowledge with old and the application of information to authentic, new, and varied contexts or persons.

One challenge in the implementation of service-learning activities is the misconception that these are equivalent to other community-based activities such as experiential education, volunteerism, internships, practica, and field experience. Furco (1996) provides a conceptual model for differentiating service-learning from other forms of experiential education that uses two factors: the intended beneficiary and the overall balance between service and learning as the discriminating variables. For example, volunteerism may be defined as an experience in which students provide a service and the intended beneficiary is the community partner. Community service is the engagement of students in activities with a primary focus on the service provided and the benefits accrued for the community partner. Students may acquire some benefit, but it is not necessarily tied to their discipline. At the other end of the continuum, internships engage students in service activities with the purpose of providing hands-on learning opportunities to enhance the learning and application of a set of skills or knowledge: The focus is the student.

Field experiences provide students with the opportunity to perform a service as part of a program designed primarily to enhance the understanding of a field of study: The emphasis is on the student’s acquisition of skills within the field of study. Service-learning is distinguished from these other forms of experiential education by the intention to benefit the student and the community in a reciprocal and equal partnership. The focus is equally divided between the service provided and the learning that occurs. Weigert (1998) identifies six elements of service-learning that further differentiate it from other community-based outreach activities: (1) the service is meaningful to the community; (2) the service meets a need or goal; (3) the service is defined and identified by the community; (4) the service is embedded in course objectives; (5) assignments which require reflection are used to link service with objectives; and (6) the assignment has value and is assessed and evaluated.

THEORETICAL MODEL AND IMPLEMENTATION

The conceptual model that has guided service-learning was proposed by David Kolb (1984) and was built on the process of experiential inquiry proposed by John Dewey. The six step process of inquiry (encountering a problem; proposing a problem or question to be answered; gathering

information to answer the question or solve the problem; making hypotheses; testing hypotheses; and making judgments or assertions) was used by Kolb to develop a learning cycle that included four phases: concrete experiences, reflective observations, abstract conceptualization (with faculty mentoring and guidance), and active experimentation. These phases are cyclical and generative.

Billig (2006) provides eight principles of effective practice in the development of service-learning activities within the curriculum: (1) service must be integrated in the curriculum; (2) diverse perspectives and experiences foster civic discourse and democratic values for all participants, both student and community partners; (3) the service is meaningful, requiring problem-solving and critical thinking; (4) reflection is used to encourage critical and creative thinking; (5) students contribute ideas in each phase of the experience; (6) the process is monitored by knowledgeable faculty and staff; (7) the experience is of sufficient intensity and duration; and (8) partnership is reciprocal and collaborative.

Faculty implementing service-learning generally move through four stages. First, community needs are identified and defined by community and campus partners, goals are then set for both learning and service. Faculty and community partners clearly delineate responsibilities and expectations and typically provide some type of orientation for students and staff if needed. The service experience constitutes the second phase and provides authentic and meaningful experience linked to the discipline and course objectives. Reflection is phase three and may occur in multiple ways: by analyzing concepts, evaluating experiences, posing questions, and reflecting on the problem/need and potential solutions. Evaluation and celebration is the final stage and recognizes the work of the student and community partner and provides a public mechanism to share the accomplishments of the students and community partners in meeting the need and/or solving the problem.

IMPACT

A number of large and small sample studies have demonstrated the positive impact of service-learning on personal outcomes, such as efficacy, identity, spiritual growth, and moral development (Astin & Sax, 1998; Eyler & Giles, 1999), the ability to work with others, leadership, and communication skills (Driscoll, Holland, Gelmon, & Kerrigan, 1996). Social outcomes such as the reduction of stereotypes, facilitation of cultural and racial understanding, sense of social responsibility, and citizenship skills (Eyler & Giles, 1999) have also been positively impacted (Bringle & Kremer, 1993). Participation in service-learning has also been documented to affect community involvement and volunteerism after graduation (Astin, Sax, & Avalos, 1999).

Faculty report that service-learning has a positive impact on academic learning and improves students' ability to apply what they have learned in the real world (Driscoll et al., 1996; Eyler & Giles, 1999). For example, a study of California high school students found that those students who participated in service-learning scored higher on all of the study's academic measures than those students enrolled in the comparison group who did not participate (Furco, 2002). These findings have been replicated in Philadelphia, Denver, and Hawaii (Billig, 2006). A study of fifth graders in Michigan also found that participation in service-learning activities was positively correlated with state test scores (Klute & Billig, 2002). Similar findings are reported for sixth grade students in Philadelphia (Billig, 2006). Participation in service-learning has been associated with higher attendance rates (Shumer, 1994) and decreased referral for disciplinary reasons (Follman, 1998). Service-learning also contributes to career development (Astin & Sax, 1998) and to students' greater sense of belonging and identification with their school (Eyler & Giles, 1999). Most importantly, students who are engaged in service-learning are more likely to graduate (Astin & Sax, 1998).

As of 2008, increased attention to service-learning was occurring concurrently with a focus on engaged teaching and learning. Researchers, scholars, and professional organizations have encouraged U.S. schools, colleges, and universities to focus on student learning and academic outcomes. Faculty state that their involvement in service-learning is motivated by one of three philosophical questions. First, is the value of service-learning for enhancing academic and interdisciplinary learning? If so, this philosophy would also support service-learning as a methodology that allows students to deepen their understanding of their discipline while developing strategies of inquiry appropriate across all disciplines and life experience. Second, is the use of service-learning for the acquisition of the skills and behaviors of leadership? Knowledge of and skills necessary for effective leadership are best experienced and gained firsthand in the real world. Third, is the service-learning conducive to civic engagement? This connection is frequently explored in published research.

In summary, service-learning has been demonstrated to benefit all members of the partnership: students, faculty, and community. Students have the opportunity to apply knowledge in meaningful ways, to work in interdisciplinary partnership with students from other disciplines and communities, and to acquire and/or change disposition and lifelong behaviors and attitudes. Community partners are able to meet an identified goal and establish positive relationships with students and the sponsoring institution. Faculty have the opportunity to support the expansion of student knowledge in application and applied settings; to

demonstrate or model the application of discipline specific knowledge in applied settings; to establish partners in the application of research, and to respond to the needs identified by community partners for engaged research. Schools and other educational institutions are able to make connections to the community and form trusting and authentic partnerships with community members and organizations in engaged research and service.

RESOURCES

After the devastation of Katrina and other hurricanes in the Gulf Coast region of the United States, student organizations and faculties across the country responded through service-learning and other community outreach and engagement efforts. Student groups organized efforts to provide books, school supplies, clothing, and other necessities. Campuses offered displaced students and faculty places to live, tuition waivers, and opportunities to complete degrees that would have otherwise been abandoned. In 2005 the U. S. Housing and Urban Development and the Corporation for National and Community Service funded the Gulf Coast Universities Rebuilding America Partnership in response to the needs of communities affected by the hurricanes. This program provides an organized mechanism for supporting and engaging college and university students, faculty, and staff in helping rebuild the Gulf Coast region (for more information, see <http://www.learnandserve.org/about/programs/index.asp>).

Serve America (the predecessor of Learn and Serve America) was created in 1990 through funding by the National and Community Service Act (As amended through December 17, 1999, 170, P.L. 106 170) and the Domestic Volunteer Service Act (as amended by Public Law 106 170, approved December 17, 1999) to integrate community service with curricula through service-learning. In 1993 President Clinton signed legislation to create the Corporation for National and Community Service whose mission is to improve lives of Americans, strengthen communities, and foster civic engagement through service and volunteering. The corporation provides opportunities for more than two million Americans of all ages and backgrounds to serve their communities and country through Senior Corps, AmeriCorps, and Learn and Serve America, which provides support to K-12 schools, institutions of higher education, and community groups. The mission of Learn and Serve America is to facilitate service-learning projects by providing grant support for school-community partnerships, technical support and training, and the collection and dissemination of information about model programs, curricula, and research (for more information, see <http://www.learnandserve.org>).

Campus Compact, which is funded by a number of public and private sources (i.e., Corporation for National

and Community Service, Ford Foundation, Andrew Mellon Foundation, Pew Charitable Trusts, and the Carnegie Corporation of New York), began in 1985 as a collaboration of the presidents of Brown, Georgetown, and Stanford universities in cooperation with the Education Commission of the States. These university presidents believed that students on their campuses were socially and politically responsive to the needs of their communities and neighbors and were actively involved in community service. They sought a mechanism to document these efforts and to encourage supportive structures to increase the participation of other students. By 1991 the Compact had funded more than 120 grants and 130 service-learning workshops across the nation to faculty who linked community serve with the academic mission of higher education, and in 1999, a total of 51 college and university presidents crafted the Presidents' Declaration on the Civic Responsibility of Higher Education. By 2003, one-fourth of all higher education institutions in the United States were members of Campus Compact. These members promote civic engagement through shared knowledge and resources in the provision of service-learning efforts in the areas of literacy, health care, hunger, homelessness, the environment, and senior services. The Campus Compact mission is "to advance the public purposes of colleges and universities by deepening their ability to improve community life and to educate students for civic and social responsibility" (retrieved April 15, 2008, from www.compact.org).

Students at Campus Compact's more than 1,000 member colleges and universities contributed an estimated \$7.1 billion in services to their communities during the 2005 2006 academic year. Nearly one-third of students participated in volunteer and service-learning work coordinated by campuses, performing an average of 5.6 hours of work each week, for a total of 377 million hours of service. It is important to note that these figures represent only work organized or supported by member colleges and universities; it does not capture other student volunteer work. The most common service programs on member campuses focused on tutoring and mentoring, a reflection of the high number of member institutions that have partnerships with local K-12 schools and other youth-serving organizations. Other commonly addressed issues included poverty, reading/writing, housing/homelessness, hunger, the environment, health care, multi-cultural issues, and services to seniors (Campus Compact, 2007).

Katherine M. McCormick

SEXUAL ORIENTATION

While commonly considered a way to divide the world into dichotomous and unambiguous categories of heterosexual/homosexual or gay/straight, sexual orientation is, in reality, a complex configuration of sexual attraction/desire, sexual behavior, and sexual identity. For many individuals, these three aspects of sexual orientation are neither neatly aligned nor stable across the lifespan. For example, a young adolescent female may only engage in sexual intercourse with her boyfriend, may experience sexual/romantic attractions to both males and females, live in a heterosexual marriage for a number of years during early adulthood, and claim a lesbian or bisexual identity in mid-adulthood. Likewise, a young male may be aware from an early age that his attraction is oriented to other males; he may engage in insertive-only sexual behaviors with other male sex partners, and he may claim a heterosexual identity throughout adulthood. Therefore, those who identify as gay, lesbian, or bisexual (GLB) or even heterosexual, do not form distinct, homogenous groups. Each of the three aspects of sexual orientation exist on a continuum, with fewer individuals endorsing exclusive attraction or behavior toward one sex, and with many other individuals endorsing some level of attraction to or behavior toward each sex.

Even this generally accepted tripartite conceptualization of sexual orientation vastly oversimplifies the human experience of sexuality. By focusing on the anatomy of the chosen sex partner(s) as the determining factor of sexual identity, the understanding of the complexities of sexuality and how it develops within the social context of family, peers, schools, and communities is truncated. Acknowledging this oversimplification of a complex phenomenon, the remainder of this article focuses on youth who are (or who are perceived to be) same-sex attracted.

Given this necessarily limited scope, readers are urged to consult other resources on transgender youth, another distinct and non-homogenous social identity. Transgender individuals represent the *T* in the common acronym GLBT (gay, lesbian, bisexual, transgender). However, transgender identities are constructed around the experience of the self as male or female rather than one's sexual orientation toward other persons perceived as male or female. That is, a transgender person may identify as either male or female (in contrast to the perceived and assigned sex) and then separately as heterosexual, homosexual, or bisexual depending on the perceived/assigned sex of those to whom the person is sexually attracted. Transgender youth share with GLB youth the experience of having to negotiate a stigmatized identity in often hostile or rejecting environments. However, their experiences and needs cannot be assumed to be the same. Further information and focused discussion of

the important and unique needs of transgender youth in schools can be found in most of the resources suggested at the end of this entry.

As with other socially constructed categories (e.g. race, ethnicity, sex, age), sexual orientation categories reinforce power hierarchies within the culture. Heterosexual identities are privileged and non-heterosexual identities are invisible or even oppressed. For example, displays of heterosexuality in the form of social dating opportunities, proms, homecoming kings and queens, are “embellished, protected, and promoted” in schools (Leck, 2000, p. 344). In stark contrast, several states have passed legislation forbidding positive representations of homosexuality in schools (Kosciw & Diaz, 2006).

The realities of heterosexism and homophobia are the social context in which sexual minorities (the term commonly used to refer to all of those who are perceived to be or who claim to be non-heterosexual) develop their identities. In response to heterosexist and/or homophobic social contexts and social interactions, sexual minority adolescents and adults frequently conceal their same-sex sexuality (even on confidential research surveys), making it impossible to know with certainty the distribution of sexual minority identities in the general population. Additionally, for other individuals, the available categorical labels for those who experience same-sex attractions do not adequately describe their experience and thus they chose not to check a box on surveys or in their self-referent discourse (Diamond, 2005; 2006). With these caveats in mind, the best and most recent (as of 2007) population studies have determined that approximately 2 to 4 percent of the general population has a homosexual orientation (Laumann, Gagnon, Michael, & Michaels, 1994). In real numbers, this statistic implies that in a high school of 1,000 students, approximately 20 to 40 individuals will, by adulthood, identify as gay, lesbian, or bisexual. While a relatively small percentage of youth in any one school may identify as GLB, exponentially more heterosexually identified youth have at least one GLB parent, sibling, or other close family member.

School communities, thus, are filled with students, teachers, and staff who either are non-heterosexual themselves or have a close affiliation (friend or family member) to someone with a non-heterosexual identity. Public education that promotes democratic values and produces an informed citizenry that will positively contribute to a diverse, global society requires multicultural (rather than monocultural) competence that includes accurate information about and respectful interaction with sexual minorities. The respectful, professional, and inclusive treatment of sexual minority teachers, school personnel, and students provides a powerful opportunity for increasing multicultural competence among all. The absence of strong mod-

eling of this kind of inclusivity perpetuates heterosexism and is detrimental to the goals of social justice and democracy. Having now emphasized that school communities include GLB teachers, GLB staff, GLB students, children of GLB parents, and family members of GLB individuals, the remainder of this article focuses on the needs of GLB youth in the school context.

NORMATIVE DEVELOPMENT OF SEXUAL MINORITY YOUTH

Like all adolescents, sexual minority youth face the developmental task of consolidating their identities within the context of their families, peers, and communities. That is, like heterosexual youth, sexual minority youth are trying to answer the question of who they are in relation to others and the world around them. To the extent that youths live in a social context that is characterized by homophobic attitudes and the heterosexist assumption that all so-called normal youth are heterosexual, sexual minority youths must weigh the risks of disclosing their sexual orientation. Conforming feminine or masculine appearance may make concealment a realistic option for some sexual minority youths. In any case, the on-going decisions to disclose or conceal one’s identity from various people in the social network (e.g., family members, friends, teachers, and other adults) can be a significant source of chronic stress for some youths, particularly for those from racial/ethnic groups, religious groups, families, schools and/or communities that are intolerant of same-sex sexuality. Such adolescents may remain closeted rather than risk the loss of family and/or community support. In some cases, disclosure could result in the threat of violence and/or homelessness. Overall, however, same-sex attracted youths (particularly boys) are acknowledging same-sex attraction, questioning their sexual orientation and/or coming out at younger ages than in past generations (D’Augelli, 2005), perhaps due to increasing visibility of sexual minority individuals and families in the media and in many communities.

Regardless of the decision to disclose or conceal same-sex attraction, this milestone is considered the beginning of the coming out process for sexual minority youth. While identity models have portrayed a linear, lock-step process of gay and lesbian identity development that begins with acknowledgment and acceptance of one’s same-sex sexuality and ends with claiming a stable identity and disclosing it to others, the actual experiences of this process have been demonstrated (most notably in young women) to be rarely this simple, tidy, and final (Diamond, 2005; 2006). Some youths altogether reject sexual identity labels and categories and others identify as *queer* rather than gay, lesbian, or bisexual as a way to reclaim or reframe a derogatory label as one of power and pride.

RISK AND PROTECTIVE FACTORS

As noted above, sexual minority youths face chronic stressors that are typically not a part of heterosexual youths' life experience. These chronic stressors, referred to collectively as "minority stress" (Meyer, 2003) include experiences of discrimination and prejudice, anticipation of rejection, internalized homophobia (i.e., negative attitudes and feelings incorporated into the self-image), and, as mentioned above, disclosing or concealing one's identity in various social contexts and relationships. Perhaps the most pervasive and destructive minority stressor frequently experienced by GLBT students in schools is peer harassment, bullying, and violence (Russell, Franz & Driscoll, 2001; Human Rights Watch, 2001; Udry & Chantala, 2002). A 2005 national survey of sexual minority youths' perceptions and experiences of their school climate found that two out of three students had been verbally harassed because of their perceived sexual orientation. Half of the participants had been verbally harassed because of the way they expressed their gender. A full three out of four participants felt unsafe at school because of treatment they received because of one personal characteristic, usually sexual orientation or gender expression (Kosciw & Diaz, 2006).

Harassment affects the educational outcomes of sexual minority youth. Large population-based studies have found that sexual minority youth are significantly more likely than their heterosexual peers to be threatened or harassed at school and to skip school because they feel unsafe (Goodenow, Szalacha, & Westheimer, 2006; Robin et al., 2002). Sexual minority youth also report lower levels of school belonging (Galliher, Rostosky, & Hughes, 2004; Rostosky, Owens, Zimmerman, & Riggle, 2003) and more negative attitudes about school and difficulties in school (Russell, Seif, & Truong, 2001). Sexual minority students are also less likely to perceive that there is an adult at school that is available to them for support (Goodenow, Szalacha, & Westheimer, 2006). The combined effect of a negative school environment and meager social support increases the risk for poor educational outcomes (Kosciw & Diaz, 2006; Murdock & Bolch, 2005).

Strong social support from family, from peers, or from other gay-affirmative adults (including teachers and other school personnel) may buffer at least some of the effects of minority stress on sexual minority youths. However, sexual minority youths who do not enjoy adequate social support or who have difficulty coping with the levels of minority stress in their lives may be at increased risk for poor psychosocial outcomes. While the majority of sexual minority youths develop coping strategies and coping resources that help to minimize the effects of minority stress, the overall higher rates of

psychological distress (Elze, 2002; Udry & Chantala, 2002) and substance abuse problems (Rostosky, Owens, & Zimmerman & Riggle, 2003; Russell, Driscoll, & Truong, 2002) among these youths are of serious concern. For example, research has established links between the school bullying and victimization experiences of sexual minority youth and their higher rates of suicidality and depressive symptoms (Bontempo & D'Augelli, 2002; Goodenow, Szalacha, & Westheimer, 2006).

CHARACTERISTICS OF SCHOOLS AND CLASSROOMS REGARDING RISK

Providing access to safe schools for all children and adolescents is a necessary requirement for positive educational outcomes. The increased risks of harassment and educational disruption and interruption for sexual minority youths must be addressed at multiple levels. First, state-wide legislation that comprehensively and specifically protects students of all socially disadvantaged groups must be enacted. The majority of GLB students in the United States are not protected, and research has demonstrated that blanket coverage through generic legislation that does not enumerate protected categories is no more effective in reducing harassment than no legislation at all (Kosciw & Diaz, 2006).

District-wide and school-level establishment and enforcement of strong anti-bullying policies that are comprehensive and inclusive of sexual orientation sends a strong message that all students will be protected from physical and psychological harm. Research findings indicate that GLB students in schools with comprehensive anti-bullying policies that include sexual orientation are more likely to report harassment, and teachers in such schools are more likely to intervene in such harassment than those GLB students and teachers in schools with generic anti-bullying policies (Kosciw & Diaz, 2006).

Safe schools create and adopt inclusive curricula that affirm the intrinsic worth of all individuals, including those who are sexual minorities. All students, including sexual minority students, have a right to a school environment that is safe and that facilitates rather than inhibits learning. Integrating sexual minority lives into classroom curricula models acceptance and appreciation of diversity. Resources on GLBT-related topics should be made available in the library and on the Internet. Students should be exposed to positive representations of GLBT issues, achievements and contributions, and current events.

At the classroom level, appropriate professional training on issues related to sexual minority youths and families should be provided since the majority of GLBT students indicate that they talked with a teacher at least once during the previous school year (Kosciw & Diaz,

2006). Unfortunately, many teachers and school staff lack even basic knowledge about sexual orientation and, therefore, are unprepared to provide information, protection, or support to their sexual minority students (Ryan & Rivers, 2003). Beyond providing support to these students, however, teachers and staff need to be trained in and encouraged to exercise skills in confronting the use of derogatory language and in effectively intervening in anti-gay bullying and harassment. Such training has been demonstrated to be significantly associated with an improved school climate (Szalacha, 2003).

School personnel should also be provided with resources (time, expertise, rewards) for grappling with their own assumptions about and biases toward others who are different from themselves. To provide effective multicultural education for students, school personnel must first have opportunities to address the ways they as individuals have personally benefited from and suffered from power hierarchies attached to social categories. This type of professional development requires a safe and trusting environment and investments of time, effort, and resources. However, the effect of this investment on school climate and educational outcomes can be significant.

At the student level, research has shown that sexual minority youths who perceive that their teachers are supportive of them and that their school environment is not rejecting of them report better school-related adjustment (Murdock & Bolch, 2005). Schools should be safe places for both GLBT students and teachers. In the 2005 school climate survey, over half of sexual minority students reported that they did not know an *out* teacher or school staff member (Kosciw & Diaz, 2006).

Finally, sexual minority youths in schools with gay/straight alliances (GSAs) or other types of groups aimed at providing support and ending discrimination and prejudice are less than half as likely as sexual minority students in other schools to report school victimization or to skip school due to fear of victimization (Goodenow, Szalacha, & Westheimer, 2006). Attending a school with a GSA (or similar support group) or perceiving that one has access to a school staff person to whom one could go for support is associated with lower rates of suicidality (Goodenow, Szalacha, & Westheimer, 2006). Principals and other school administrations need to visibly and vocally support of these groups.

SOME SUGGESTED RESOURCES FOR EDUCATORS

Safe Schools Coalition (<http://www.safeschoolscoalition.org>) has lesson plans and handouts for addressing issues of sexual diversity in age appropriate ways in the classroom. There are also many resources for sexual minority

youths and their friends and allies, including greeting cards that can be downloaded.

The American Psychological Association's Healthy Lesbian, Gay, and Bisexual Students Project was founded "to strengthen the capacity of the nation's schools to prevent the behavioral health risks of lesbian, gay, and bisexual students through knowledge development, dissemination, and application, working with and through national organizations of school stakeholders." Their Web site (<http://www.apa.org/ed/hlgbaboutus.html>) provides links to national education organizations' policies and the latest research on sexual minority youths, including a link to *Just the Facts About Sexual Orientation & Youth: A Primer for Principals, Educators and School Personnel*.

The Gay, Lesbian, and Straight Education Network (<http://www.glsen.org>) "strives to assure that each member of every school community is valued and respected regardless of sexual orientation or gender identity/expression." More than 1,000 resources related to current events and issues, tools for ensuring safe schools, policies and legal issues, and lesson plans and curricula for the classroom are available from its Web site.

Advocates For Youth Gay, Lesbian, Bisexual, Transgender and Questioning (GLBT) Youth Initiative (<http://www.advocatesforyouth.org/about/glbqtq.htm>) "works to address homophobia within communities, sensitize youth-serving professionals to the needs of GLBTQ youth and to encourage GLBTQ youth to become powerful advocates for themselves and other youth by sharing culturally relevant information and access to tailored services." Available at this Web site are tips for teachers and teens for dealing with harassment and for creating inclusive programs. Several fact sheets and tip sheets are available for transgender youth and for the adults in their lives.

Parents, Friends, and Families of Lesbians and Gays (<http://www.pflag.org>) offers support and information for families of LGBT people with more than 400 chapters nationwide. PFLAG offers Safe Schools Training for school personnel.

Children of Lesbian and Gays Everywhere (<http://colage.org/>) was formed "to engage, connect, and empower people to make the world a better place for children of lesbian, gay, bisexual, and/or transgender parents and families." The Web site offers a link to "Tips for making the classroom safe for children with LGBT parents," as well as lists of books and films.

SHARED COGNITION

Shared cognition occurs when two or more people intertwine their thinking processes, yielding feelings of "being on the same page" and often leading to intellectual accomplishments that "belong to us." In some settings, such as when a mother and child playfully plan a tea party, shared cognition may appear to occur naturally and effortlessly. Indeed, the basic mechanisms underlying shared cognition are readily available to school-age children and adults. Yet in many situations, shared cognition does not easily occur. Partners can bring very different life experiences, assumptions, and knowledge to their joint efforts, creating the need for strategies that can bridge their unique perspectives. Shared cognition, then, is an achievement realized in a designed environment through intentional and skillful interaction.

Both formal and informal learning settings can encourage the development of shared cognition, and doing so can have benefits both for individual learning and for students' future life opportunities. Research has shown that collaborative approaches to learning are beneficial for individual and collective knowledge growth, including the development of disciplinary practices. Studies also indicate that collaborative approaches can help students develop positive affective qualities, such as confidence and motivation. Teachers can support the expression and development of collaborative capacities through the careful design of activities, assessments, and methods for establishing and maintaining classroom norms that support productive joint work.

TRADITIONAL AND KNOWLEDGE WORK PERSPECTIVES

Traditional perspectives on learning view collaboration instrumentally. For example, a teacher may ask students to work together, but only count their individual test results toward their grade. Alternatively, a knowledge work perspective can lead to seeing collaborative learning as valuable in itself, because collaborative learning reproduces a desirable cultural practice of sharing cognition. For example, *Science for All Americans, Project 2061* (American Association for the Advancement of Science, 1989) argues:

The collaborative nature of scientific and technological work should be strongly reinforced by frequent group activity in the classroom. Scientists and engineers work mostly in groups and less often as isolated investigators. Similarly, students should gain experiences sharing responsibility for learning with each other. In the process of coming to understandings, students in a group must frequently inform each other about procedures and meanings, argue over findings, and assess how the task is progressing. In the context of team responsibility, feedback and communication become more realistic and have a character very different from the usual individualistic textbook homework recitation approach. (p. 202)

THE SCOPE OF SHARED COGNITION

Shared cognition is one of several overlapping concepts: Intersubjectivity, social cognition, collective cognition, distributed cognition, group cognition, team cognition, collective consciousness, communities of practice, grounding processes in conversations, and transactive memory are all foci of research on how people learn together. To give a sense of the possible scope of shared cognition, we briefly review two concepts, intersubjectivity & joint problem solving, that are closely related to the notion of shared cognition, and the somewhat contrasting perspective of distributed cognition.

Intersubjectivity. Intersubjectivity refers to shared understanding of what has been happening and what is going to happen next. The concept of intersubjectivity has also been central in studies of infant-parent interaction. Some definitions of intersubjectivity build on a sharing metaphor, highlighting overlap and coming to consensus. Other definitions focus on the dynamics of mutual engagement and pay equal attention to disagreement, diversity of views, and conflict (Matusov, 1996). In this view coordination of perspectives is emphasized and intersubjectivity can be achieved without agreement or complete overlap of perspectives.

Joint Problem Solving. Problem solving emerged in cognitive psychology as the signature cognitive activity. When solving problems together, people often find the need to share goals, ideas, plans, explanations, justifications, judgments, and many other aspects of intellectual life. For example, students can develop shared understanding of an “if-then” problem-solving rule (e.g., if the slope is steeper, the rate is faster) by spreading the parts across utterances (“Look, it’s steeper!” “So, we *know* it’s going faster.”) A distinction is made between cooperation or coordination, in which partners merely agree on breakdown of work, and true collaboration, in which partners help each other think the problem through (Teasley & Roschelle, 1993).

Distributed Cognition. Distributed cognition expands the unit of analyses beyond interacting partners to include the cognitive affordances of multiple partners, tools, and representations. A well-known example comes from Ed Hutchins (1995) who analyzed the navigation of a ship coming into harbor and showed that successful navigation of the ship was dependent on complex coordinations between the knowledge of team members, measurement tools, and representational systems. Based on this and other analyses he argued that human intelligent action is productively conceived as an accomplishment that arises from *properties of interactions* between people or between people and artifacts in the world.

BUILDING BLOCKS OF SHARED COGNITION

Close analyses of conversations have led to deeper understanding of building blocks that support the accomplishment of shared cognition. Four building blocks are discussed below.

Joint Attention. Joint attention is first observed between 9 and 15 months (Adamson & Bakeman, 1991). Studies of infant-mother interaction provide interesting insights about the subtle ways in which partners help regulate the attention of the other and highlight how both partners are active contributors to the process. Achieving joint attention during problem-solving situations depends on the mutual intent of group members to share a focus and come to a common understanding.

Making and Acknowledging Contributions. Participants build a sense of shared cognition through interactions that make and acknowledge contributions (Clark, 1996). Participants take knowledge to be shared only after a first participant’s bid to introduce an idea is accepted by a second participant. This can occur in two short utterances or be the result of a lengthy deliberation.

Grounding. The everyday phrase “finding common ground” is a practical solution to a pervasive problem in sharing cognition: How can participants tell if an idea is mutually understood? A simple “uh, huh” provides weaker evidence than a more elaborate paraphrase that participants agree on. Common ground can also be found in action; smooth translation of ideas to satisfactory joint actions is good evidence the ideas were shared. Conversational analysis shows that people flexibly apply a variety of grounding strategies and criteria of mutuality depending on the purposes of communication and the channels of communication available (Clark & Brennan, 1991).

Repair. Of course, attempts to share cognition often go astray. Successful collaborators notice divergence and engage in repairs. For example, in baking a cake one might have the following exchange: “The recipe called for 1 teaspoon of baking soda.” “No, baking *powder*.” “OK, I’ll put in 1 teaspoon of baking powder.” In this set of three utterances, by saying no and emphasizing the word *powder* the second person repairs the misconception of the first and the two people achieve shared knowledge of the right ingredient.

Although these building blocks have been described in generic terms, one can imagine their application to classroom situations. In order to share cognition, teachers and students must also achieve joint focus of attention, make and acknowledge contributions, find common ground, and repair misunderstandings.

In one example, researchers observed students constructing a “joint problem space” (Roschelle, 1992; Teasley & Roschelle, 1993). A joint problem-solving space was defined as a shared conceptual structure developed in the course of collaborative work. In a study of two girls using a computer simulation designed to provide a dynamic view of velocity and acceleration, Roschelle (1992) argued that the creation of a joint problem-solving space was accomplished through repeated cycles of displaying, confirming, and repairing understandings. As the conversation progressed, the students expected increasingly explicit evidence that they understood one another.

HOW SHARED COGNITION CONTRIBUTES TO LEARNING

Theorists have given varied accounts of how shared cognition leads to learning. More recently, researchers have developed more specific accounts and analyses.

Conflict was central in the theory of Jean Piaget (1896 1980) about how social exchange can result in cognitive development (Piaget, 1932). Different perspectives on the same problem can lead to disagreements, de-centering from one’s own perspective, more advanced

stages of cognitive development, and sometimes mutual understanding.

Interaction within a *zone of proximal development* was central to the theory of development put forward by Lev Vygotsky (1896 1954) (Vygotsky, 1978). This zone represents the level of challenge at which a learner cannot independently accomplish a task but can do so with the help of a more expert peer or teacher. *Internalization* occurs because the child is actively playing a role in the joint activity and the more expert partner is attending to when and where assistance is needed. The child comes to own not only skills but the cultural tools that have been developed over long periods of time, such as writing systems, maps, language, and numerical systems.

More recently, investigators have offered more detailed explanations of how group work can support individual learning. These include opportunities to share original insights (Bos, 1937), resolve differing perspectives through argument (Amigues, 1988; Phelps & Damon, 1989), explain one’s thinking about a phenomenon (King, 1990; Webb, Troper, & Fall, 1995), provide critique (Bos, 1937), observe the strategies of others (Azmitia, 1988), listen to explanations (Coleman, 1988; Hatano & Iganaki, 1991), and generate new insights through shared abstract representations, such as diagrams (Jeong & Chi, 2007; Schwartz, 1995).

Increasingly it is recognized that asking learners to work in groups does not automatically lead to interactions that capitalize on the knowledge and skills of all group members. One of the most challenging aspects of group projects involves developing an understanding of what knowledge is shared and what knowledge members hold uniquely. The extent to which learners come to a common or shared understanding of their efforts can vary, depending on multiple factors including their prior experiences, their personal relationships, broader power structures in society, and the extent to which their goals for the task are aligned.

Research that attends explicitly to variability in group interaction has provided information about how relational challenges can interfere with the shared cognition, even when collaborators have similar levels of prior knowledge. Barron (2003) analyzed the interactions of 16 triads in order to understand the sources of variability in how well the students collaborated and how much individuals learned. She found less joint attention in groups in which partners were competing, and this translated into poorer performance even when correct solutions were voiced. If a collaboration is going well: (1) many students will be involved in the discussion as contributors and responders, (2) the contributions are coordinated rather than consisting of many independent, unrelated conversational turns; (3) students attend to

one another and to their work in common as indicated by eye gaze and body position. These are good markers of *mutual engagement and joint attention*, important elements of collaborative work.

SCHOOLING PRACTICES

A great deal of work has been done to specify the kinds of tasks, accountability structures, and roles that help students collaborate well. It is generally agreed that tasks requiring interdependence of team members, accountability structures at the group and individual level, and opportunities to reflect on group progress and interaction are key elements. Two approaches, complex instruction and jigsaw, are described below.

Complex Instruction. Cohen and her colleagues developed *Complex Instruction*, one of the best-known and well-researched approaches. Complex Instruction uses carefully designed activities that require a diversity of talents and interdependence among group members. Teachers are encouraged to pay attention to unequal participation that often results from status differences among peers and are given strategies that will allow them to bolster the status of infrequent contributors (Cohen & Lotan, 1997). In addition, roles are assigned that support equal participation. The roles include a recorder, a reporter, a materials manager, a resource manager, a communication facilitator, and a harmonizer. A major aspect of the approach is the development of “group-worthy tasks” that are both sufficiently open-ended and multi-faceted in their cognitive demands to require and benefit from the participation of every member of the group.

Jigsaw Method. The jigsaw method divides topics among students so that each class member becomes an expert in a subtopic. Experts then teach their group members what they know so that the group benefits from the distributed work. For example, groups of four to five students might be asked to write proposals to study a specific animal species (Engle & Conant, 2002). The groups are then assigned an animal based on the quality of their group proposal. A final product of the group is required, such as a written report to which all members of the group contribute. Individual students become expert on a specific subtopic, such as reproduction strategies or defense mechanisms, and contribute chapters that focus on these subtopics. After they have shared this knowledge with their group, the entire group writes the introduction and conclusion.

IMPLICATIONS

Education traditionally downplays the importance of shared cognition in favor of sequestered test-taking skills. This bias appears shortsighted in an era driven by the intellectual accomplishments of teams. By understanding the building blocks of shared cognition, the ways in which shared cognition can enhance learning, and research-based school practices, educators can enable students to learn both subject matter content and how to succeed in realistic adult tasks.

SIMON, HERBERT (ALEXANDER) 1916–2001

To the outside world American psychologist and computer scientist Herbert Alexander Simon (1916–2001) appeared to be a Renaissance man. A political scientist who won a Nobel Prize in economics (1978) and the first National Medal of Science for behavioral sciences, Simon pioneered artificial intelligence and made significant contributions in diverse fields, including philosophy, physics, the history of science, business administration, and the psychology of learning. Yet Simon described himself as a monomaniac singularly focused on understanding the processes of human learning, problem solving, and decision making.

Born and raised in Milwaukee, Wisconsin, Simon became interested in decision-making processes as an undergraduate at the University of Chicago. There he conducted a study on the administration of the Milwaukee Recreation Department for Clarence Ridley's course on evaluating city government. After earning his BA in political science in 1936, Simon became Ridley's assistant at the International City Managers' Association in Chicago. In 1939 Simon moved to the University of California at Berkeley to head a three-year study on local

government, while completing his doctorate from Chicago on decision-making in organizations.

In 1942 Simon joined the political science faculty at the Illinois Institute of Technology, becoming department chair in 1946. There he continued his collaborations at the University of Chicago and the Cowles Commission for Research in Economics. In 1949 Simon joined the new Graduate School of Industrial Administration at the Carnegie Institute of Technology (later Carnegie-Mellon University) in Pittsburgh, Pennsylvania. He remained there for the rest of his life, from 1965 on as the Richard King Mellon University Professor of computer science and psychology.

Simon challenged a basic tenet of classic economic theory when he argued that business decision-makers could not have enough information to maximize profits. He developed the theory of "satisficing" or "bounded rationality" to describe the balancing of factors for making satisfactory rather than optimal decisions. Later Simon applied his theory to the teaching of algebra.

In the 1950s Simon began using computers to study how humans think and learn, with a goal of improving teaching methods. In early experiments with Allen Newell and Clifford Shaw of the RAND Corporation, Simon had subjects verbalize their reasoning while working through problems in logic. These human problem-solving processes were then codified as computer programs. The Logic Theorist program and subsequent General Problem Solver were the first computer programs to simulate human reasoning and the forerunners of artificial intelligence. Simon and his colleagues subsequently developed computer programs as models of other human cognitive processes, including learning.

According to Simon, educational programs should first determine what students need to know and then design experiences that result in learning the desired skills and information. For example, geometry teachers should begin by determining what students need to know to solve problems and prove theorems and then design the appropriate learning experiences. Simon and his colleagues found that working through step-by-step examples of solutions to problems was a powerful learning method. As the students worked through the examples, they learned how to get from one step to the next. Subsequently Simon developed computer programs that learned new skills by examining worked-out solutions to problems. In other experiments Simon and K. Anders Ericsson demonstrated that the verbalizing of thought processes often improved student learning.

While developing computer programs for playing chess, Simon found that pattern recognition rather than analysis was a key to learning and developing expertise. He concluded that more emphasis should be

placed on teaching pattern recognition. During the 1980s Simon also studied short-term memory with Chinese colleagues and used computers to simulate human memory processing and determine the limits of short-term memory. The researchers discovered that it takes eight seconds to learn a pattern for one day, but substantially longer to learn a pattern permanently.

Using computer programs as models Simon and colleagues at the Chinese Academy of Sciences designed a middle-school curriculum in algebra and geometry. Traditional algebra textbooks explained the rules for solving equations, but not how to decide which rule to use. In their experimental classrooms, large groups of students learned algebra by working through examples, while the teacher tutored individual students rather than lecturing. Simon found that the children learned algebra about 50% faster than with traditional methods. By 1998 the curriculum was being used in some 200 Chinese schools.

Simon and his colleagues at Carnegie-Mellon were pioneers in the use of computers in education. To design computer displays for teaching, Simon set out to determine what humans were capable of visualizing, how they visualized, and how students utilized visual material. For example he observed what students doodled as they tried to understand complex problems in math and physics. Simon died in Pittsburgh at the age of 84.

Ericsson and others subsequently extended Simon's findings on learning and the acquisition of expertise and applied it to K-12 education.

SINGLE-CASE DESIGNS

The term *single-case designs* refers to a family of research designs that are true experiments. They can be used to infer causal relationships between an intervention program (e.g., in education, therapy, rehabilitation) and change in client functioning and behavior. The unique feature of these designs is the capacity to conduct experimental investigations with the single case, that is, one subject or one group. However, the designs can evaluate the effects of interventions with multiple subjects and groups.

CHARACTERISTICS AND UNDERPINNINGS OF THE DESIGNS

There are key features of the designs that are pivotal for drawing causal inferences. As with designs in the quantitative-group tradition, control and comparison of conditions, prediction, and testing of predictions are all central. These are accomplished in novel ways in single-case designs.

Logic of the Designs. The designs draw causal inferences based on how the assessment information is used over the course of the design. Each design includes phases or periods of time (e.g., week, month) in which baseline (no intervention) or intervention are presented (e.g., to one or a few individuals or a group). The designs usually begin with a baseline phase, a period of observations before the intervention is implemented. The data in this phase have two purposes: to describe current performance and predict what performance is likely to be in the immediate future without an intervention. After the baseline pattern is clear, an intervention is implemented in a new phase, all the while data are being collected. Data in the intervention (and any subsequent phases) have three purposes: to describe as in baseline; to predict what performance would be likely if the intervention were to continue, and to test the prior prediction from baseline. Baseline is used to predict likely performance; if the intervention is having any effect in the next phase the data ought to depart from that projected level of performance.

Essentially, single-case designs are based on describing, predicting, and testing predictions. The logic of this is exactly like that of experiments in the quantitative-group tradition, in which describing performance without intervention and testing whether the intervention

departs from that is achieved by a control group of subjects (e.g., no treatment, waiting list). In single-case and group research methods, the question is whether the intervention (variable, experimental manipulation) made a difference in a way that departs from the control phase or group, respectively.

Assessment Requirements. The most fundamental design requirement is repeated observations of performance over time. The performance of one or more clients is observed on several occasions, usually before the intervention is applied and continuously over the period while the intervention is in effect. Typically, observations are conducted on a daily basis or at least on multiple occasions each week to provide the information to describe, predict, and test predictions, as noted previously. Continuous assessment provides the observations that allow the comparisons of interest (e.g., intervention versus no intervention) within the individual subject.

Because baseline performance is used to predict how the client will behave in the future, it is important that the data are stable. Data stability refers to minimal fluctuation or variability in the subject's performance over time. Excessive variability in the data during baseline or other phases can interfere with drawing conclusions about treatment. Whether the variability is excessive and interferes with drawing conclusions about the intervention depends on many factors, such as the initial level of behavior during the baseline phase and the magnitude of behavior change when the intervention is implemented.

MAJOR EXPERIMENTAL DESIGN STRATEGIES

There are many single-case designs that vary in the way the intervention is presented and evaluated over time. Three designs are presented here to illustrate the methodology.

ABAB Design. As with all of the designs, continuous observations of performance are made over time for a given client (or group of clients). In ABAB design, typically two separate phases are alternated over time, including the baseline (A phase), when no intervention is in effect, and the intervention (B phase). The A and B phases are repeated again to complete the four phases. The effects of the intervention are clear if performance improves during the first intervention phase, reverts to or approaches original baseline levels of performance when the intervention is withdrawn, improves when the intervention is reinstated in the second intervention phase, and again changes in the final intervention phase.

The most commonly used version of the ABAB design has been discussed here as a four-phase design

that alternates a single intervention with baseline phases. However, designs are available that include more than one treatment and more than four phases or that end with a new phase in which procedures are included to maintain the gains. For example, suppose that the treatment (B1) does not change behavior after the baseline phase. The investigator would not continue the phase but would try another treatment (B2). This latter treatment would constitute a new phase and would probably be implemented later in the design. The design could be represented as an AB1 B2 AB2 design.

As a general rule, problems related to reversing behavior make the ABAB design and its variations undesirable in educational and other applied settings. If a reversal does occur, that may be problematic if the behavior is important for the clients or for those in contact with them. If a reversal does not occur, this raises obstacles in concluding that the intervention led to the change. Yet the power of the design in demonstrating control of an intervention over behavior is very compelling. If behavior can, in effect, be turned on and off as a function of the intervention, this is a potent demonstration of a causal relation. Other designs can also demonstrate a causal relation without using a reversal of conditions.

Multiple-Baseline Designs. These designs evaluate change across different baselines that refer to two or more: behaviors of a given individual, individuals, settings, or time periods. The intervention is introduced to the different baselines at different points in time, for example, in a staggered fashion. Ideally, change occurs when the intervention is introduced in sequence to each of the baselines. The different baselines might, for example, consist of three children in a classroom (or three entire classrooms). Each child's behavior is observed and graphed separately. After baseline observations, the intervention is introduced to one of the children. The other children continue to be observed and remain in a baseline phase. Later the intervention is introduced to the other children in a staggered fashion so that by the end each is receiving the intervention. The effect of the intervention is demonstrated by showing that the behavior of each child changed when and only when the intervention was introduced.

Multiple-baseline designs are user friendly in educational and clinical applications because the intervention is applied in a gradual or sequential fashion across different responses of the individual (or different individuals, or different situations). If the intervention is effective, then it can be extended to all of the other responses for which change is desired. As important, if the intervention is not effective or not effective enough to achieve important changes, it can be altered or improved before it is extended.

Changing-Criterion Design. This design demonstrates the effect of an intervention by showing that behavior changes in increments to match a performance criterion. The design begins with a baseline phase after which the intervention is introduced. When the intervention is introduced, a specific level of performance is chosen as a criterion for the client. The daily criterion may be used as a basis for providing response consequences or an incentive (e.g., token reinforcement). When the performance meets or surpasses the criterion level on a given day (e.g., certain number of cigarettes smoked, number of calories consumed), the response consequence (e.g., tokens) is provided.

A specific criterion usually is invoked continuously for at least a few days. When performance consistently meets the criterion, the criterion is made more stringent (e.g., fewer cigarettes or calories consumed daily). Consequences are provided only for meeting the new criterion on a given day, and the criterion again is changed if the performance meets the criterion consistently. The criterion is repeatedly changed throughout the intervention phase until the terminal goal of the program is achieved. A causal relation between an intervention and behavior is demonstrated if behavior matches a constantly changing criterion for performance over the course of treatment. By implementing a given criterion for at least a few days (or even longer), the behavior shows a step-like effect that is not likely to result from a general incremental change occurring as a function of extraneous events.

As with the multiple-baseline design, the changing-criterion design can be quite compatible with demands of the applied settings. Many therapeutic regimens focus on gradual development of behavior or skills (e.g., improving reading comprehension or participation of activities) or reduction of problematic function (e.g., overcoming anxiety). Shaping these behaviors or gradually exposing individuals to an anxiety-provoking situations may proceed in ways that can reflect increasing the performance criteria as changes are evident. Thus, progress can be monitored and evaluated in a changing-criterion design.

DATA EVALUATION

Data evaluation refers to the way the numbers are examined to infer whether there was a veridical intervention effect. Investigators working with single-case designs as a matter of choice often prefer nonstatistical evaluation of the data, a method referred to as visual inspection. Visual inspection depends primarily on examining four characteristics of the data across phases of the design:

Changes in means: Consistent changes in means (average) across phases;

Changes in level: A shift or discontinuity of the data point from the end of one phase to the beginning the next phase; an index of the immediacy of change;

Changes in slope or trend: Changes the direction (e.g., accelerating or decelerating slope) of behavior as the intervention is applied or withdrawn; and

Latency of the change: The more immediate the change after a phase is altered, the more likely the intervention can be inferred to be responsible for change.

Although visual inspection is the most frequently used method of data evaluation, statistical tests are available and often applied to the data. Statistical tests for single-case designs consist of methods (e.g., time-series analyses, randomization tests) not usually taught in social and biological sciences. Characteristics of single case data (autocorrelation) often preclude the straightforward application of more familiar statistical tests.

STRENGTHS AND LIMITATIONS

There are strengths of the designs. First, they are well suited to evaluating interventions in diverse settings. Most programs in schools, institutions, the home, and the community at large are not evaluated empirically and have no evidence in their behalf in part because randomized controlled trials are not feasible. Single-case designs permit careful and rigorous evaluation. Second, the designs allow for changes during a study, a feature that is well suited to applied settings. If the intervention is not working well or optimally, modifications can be made, and the design can continue to provide a rigorous evaluation. Third, the designs can address many questions of interest in intervention research beyond the effects of a particular intervention such as the components of the intervention that contribute to change and the relative effectiveness of two or more interventions.

There are limitations as well. First, when only one or a few subjects are used, there is difficulty in identifying characteristics (moderators) that might explain why some individuals respond better than others or do not respond. The sample is inherently too small to conduct post hoc analyses of characteristics (e.g., by age, sex, ethnicity) that might influence responsiveness to treatment.

Second, an oft-cited but probably misunderstood concern or limitation is the extent to which the results with one or a few subjects can generalize to others not included in the study. This concern has not proven to be an issue. Also, the concern reflects a misunderstanding of group research; when means are compared one has no idea within a study how many individuals responded. In addition, unless the group was randomly selected from a population, generalizing beyond the sample is a problem.

Tests of generality invariably require replication. The limitation of single-case designs is not generality of the effects but identifying the dimensions or categories which may influence the extent to which the intervention exerted impact.

Finally, the use of visual inspection can be a limitation of the designs. When the visual inspection criteria are not clearly met, agreement on interpretation of the data becomes less clear. Studies of how individuals invoke the criteria for visual inspection have shown that judges, even when experts in the field, often disagree about particular data patterns and whether the effects were reliable.

APPLICATIONS IN EDUCATIONAL SETTINGS

Single-case designs have been used extensively in educational settings, from preschool through college. There is a special role for these designs in schools because school is often a place in which diverse programs are implemented and at different levels (e.g., classroom, schools, districts, and states and provinces). Among the many examples are programs with an academic focus (e.g., reading comprehension), study habits (e.g., homework compliance and completion), classroom deportment (e.g., decreases in disruptive behavior), risky behaviors among adolescents (e.g., substance use, unprotected sex), skill acquisition (e.g., voice, musical instrument), and safety (e.g., driving). It is not feasible to even consider randomized trials to evaluate such programs. Single-case designs are quite useful for evaluation in general and in the many situations in which there is or cannot be a control group. Single-case designs and programs in educational (but other institutional settings) are a natural combination because one can develop the program by examining its impact on student functioning, can make changes during the evaluation to improve the program, and identify causal relation between interventions and outcomes without the constraints of large samples, random assignment, and control condition.

Single-case designs are rarely taught in graduate training in social and biological sciences. This is unfortunate because people in education, psychology, counseling, medicine, and other disciplines frequently are interested in evaluating interventions at the level of the individual, groups, and institutions. The designs can be used in applied settings and hence serve as a way to translate laboratory findings to real world settings as well as identifying promising interventions that might warrant further research in laboratory settings.

SITUATED COGNITION

Many practices of conventional schooling consider knowledge and skill as discrete structures of cognition that can be adequately transferred from teachers to students in classrooms and studied in laboratories. Knowing and thinking, in this view, are assumed to go on in individual minds isolated from the complexity of the world outside, from which abstract knowledge can be successfully distilled. However, a growing body of research that considers cognition and learning in activities outside specialized learning environments is undermining the plausibility of these presuppositions (e.g., Brown, Collins & Duguid, 1989; Engeström, 2001; Greeno, Collins, & Resnick, 1996; Hutchins, 1995a; Lave & Wenger, 1991; Nersessian et al., 2003; Rogoff, 1990; Rogoff & Lave, 1984). This research supports the view that knowing and learning by individuals are inextricably situated in the physical and social contexts of their acquisition and use. It is a mistake to think that classrooms or laboratory experiments produce knowledge or follow principles of learning that are somehow context-free. Cognition and learning by individuals always occur in a context; the issue has to be what the context is, not whether there is one.

For most of time between 1950 and the early 2000s, active research programs have been studying structures and processes of social interaction, as well as cognitive processes of representing and transforming information. But these research programs have been largely separate from each other. Situative research and theorizing attempts to unify the two perspectives of individual cognitive theory and the analysis of interactional structures and processes. The primary level of a situative analysis is an activity system, in which one or more individuals participate along with material and informational resources in the environment. Cognitive processes are understood as aspects of the practices of

a community or group. Studies include analyses of perceiving (Goodwin, 1996), remembering (Hutchins, 1995b), reasoning and understanding (Greeno & Van de Sande, 2007; Ochs, Gonzales, & Jacoby, 1996), and learning (Bowers, Cobb, & McClain, 1999; Engeström, 2001; Engle, 2006; Stenning et al., 2002). In these analyses, successful cognitive performances are considered as part of an interactive system, and analyses focus on how the multiple participants coordinate their contributions. Information structures, which the individual cognitive perspective attributes to individual minds, are attributed in the situative perspective to the interacting group as achievements of communication that enter the group's common ground (cf. Clark, 1996). Such analyses do not preclude also having analyses of the same events that focus on one or more individual participants, identifying their respective contributions to the interactions and explaining these in terms of their individual capabilities, and with other participants and systems considered as the context (cf. Bowers, Cobb & McClain, 1999; Hatano & Inagaki, 2003).

If knowing is understood as successful situated participation, then many conventional assumptions must be questioned. In particular, a situative theory of knowing challenges the widely held belief that abstraction of knowledge from situations is the key to transferability. An examination of the role of situations in structuring knowledge suggests that abstraction and explication provide an inherently impoverished and often misleading view of knowing. Knowing by an individual is fundamentally a capability of the person to interact in the world. In this view, hypotheses or assessments of an individual's or group's knowing are about their capabilities for interacting in situations. Hypotheses that represent knowledge only as abstract propositions do not capture the densely interwoven nature of knowing.

The situative perspective views knowing as distributed among people and their environments, including the objects, artifacts, tools, books, and the communities of which they are a part. Analyses of activity focus on processes of interaction of individuals with other people and with physical and technological systems. Several research traditions have contributed to the situative perspective. The best established of these is ethnography, including the study of cultural practices and patterns of social interactions, as well as discourse analysis and conversation analysis in activity theory, sociolinguistics, anthropology, and sociology. Another research tradition is ecological psychology, which studies behavior as physical interaction in which animals, including people, participate in physical and technological systems. A third research tradition is situation theory in logic and philosophy, which analyzes meaning and action as relational systems and is developing a reformulation of logic to support these relational analyses. Knowing in this per-

spective is both an attribute of groups that carry out cooperative activities and an attribute of individuals who participate in the groups. Learning by a group or individual involves becoming attuned to constraints and affordances of the material and social systems with which they interact. Discussions of motivation in this perspective often emphasize engagement of individuals with the functions and goals of the community, including interpersonal commitments and ways in which individuals' identities are enhanced or diminished by their participation.

APPRENTICESHIP AND IDENTITY

When knowing is viewed as practices of communities and of the abilities of individuals to participate in those practices, then learning is the strengthening of those practices and participatory abilities. Systems in which individuals learn to participate in social practices are very common and include apprenticeship and other forms of being initiated into the practices of a group. Lave and Wenger (1991) reviewed several studies of learning by newcomers to communities of practice and concluded that a crucial factor in the success of such a system is that learners must be afforded legitimate peripheral participation, which involves access to the practices that they are expected to learn and genuine participation in the activities and concerns of the group.

Lave and Wenger characterized learning of practices as processes of participation in which beginners are relatively peripheral in the activities of a community, and as they become more experienced and adept, they progress toward fuller participation. A crucial issue in the nature of learning is whether, and in what ways, the peripheral participation of beginners is legitimate. They described four cases of learning by newcomers and emphasized how learners' identities derive from being part of the community as they become more fully participating members in the community. They also noted that an apprenticeship relationship can be unproductive for learning, as in a case of meat cutters they cited, where the apprentices worked in a separate room and were isolated from the working community. For an environment of apprenticeship to be a productive environment of learning, learners need to have opportunities to observe and practice activities in order to progress toward more full participation.

The degree to which people participate fully and are respected by other members of a community determines their sense of identity (Lave & Wenger, 1991; Wenger, 1998). The fully participative roles are those that most directly contribute to the collective activities and knowledge of the community. The motivation to participate more fully in a community of practice can provide a powerful incentive for learning. Smith (1988) argued that children learn to read and write if the people they

admire read and write. That is, they will want to join the “literacy club” and will work hard to become members. Learning to read is part of becoming the kind of person they want to become. Identity is central to deep learning.

An important aspect of learners’ identities are the ways that they are positioned in the participant structures (Phillips, 1972) of learning activities. An important distinction by Pickering (1995) involves different kinds of agency, called conceptual and disciplinary. Students who are positioned with disciplinary agency only participate as receivers and reproducers of the established meanings and procedures of the discipline, and their learning is evaluated only by whether they can perform procedures and explanations correctly. Students who are positioned with conceptual agency are expected to question and adapt concepts and methods of the discipline. For example, they might construct understandings that utilize disciplinary concepts in novel ways or consider alternatives to standard definitions of concepts. As an example, research by Boaler (2002) compared learning of mathematics in two English secondary schools and found that students who learned primarily through investigations understood mathematics as a general resource for understanding and problem solving, whereas students whose learning was primarily mastery of set procedures understood mathematics as a set of rules to be followed.

Wenger (1998) argued that people participate in a variety of communities at home, at work, at school, and in hobbies. In his view a community of practice is a group of people participating together to carry out different activities, such as garage bands, ham-radio operators, recovering alcoholics, and research scientists. Wenger stated: “For individuals, it means that learning is an issue of engaging in and contributing to the practices of their communities. For communities, it means that learning is an issue of refining their practice and ensuring new generations of members. For organizations, it means that learning is an issue of sustaining the interconnected communities of practice through which an organization knows what it knows and thus becomes effective and valuable as an organization.” (pp. 7–8).

The view that learning occurs through participation is at the root of the practices of apprenticeship, where apprentices are guided and supervised by masters. In successful apprenticeship learning, masters teach by showing apprentices how to do a task (modeling), and then helping them as they try to do it on their own (coaching and fading). Lave and Wenger (1991) emphasized how an apprentice’s identity derives from becoming part of the community of practitioners. The motive for becoming a more full participant in a community of practice can provide a powerful motivation for learning. Of course, what is learned in apprenticeship may not

generalize easily to other contexts. Collins, Brown, and Newman (1989) attempted to characterize how the modeling, coaching, and fading paradigm of apprenticeship might be applied to learning the cognitive subjects of school in an approach they called “cognitive apprenticeship.”

EDUCATIONAL APPLICATIONS OF THE SITUATIVE VIEW

A major goal of educational reform is to have students participate more actively and legitimately in learning communities, including participation in formulating and evaluating questions and problems, and constructing and evaluating hypotheses, evidence, arguments, and conclusions (Brown & Campione, 1996). Abilities for participating in these activities have to be learned, and the research literature on that kind of learning is sparse. Several projects have been focused on creating classroom practices of discussion and inquiry, and the investigators in those projects have discussed some aspects of the process of establishing norms and expectations by the students that support productive collaborative learning (Cohen, 1986; Lampert, 1990; Slavin, 1983).

In the view of learning as coming to participate more fully in a community of practice, transfer is often thought to be a problematic issue (e.g., Anderson, Reder & Simon, 1996). Viewed in the situative perspective, transfer can occur when learning leads to better performance or learning of new practices within a community (e.g., for school communities this might mean working new problems or accomplishing new kinds of tasks) or outside the community (e.g., for school these might be work environments such as those studied by Beach, 1995, and Saxe, 1990). Many of the resources and supports that occur within a community of practice do not carry over to a different community, and so the problem of transfer becomes one of marshalling the resources needed to be successful in a new environment. Doing so requires sophisticated social and information-processing skills, which are the kinds of skills that businesses think they will need in the future.

In a view of transfer in the situative perspective proposed by Greeno, Smith, and Moore (1993), transfer depends on constraints and/or affordances that are invariant under the transformations that change the learning situation into the transfer situation. For transfer to occur, learners must become attuned to those invariants in their initial learning. One of the ways to be attuned is to have an abstract representation that can apply in the new situation, but this is only one possible way for attunement to occur and may not be the typical way for many learned activities to generalize (Greeno, 1997).

Although the situative view insists that all cognition and learning are situated, learning designers who take a

situative perspective generally attend to the activity settings in which learning is to occur. For example, in goal-based scenarios (Schank et al., 1994; Nowakowski et al., 1994) learners are given real-world tasks and the scaffolding they need to carry out such tasks. They can be set either in computer-based environments or naturalistic environments. In one computerized goal-based scenario, learners are asked to advise married couples as to whether their children are likely to have sickle-cell anemia, a genetically linked disease. In order to advise the couples, learners must use the facilities in the system to find out how different genetic combinations lead to the disease and run tests to determine the parents' genetic makeup. There are scaffolds in the system to support the learners, such as various recorded experts who offer advice. Other goal-based scenarios support learners in a wide variety of challenging tasks, such as putting together a news broadcast, solving an environmental problem, or developing a computer-reservation system. Goal-based scenarios make it possible to embed cognitive skills and knowledge in the kinds of contexts where they are to be used. So people learn the basic competencies they will need and also when and how to apply these competencies.

Video and computer technology has enhanced the ability to create simulation environments in which students are learning skills in context. A novel use of video technology is the Jasper series developed by the Cognition and Technology Group (1997) at Vanderbilt University to teach middle-school mathematics. In a series of 15 to 20 minute videos students are put into various problem-solving contexts, for example, deciding on a business plan for a school fair or a rescue plan for a wounded eagle. The problems are quite difficult to solve and reflect the complex problem solving and planning that occurs in real life. Middle-school students work in groups for several days to solve each problem. Solving the problems develops a much richer understanding of the underlying mathematical concepts than the traditional school-mathematics problems.

Another novel use of technology is the curriculum developed by the Middle-school Mathematics through Applications Project (MMAP) at the Institute for Research on Learning (Goldman & Moschkovich, 1995; Greeno et al., 1999). The leading activities in the MMAP curriculum are design problems, supported by software that provide computer-aided design environments in which students design floor plans of buildings, models of population growth and decline, lexicographic codes, or geographical analyses of environmental quality. Mathematical reasoning and problem solving involving topics such as proportional reasoning, linear and exponential functions, and geometrical properties of geographical space are required for successful progress in the design activities. Printed curriculum materials are provided to support

teachers in organizing activities for students to encounter, recognize, and learn important mathematical concepts and methods.

These kinds of learning tasks are different from most school tasks because the contexts of most school tasks lack characteristics of practices that occur outside of school. Traditionally, academic material has been taught abstractly without practical real-world context; the equivalent to which might be learning tennis by being told the rules and practicing the forehand, backhand, and serve without ever playing or seeing a tennis match. If tennis were taught that way, it would be hard to see the point of what the students were learning. Yet in school, students are taught algebra and the works of Shakespeare without being given any idea of how they might be useful in their lives. That is not how a coach would teach students to play tennis. A coach might first show them how to grip and swing the racket, but very soon they would be hitting the ball and playing games. A good coach would have the students go back and forth between playing games and working on particular skills—combining global learning with focused local knowledge. The essential idea in the situative view of cognition is to consider learning and cognition as participation in an activity system. This view supports designers' and educators' efforts to tightly couple a focus on accomplishing authentic tasks with a focus on the underlying competencies needed to carry out the tasks.

For centuries, the epistemology that has guided educational practice has concentrated on abstract representations of concepts, assuming that knowing abstract concepts is a condition for acting and perceiving effectively in a broad range of situations. A situative theory of cognition suggests that conceptualization is embedded in activity and perception and that more attention needs to be focused on them. Learning through legitimate peripheral participation, enables learners to acquire and develop tools and skills, including conceptualizations, through authentic work and membership in communities of practice. Through this process, novices enter the culture of practice. So the concept of learning through legitimate participation helps to emphasize the centrality of activity in learning and knowledge and highlights the inherently content-dependent and enculturating nature of learning.

**SKINNER, B(URRHUS)
F(REDERIC)**
1904–1990

Burrhus Frederic Skinner (1904–1990) is considered by many to be the most influential psychologist of all time and by some to be one of the most influential people in history. A research scientist, author, and philosopher, his work has had a lasting impact on psychology, education, psychotherapy, psychopharmacology, philosophy, and even the business world.

Skinner was born March 20, 1904, in the small town of Susquehanna, in Pennsylvania, the son of a lawyer father and a housewife mother. He earned his undergraduate degree at Hamilton College in New York, intending to become a professional writer. Soon discouraged, a book about behaviorism by psychologist John B. Watson inspired him to enter graduate school at Harvard University in 1928. There his extraordinary mechanical skills allowed him to invent a series of devices for studying rat behavior. Ultimately one of those devices, subsequently known as the Skinner Box, gave him unprecedented control over ongoing behavior, summar-

ized in his first book, *The Behavior of Organisms: An Experimental Analysis* (1938).

Behaviorists inspired by the work of Russian physiologist Ivan Pavlov (1849–1936) had focused on relatively simple stimulus-response reflexes, whereas Skinner was able to show a high degree of orderliness in more common, fluid, everyday behavior, which Skinner called *operant behavior*. Skinner showed that a great deal of behavior that appeared to be spontaneous and voluntary was the product of a “history of reinforcement,” and he also showed how a *reinforcer* (a stimulus that strengthens the behavior it follows) could be delivered in optimal ways to alter future behavior. In a major breakthrough, Skinner showed that entirely new behaviors could quickly be taught simply by selectively reinforcing successive approximations to that behavior, a process he called *shaping*.

During the 1940s, 1950s, and 1960s, Skinner extended his laboratory discoveries to a number of practical human domains. During World War II he trained pigeons to guide missiles for the U.S. military (a project never fully implemented). In 1948 Skinner published a novel called *Walden Two*, in which he speculated about how a science of behavior might be used to create an ideal community. During the 1950s, in work with psychotic patients, he laid the foundations for modern *behavior therapy*, a term that was coined by his research team. He also invented sophisticated mechanical teaching machines and developed the first programmed textbook, advances which helped lead the way toward modern computer-aided instruction.

During the 1960s Skinner’s students and adherents guided by his numerous essays on education (brought together in 1968 in his book, *The Technology of Teaching*) developed successful reinforcement-based classroom management techniques, which were subsequently widely used in countries around the world. His work also inspired business professionals to develop new management techniques and incentive systems, and professionals working with developmentally disabled individuals were inspired to develop powerful new training and treatment techniques, which later became standard in virtually all treatment facilities for such individuals.

In its impact on education, Skinner’s work is similar to that of Edward L. Thorndike. In the late 1890s, while a graduate student at Harvard, Thorndike conducted animal experiments that convinced him of the enormous power of behavioral consequences, which led to Thorndike’s formulation of the Law of Effect, which remains influential in education in the early 2000s. Thorndike’s experiments had been relatively crude and were conducted in open chambers. Skinner eventually learned how to conduct such experiments in closed chambers, which eliminated distractions and the need for handling the animals, thus allowing

Skinner to determine much more precisely how behavior actually works. It was the precision in Skinner's research that helped lay the foundations for a true science of both animal and human behavior.

SOCIAL COGNITIVE THEORY

Social cognitive theory (SCT) refers to a psychological model of behavior that emerged primarily from the work of Albert Bandura (1977; 1986). Initially developed with an emphasis on the acquisition of social behaviors, SCT continues to emphasize that learning occurs in a social context and that much of what is learned is gained through observation. SCT has been applied broadly to such diverse areas of human functioning as career choice, organizational behavior, athletics, and mental and physical health. SCT also has been applied extensively by those interested in understanding classroom motivation, learning, and achievement (Pajares, 1996; Schunk & Zimmerman, 1994; 1998).

SCT rests on several basic assumptions about learning and behavior. One assumption concerns triadic reciprocity, or the view that personal, behavioral, and environmental factors influence one another in a bidirectional, reciprocal fashion. That is, a person's on-going functioning is a product of a continuous interaction between

cognitive, behavioral, and contextual factors. For instance, classroom learning is shaped by factors within the academic environment, especially the reinforcements experienced by oneself and by others. At the same time, learning is affected by students' own thoughts and self-beliefs and their interpretation of the classroom context.

A closely related assumption within SCT is that people have an agency or ability to influence their own behavior and the environment in a purposeful, goal-directed fashion (Bandura, 2001). This belief conflicts with earlier forms of behaviorism that advocated a more rigorous form of environmental determinism. SCT does not deny the importance of the environment in determining behavior, but it does argue that people can also, through forethought, self-reflection, and self-regulatory processes, exert substantial influence over their own outcomes and the environment more broadly.

A third assumption within SCT is that learning can occur without an immediate change in behavior or more broadly that learning and the demonstration of what has been learned are distinct processes. One reason for this separation is that SCT also assumes that learning involves not just the acquisition of new behaviors, but also of knowledge, cognitive skills, concepts, abstract rules, values, and other cognitive constructs. This division of learning and behavior is a shift from the position advocated by behavioral theories that defined learning stridently as a change in the form or frequency of behavior. It also means that students can learn but not demonstrate that learning until motivated to do so.

HISTORICAL ORIGINS OF SCT

Born in 1925, Albert Bandura was trained and began his career in the mid-twentieth century when explanations of human functioning, including classroom learning, were dominated by behavioral models advocated by researchers such as B. F. Skinner, Clark Hull, Kenneth Spence, and Edward Tolman. In this context, Bandura, along with his students and colleagues, initiated a series of studies designed to examine social explanations for why and when children displayed aggressive behaviors. These studies demonstrated the value of modeling for acquiring novel behaviors and provided initial evidence for the separation of learning and performance. They also indicated the importance of the learner's perceptions of the environment generally, of the person modeling a behavior specifically, and of the learner's expectations regarding the consequences of behavior. In doing so, findings from this systematic research contradicted assumptions within behavioral models that learning was the result of trial and error learning or that changes in behavior were due primarily to the consequences of one's own actions.

Children learn by observing others. JENNY ACHESON/RISER/GETTY IMAGES.

By the mid 1970s these studies helped form the foundation for what Bandura initially called observational learning theory and then later social learning theory (Bandura, 1977). This precursor to SCT established a viable model for understanding how people learned through observation of models. Additional work during this time expanded aspects of the theory dealing with abstract modeling, language, and conceptual learning. In the years that followed, SCT continued to evolve, spurred by the work of Bandura and his colleagues stressing the processes of goal setting, self-efficacy, and self-regulation. The evolution of SCT also drew ideas from information processing models of psychological functioning to describe the cognitive processes that mediate learning. Ultimately, Bandura noted in the preface to his 1986 treatise, *Social Foundations of Thought and Action: A Social-Cognitive Theory*, that, in an effort to be inclusive of these more motivational and cognitive processes, he was using the label “social cognitive theory” rather than social learning to describe his framework. Throughout this book, Ban-

dura describes the philosophical and conceptual foundation for SCT and reviews empirical evidence for its main components. Hence, it provides a concrete milestone for the birth of contemporary SCT. Since that time, SCT has continued to grow and expand especially with regard to the work on self-efficacy, self-regulation, and agency (Bandura, 1997; 2001; Zimmerman, 2000).

CORE CONCEPTS WITHIN SCT

SCT integrates a large number of discrete ideas, concepts, and sub-processes into an overall framework for understanding human functioning. Five of the central concepts are described below. For a more complete explanation of SCT, readers are directed to works by Bandura and to the relevant chapters within textbooks on learning.

Observational Learning/Modeling. From its inception one core premise within SCT has been that people learn through observation. This process is also described as vicarious learning or modeling because learning is a result of watching the behavior and consequences of models in the environment. Although observational learning is dependent upon the availability of models, who or what can serve this role is defined broadly. Live demonstrations of a behavior or skill by a teacher or classmate, of course, typify the notion of modeling. Verbal or written descriptions, video or audio recordings, and other less direct forms of performance are also considered forms of modeling. There also distinctions among different types of models. Mastery models are proficient when demonstrating a skills, whereas coping models struggle, make mistakes, and only eventually show proficiency. Abstract modeling occurs when the skill or knowledge being learned is conveyed only indirectly, and cognitive modeling occurs when a model verbalizes her thoughts while demonstrating a cognitive process or skill.

According to SCT, observational learning of novel behaviors or skills is dependent on four inter-related processes involving attention, retention, production, and motivation. Attentional processes are critical because students must attend to a model and the relevant aspects of behavior in order to learn. Retention refers to the processes necessary for reducing and transforming what is observed into a symbolic form that can be stored for later use. Production processes are necessary when students draw on their stored codes and make an effort to perform what they have observed. Finally, motivational processes are key for understanding why students engage in the prior sub-processes, including whether they ever attempt to use or recreate the new skills they have observed. Each of these processes, furthermore, are affected by factors such as the developmental level of the learner and characteristics of the model and modeled behavior.

Beyond new learning, modeling is also important for understanding when or why previously learned behaviors are exhibited. Students' may inhibit their engagement in a behavior if they observe a model suffer consequences they would prefer to avoid. For instance, if a teacher glares at one student who is talking out of turn, other students may suppress this behavior to avoid a similar reaction. In a related fashion, students may disinhibit or engage in a behavior they had initially suppressed when they fail to see any negative consequences accrue to a model. For example, students may refrain from shouting out answers unless they are called upon only until they see others do so without repercussions. Finally, through a process labeled response facilitation, models can simply prompt others to behave in known ways.

Outcome Expectations. Outcome expectations reflect individuals' beliefs about what consequences are most likely to ensue if particular behaviors are performed. For instance, children may believe that if they get a hit during a baseball game the crowd will cheer, they will feel good and will be admired by their teammates. These beliefs are formed enactively through students' own past experiences and vicariously through the observation of others. Outcome expectations are important in SCT because they shape the decisions people make about what actions to take and which behaviors to suppress. The frequency of a behavior should increase when the outcomes expected are valued, whereas behaviors associated with unfavorable or irrelevant outcomes will be avoided.

Perceived Self-efficacy. Self-efficacy also has emerged as a prominent and influential concept within SCT. Self-efficacy reflects individuals' beliefs about whether they can achieve a given level of successful at a particular task (Bandura, 1997). Students with greater self-efficacy are more confident in their abilities to be successful when compared to their peers with lower self-efficacy. Self-efficacy has proven useful for understanding students' motivation and achievement in academic contexts. Higher levels of perceived self-efficacy have been associated with greater choice, persistence, and with more effective strategy use (Pajares, 1996).

Consistent with the tenets of SCT, self-efficacy is viewed as a product of individuals' own past performances, the observation and verbal persuasion of others in the environment, and individuals' on-going physiological state (Bandura, 1997). Rather than directly affecting their self-efficacy, however, these sources of information are weighed and filtered through a process known as cognitive appraisal. For instance, a prior failure may not be detrimental to self-efficacy if students believe there was some no-longer relevant reason for the poor performance (e.g., prior sickness). Interventions based on SCT and designed to increase self-efficacy in school-aged children have proven effective (Pajares, 1996).

Goal Setting. Goal setting is another central process within SCT (Bandura, 1986; Schunk, 1990). Goals reflect cognitive representations of anticipated, desired, or preferred outcomes. Hence, goals exemplify the agency view within SCT that people not only learn, they use forethought to envision the future, identify desired outcomes, and generate plans of action. Goals are also closely related to other important processes within SCT. For instance, models can provide goals in the form of specific behavioral outcomes or more general standards for acceptable levels of performance. Goals also are intricately related to students' outcome expectations and their perceived self-efficacy. Goals are a function of the outcomes students expect from engaging in particular behaviors and the confidence they have for completing those behaviors successfully. Finally, goals are an important prerequisite for self-regulation because they provide objectives that students are trying to achieve and benchmarks against which to judge progress.

Self-regulation. Research on self-regulation or, when applied to academic contexts, self-regulated learning, blossomed in the 1980s and continued into the early 2000s to expand. Explanations for students' management or control of their own learning behaviors have arisen from within many distinct theoretical perspectives (Zimmerman & Schunk, 2001). Many of the most common models, however, have strong roots in SCT. SCT models of self-regulation assume that self-regulation is dependent on goal setting, in that students are thought to manage their thoughts and actions in order to reach particular outcomes (Schunk, 2001; Zimmerman, 2000). SCT views of self-regulation initially emphasized three sub-processes (Bandura, 1986; 1991). Self-observation reflects students' ability to monitor or keep track of their own behaviors and outcomes. Self-judgment is the process through which students' evaluate whether their actions are effective and allow them to make progress toward their goals. Finally, self-reaction occurs when students' respond to the evaluations they have made by modifying their behavior, rewarding it, or discontinuing it.

Self-regulation is a prominent and increasing aspect of SCT that exemplifies the underlying assumptions regarding agency and the influence of personal factors on behavior and the environment. As noted above, self-regulation is also dependent on other processes within SCT, including goal setting and self-efficacy. Unless students have goals and feel efficacious about reaching them, they may not activate the processes needed for self-regulation. Modeling can also affect students' self-regulated learning. The skills needed to manage one's behavior, as well the beliefs and attitudes that serve to motivate self-regulation, can be obtained through modeling.

TELEVISION: EDUCATOR'S FRIEND OR FOE?

From its inception, television has been considered a behavioral stimulus (Vos Post, 1995). Factors that impact research on the influence television has on behavior include socio economic status and rural versus urban settings, as well as factors that are pertinent to the nature and culture of the local society. Is a "shoot 'em up" cops and robbers television programming any more violent than a news report of a suicide bomber in the Middle East? Should children be shielded from viewing either or both of those programs on television? The social cognitive theory of behavior learned through observation expounded by Bandura (2001) has been related to television as well as to the classroom and home environments. Young children are particularly unable to discriminate between the fiction of television and real life. Research shows that they are likely to apply the aggressive behaviors they have seen on television to the playground as early as nursery school age. According to Ortiz (2007), they internalize behaviors that they observe even though they have not experienced them directly.

In 1995 Aronson defined aggression as "behavior causing harm or pain." In that same year, Vos Post added that "we still have no widely accepted, clear cut, and scientific definition for either the aggressive acts on television or those purportedly caused by television by its audience." In the mid 1990s researchers counted an average of 18 acts of aggression per hour during the Saturday morning cartoons that continue in the 21st century to be popular with young children. George Gerbner has reported that violent acts take place five or six times per hour during prime time and Saturday morning television. In addition, eight of ten television programs include some sort of violence.

Vos Post (1995) stated that programming on U.S. television was no more aggressive than it had been historically. He went on to report that television programming in Japan had a much higher level of violence than television programming in the United States. However, there are considerably lower rates of aggression in Japan than in the United States, which contradicts the argument that aggressive behavior is learned or encouraged by viewing violence on television.

When Bandura's social cognitive theory, which suggests that children learn through observation, is extended to television viewing, it would seem to indicate

that children would learn aggressive behavior through observation of violence on television. It also means that if children observe positive behaviors in television programming, they should emulate those behaviors as well. Bandura's theory states that when children see behavior modeled, they will accept it and use it when they deem it appropriate. It also explains the need for positive role models on television for children.

According to Bandura's social cognitive theory, when children see family members or friends working together on a television situation comedy to resolve a problem, it follows that they will try to resolve problems with their own family members or friends peacefully, by working together, instead of fighting with them. Research on the results of this type of modeled behavior is reported to be difficult, with inconclusive results.

According to Hoffner (1996), Bandura's theory of behaviors learned by observation means that young viewers have to identify with the characters to model either pro social or violent behavior. In other words, if a child observes television characters that she or he perceives as being similar to herself or himself, that child will be more likely to behave in a manner similar to those characters.

Educational programming is based on Bandura's theory of modeled behavior. To be effective with pro social behaviors, television programmers have to conduct extensive research and make sure characters and events portrayed in their shows have a relation to real world situations. They also have to carefully create characters who are positive, with good results from their actions; negative, with undesirable results from their actions; and transitional, who start the show as negative characters but change because of decisions made and actions taken, so they become positive role models by the end of the show.

Violent acts in regular television programming have more of an effect on children's behavior than sports programming. The results of research on the effect that violence on television has on students generally are in agreement that children who observe violence in prime time television or on Saturday morning children's shows that do not include sports programming will behave aggressively whether or not they had were pre disposed to behave aggressively.

A real concern with the effects of television violence and aggressive behavior learned by observation of incidents of violent programming is that this learning has been proven to continue through adolescence and into adulthood. Vos Post (1995) concluded: "Not only because television violence is a reality, and aggression is a fact of life, but because an effective social psychology understanding of the relationship between television and behavior may help to not only reduce socially unacceptable aggression, but may actually enable us to increase socially desirable effects."

IMPLICATIONS FOR CLASSROOM INSTRUCTION

One strength of SCT is that it provides a clear foundation for classroom interventions designed to improve students' learning. In this section, several general implications for instruction derived from the key concepts described above are described. More complete treatments of the instructional implications of SCT readers are available elsewhere (e.g., Linares et al., 2005; Paris & Paris, 2001; Zimmerman, Bonner, & Kovach, 1996).

Observational Learning/Modeling. The most basic instructional implication of SCT is that students should be provided frequent access to models of the knowledge, skills, and behaviors they are expected to learn. For example, teachers should model the behaviors and cognitive processes they want students to learn. Effective instruction, moreover, should include multiple types of models (e.g., teacher, peers, parents) and various forms of modeling (e.g. cognitive, verbal, mastery, coping). The inhibitory and disinhibitory effects of modeling, further, necessitate that educators administer rewards and punishments in a careful and consistent manner.

More specifically, instruction based on SCT should support students' engagement in each of the four sub-processes of observational learning. Students' attention can be increased by using models that are viewed as competent, prestigious, and similar to themselves. Students also pay closer attention when the skill or material being demonstrated is considered more personally relevant or interesting. Instruction should support students' retention by facilitating the creation of verbal labels or images through the use of mnemonics, graphic organizers, or other similar learning strategies. Opportunities for

rehearsal, both in the form of repeated exposure to models and in the form of time to reflect on the material or skills also assist retention. The effective use of models depends on providing students multiple opportunities to practice the behaviors or skills they have observed. This process will be improved if students are provided feedback about their efforts that is specific, more immediate, and insightful about what the learner is doing well and what needs improvement. Teachers should support the motivational aspects of observational learning through the purposeful use of rewards and punishments. These consequences, further, should shape students' behavior when they are provided either to the learner or to a model. To improve motivation, teachers should also model attitudes that they want students to adopt such as enthusiasm or interest in the material.

Outcome Expectations. Instruction should help students to see that classroom learning and the demonstration of that learning leads to personally valued or important outcomes. Students must believe that, if they complete learning tasks successfully, the outcomes they achieve are meaningful, useful, or worthy of the effort necessary to reach them. To encourage these beliefs, teachers should create lessons that emphasize real-world applications and the relevance of material to students' own lives. Decontextualized instructional practices that obfuscate the benefits of learning should be avoided.

Perceived Self-Efficacy. Students will be more active, effortful, and effective learners when they are confident in their ability to complete academic tasks successfully. Hence, instruction should be designed in a way that helps them to develop and sustain their self-efficacy for learning. Most simply, tasks should be moderately challenging so

that students do well and make progress when providing reasonable effort. Teachers should ensure that students have the prerequisite knowledge and strategies needed to be successful at more complex and rigorous tasks. In this way, students will develop a pattern of success that fosters positive levels of self-efficacy. Self-efficacy can also be improved when students are exposed to peer models who initially struggle but who ultimately are able to complete tasks effectively (i.e., coping models). Finally, teachers can make direct statements to learners or models as a way to boost their confidence. Such statements, however, must be credible or they will be discounted or ignored by learners.

Goal Setting. Instruction should help students to set effective goals by addressing the properties found in the most effective goals (Schunk, 1990). Instructional practices should promote students' efforts to set attainable goals that are clear, specific, and moderately challenging. In order to show progress and to maintain self-efficacy, learning goals should be attainable with moderate levels of effort. These goals will also reduce disappointment and frustration that students might feel if they fail to reach their goals. Specific goals are more effective than general or vague goals in spurring students to action and in guiding their behavior. Students should have both distal and more short-term goals for their learning in school. However, proximal goals are more effective at guiding behavior because they allow for more immediate feedback about progress. Finally, goals that students set or endorse themselves have a bigger impact on their behavior than goals that are assigned. Hence, instruction should help students develop the ability and willingness to form their own academic goals.

Self-Regulation. According to SCT, all students should be supported in their efforts to be self-regulated learners. In addition to fostering self-efficacy and effective goal setting, teachers should help students become skilled at self-observation, self-judgment, and self-reaction (see Zimmerman et al., 1996). Teachers can promote self-observation by helping students learn how to monitor different aspects of their academic behavior. Practices such as journal writing, checklists, and time for self-reflection help students develop these skills. For self-judgment, students must learn how to evaluate their performance in light of the goals or standards they have set. Teachers can facilitate this process through modeling and by supporting students' own efforts to compare their performance to both absolute and normative standards. Teachers should also help students see the value and relevance of the standards in order to encourage their self-judgment. The self-reaction process depends on students' ability to respond adaptively both when they are making progress and when they are not. For the former,

instructional practices should assist students in learning how to self-administer reinforcements for their own efforts using both concrete and internal rewards. For the latter, instruction should support students in their efforts to evaluate and modify their learning strategies in order to improve progress. As with all skills, students can develop these self-regulatory abilities vicariously and with guided opportunities to practice them firsthand.

SOCIAL COMPARISONS

Social comparisons are carried out when a person relates abilities, opinions, or other characteristics of one person or group to abilities, opinions, or other characteristics of another person or group. In academic settings, social comparisons occur (intentionally or unintentionally), for example, when a student compares his own exam grade with the grade of a class mate or when a teacher thinks of the best or worst students in mathematics in his class. Referring to educational theory and research, social comparisons are important and valid predictors of students' self-evaluations and achievement behavior.

FESTINGER'S THEORY OF SOCIAL COMPARISON

The study of social comparison was initiated by the social psychologist Leon Festinger (1954). In his model, Festinger outlines the central processes underlying the formation of the beliefs about one's own abilities and opinions held by a person. Festinger hypothesizes that a motive for self-evaluation triggers social comparisons, in particular when objective means are not available. Following Festinger, people tend to use similar other persons as comparison targets to maximize the information resulting from comparisons. Goethals and Darley (1977) defined similarity in terms of related attributes. Therefore, comparisons are more useful when the comparison target shares relevant attributes (for example, gender or age) with the person carrying out the comparison. Comparing one's math performance with the math performance of a same age student is much more informative than comparing the math performance with a younger or older student.

UPWARD AND DOWNWARD COMPARISONS

Studies on spontaneous comparisons using diary methods revealed insight in the occurrence of social comparisons in daily life. According to Wheeler and Miyake (1992) situations such as school exams actually encourage social comparisons.

When students are free to choose a particular classmate as a comparison target, the majority prefers slightly

higher achieving classmates. This finding corresponds to the "unidirectional drive upward" hypothesis. Such comparisons with slightly better classmates are called upward comparisons. They often seem to be caused by the aspiration to get hints from analyzing the work of better-off students. Therefore, a self-improvement motive may trigger upward comparisons.

If a student chooses to compare with a lower achieving classmate downward comparisons are carried out. Downward comparisons often seem to be caused by the motive to feel good or better; self-enhancement or self-protection motives may trigger downward comparisons.

The frequency of upward and downward comparisons is affected by performance level and pre-comparison affect. Good performance and positive mood predict downward social comparisons whereas poor performance and negative mood predict upward social comparisons (Blanton, Buunk, Gibbons, and Kuyper, 1999).

HOW SOCIAL COMPARISON INFLUENCES STUDENTS' SELF BELIEFS

If a student gets better grades than others, and feels to be more competent in a particular subject in relation to other students, relatively positive self-evaluations may be the consequence. Thus, good grades and downward comparisons lead to a relatively high academic self-concept in that subject. If a student gets worse grades than others, and feels to be less competent in a particular subject in relation to other students, relatively negative self-evaluations may be the consequence. Therefore, bad grades and upward comparisons lead to a relatively low academic self-concept in that subject.

However, each comparison direction may reveal opposite consequences as well. On the one hand, upward comparisons may boost self-concepts when individuals believe that they can improve their own performance and become as good as the comparison target. On the other hand, downward comparisons may reduce self-concepts when people believe that they may become as worse as their comparison target.

Researchers have to distinguish social comparison effects on different kinds of self-beliefs. At first, social comparisons are relevant for the self-concept formation as described above. In addition, they are relevant for more affective evaluations such as self-esteem. For example, in the Wheeler and Miyake study, the direction of comparison had an impact on the affective reaction upward social comparisons reduced, and downward social comparisons enhanced subjective well-being.

Social comparisons are less important for self-efficacy measures which include different questions concerning specific tasks ("How many of these particular

tasks will you solve within 30 minutes?”) Answering these questions does not necessarily require social comparison processes but prior experience with similar tasks.

HOW SOCIAL COMPARISON INFLUENCES STUDENTS' PERFORMANCE

Social comparisons not only influence students' self-concepts but also improve their performance. Blanton et al. (1999) longitudinally investigated the effects of comparison processes on academic performance. They asked students to nominate a particular classmate with whom they typically compared their grades. One of the central results was that students, on average, preferred upward comparisons which improved their grades in longitudinal analyses controlling for prior grades.

BIG FISH IN A LITTLE POND EFFECT

The big-fish-little-pond effect (BFLPE) is based on students' comparisons of their own ability or performance with the abilities of their classmates. This social comparison process leads to a lower self-concept when the class level is high and to a higher self-concept when the class level is low. Therefore, two students with equal performance in a domain may develop different self-concepts when they belong to different classes with different performance levels.

Whereas social comparison research usually analyses the consequences of comparisons with particular other persons, research on the BFLPE assumes that students compare their own ability with the class or school level. Marsh, Trautwein, Lüdtke, and Köller (2007) assume that such a generalized other serves as an (unintentionally chosen) comparison target leading to a self-concept decrease following upward comparisons (small fish in a big pond) or to a self-concept increase following downward comparisons (big fish in a little pond).

Moreover, Marsh et al. (2007) compared results based on comparisons with a generalized other (class-average achievement) and comparisons with a specific classmate. Both sources of social comparison information contributed negatively to self-beliefs with regard to math ability. Selecting higher achieving classmates as comparison targets as well as attending high performing classes reduced self-beliefs. Comparing downward with worse performing classmates as well as attending a low performing class increased self-beliefs.

OTHER TYPES OF COMPARISONS

Clearly, a lot more comparisons take place in schools; students (as well as teachers) can compare their performance, motivation, effort, and other characteristics to each standard they want. Following Skaalvik and Skaalvik

(2002), students use multiple external and internal frames of reference while making self-judgments. They may compare their achievement with goals and aspirations, with effort in those subjects, or with other external standards such as school grades and class rankings.

According to the Internal/External-Frame-of-Reference model (I/E model, Marsh, 1986), students compare their levels of academic ability using two different, but connected, frames of reference: internal (dimensional) and external (social) comparison processes. Within the external frame of reference, students conduct social comparisons: that is, they compare their accomplishments with those of their classmates. If their verbal achievement is higher than their classmates', their verbal self-concept will also be higher. Because achievements in school subjects typically are positively correlated, it would seem reasonable to assume that these social comparison processes will lead to domain-specific self-concepts that are also positively correlated.

Processes of internal or dimensional (Möller & Köller, 2001a) comparison have been drawn on to explain the domain-specificity of academic self-concepts and the often very low correlations observed between verbal and math self-concept. According to this internal frame of reference, students evaluate their achievements in any given subject in relation to their own achievements in other subjects. Therefore, talented students may develop an average self-concept in their worst subject, even though their performance in this subject is well above the average performance of their peers. Hence, social and dimensional comparisons affect the development of domain-specific self-concepts. Based on external comparisons with one's classmates' achievements in mathematics, low math ability tends to lead to low math self-concept. Based on internal comparisons between one's own achievement in mathematics and one's achievement in verbal domains, low math ability seems to lead to an increase in verbal self-concept (see the meta-analyses by Möller, Pohlmann, Köller & Marsh, 2007).

EDUCATIONAL IMPLICATIONS OF SOCIAL COMPARISON RESEARCH

Social comparisons matter in different ways. Teachers can affect the types of social comparisons carried out by themselves and their students. Teachers who overly compare the low performances of their poorer students to the performances of their better students may further reduce the poorer students' self-concepts and self-esteem. In particular, poorer students who did not expect to be able to improve their performance significantly may suffer in a highly competitive class. It may be more useful for teachers to compare students' performance intra-individually and over time. Such temporal comparisons should outline

the progress even poorly performing students reveal. Teachers' encouraging comments particularly following academic failure may reduce the amount and importance of unfavorable social comparisons, which could protect poorly achieving students' self-beliefs and motivation to a certain degree.

Moreover, teachers may use the positive effects of upward comparisons with slightly better-off classmates. If a student is convinced that he is able to reach the comparison target's performance level, it is useful to analyze the better performance of a classmate in order to improve his own performance. In particular, within cooperative learning settings the positive effects of social learning may be fostered when students are taught to cooperate and not to compete.

SOCIAL GOALS

Social goals are increasingly being appreciated as important to understanding engagement and achievement in school. In general, social goals refer to what students are

focused on and trying to accomplish with their peers. Three main approaches have been used to investigate students' social goals in relation to academic adjustment: a content approach, an achievement goal approach, and a hybrid social-academic goal approach.

DIFFERENT CONCEPTUALIZATIONS OF SOCIAL GOALS

First, social goals have been conceptualized as how often students focus on or try to do various things with their peers (e.g., have fun, follow rules). This approach is often referred to as a goal content approach and assumes students strive for certain outcomes that direct their behavior (Anderman & Anderman, 1999; Ford, 1992; Jarvinan & Nicholls, 1996). Some of the main social goals that have been identified within this approach are: responsibility goals, prosocial and intimacy goals, popularity goals, and dominance goals. Responsibility goals refer to a focus on conforming to the social and moral rules, meeting obligations, and keeping commitments. Prosocial goals refer to forming friendships as well as helping, sharing, and cooperating with peers. Intimacy goals are similar to prosocial goals but focus more specifically on establishing intimate friendships characterized by mutual support and disclosure of thoughts and feelings. Popularity goals refer to a focus on establishing high social status characterized by visibility and prestige within the larger peer group at school. Dominance goals refer to a focus on having power over peers characterized by getting peers to comply with one's wishes and instilling fear in peers.

Second, social goals have been conceptualized as distinct orientations toward social competence and linked to adjustment in the classroom (an achievement goal approach, encompassing development and demonstration goals; Erdley, Cain, Loomis, Dumas-Hines & Dweck, 1997; Host, Finney, & Barron, 2007; Ryan & Shim, in press). A social development goal concerns a focus on developing social competence with peers. The focus is on learning new material and skills, growth, and improvement. Success would be judged by whether one is improving social skills, deepening the quality of relationships, or developing one's social life in general. A social demonstration-approach goal concerns a focus on demonstrating social competence and gaining from peers positive judgments that one is socially desirable. A social demonstration-avoid goal concerns a focus on demonstrating that one does not lack social competence. The focus is on avoiding doing something that would incur negative judgments from peers and indicate social undesirability. With both social demonstration goals, attention is focused on the appearance of the self, especially in relation to others. For a social demonstration-approach

goal, success is garnering positive feedback from peers, social prestige, and having a good reputation compared to others (e.g., being popular or seen as important), and for a social demonstration-avoid goal, success is avoiding negative judgments from peers compared to others and lack of a reputation as socially awkward or ineffective (e.g., not being seen as a loser or *geek*). These social achievement goals are analogous to those identified in other domains, although described with different terms (e.g., *mastery* and *performance* in the academic domain).

Third, social goals have been conceptualized as the social reasons students have for the pursuit of academic achievement (a hybrid social-academic goal approach; Dowson & McInerney, 2001; Urdan & Maehr, 1995). Social goals identified in this approach are affiliation goals, approval goals, concern goals, and responsibility goals. A social affiliation goal is the desire to do well academically to enhance one's sense of belonging in the group. A social approval goal is the desire to do well academically to gain approval from others (parents, teachers, or peers). A social concern goal is the desire to do well academically so one can help or assist others in their personal or academic development. A social responsibility goal is the desire to do well academically to maintain an interpersonal commitment, fulfill one's obligation, or follow the social/moral rules.

SOCIAL GOALS AND ADJUSTMENT IN SCHOOL

Research on social goals has provided insight into students' academic adjustment in school. Social goals have implications for academic adjustment via the behaviors as well as the types of social relationships they promote (Wentzel, 2005). Responsibility and prosocial goals have been found to be positively related to academic engagement and achievement (e.g., Wentzel, 1996). Similarly, intimacy goals have been found to be positively associated with positive attitudes toward school (Anderman, 1999), engagement and achievement (Kiefer & Ryan, in press). Striving for responsibility, prosocial outcomes, and intimacy with peers are positive orientations towards social relations that also facilitate academic adjustment in the classroom. In contrast, popularity goals are less adaptive for students' academic adjustment. The pursuit of popularity goals has been found to be related to negative attitudes about school (Andermann, 1999) and disengagement in the form of help avoidance (Ryan, Hicks & Midgley, 1997). However, popularity goals are often found to be not related to engagement and achievement at school (Kiefer & Ryan, in press). Finally, social dominance goals seem the most detrimental for academic adjustment as they are negatively associated with effort, positively associated with disruptive behavior, and negatively associated with grades in school (Kiefer & Ryan, in press).

When students are focused on establishing power over their peers (making others do what they want and establishing their toughness) they are more likely to act in ways that disrupts the class and less likely to put effort into their schoolwork, and not surprisingly this undermines their achievement.

The social achievement goal approach to social goals has found that a social development goal is adaptive for classroom adjustment whereas social demonstration-approach and avoid goals are maladaptive, although for different reasons. A social development goal has been associated with prosocial behavior with peers in the classroom (e.g., cooperation and sharing). A social development goal has been negatively associated with disruptive and aggressive behavior (Ryan & Shim, in press).

A focus on developing social competence seems to be a positive orientation towards the social world that sets in motion adaptive beliefs and behaviors in the classroom. In contrast, a social demonstration-approach goal has been found to be positively associated with disruptive and aggressive behavior and negatively associated with prosocial behavior with peers in the classroom. A social demonstration-avoid goal has been found to be positively associated with anxious solitary behavior and worry (Ryan & Shim, in press). Thus, a focus on demonstrating social competence seems to lead to maladaptive behavior in the form of inappropriate actions that are active or external to the student. A social demonstration-avoid goal also has drawbacks but is manifested in actions that are more passive or internal to the student.

Some research suggests that it may be important to consider the fact that students may pursue multiple social achievement goals in the classroom. For example, a social development goal was found to ameliorate the positive relation between a social demonstration-approach goal and aggressive behavior (Ryan & Shim, in press). This suggests that an additional benefit of a social development goal is that it can minimize the aggressive behavior that is associated with a social demonstration-approach goal.

Concerning the social-academic hybrid approach to goals, qualitative research has found that these social goals (affiliative, approval, concern, and responsibility) are intertwined with students' comments about their affect, engagement, and achievement in school (Dowson & McInerney, 2001). A quantitative study found these social-academic goals to be distinct factors from their cognitive and metacognitive strategies for their work (Dowson & McInerney, 2004). An interesting area of future research will be further investigation of the relation of the relation of these social-academic goals to engagement and achievement.

IMPLICATIONS FOR TEACHERS

Teachers need to attend to students' social goals as research has found them to be important to engagement and achievement. When students are not successful in the classroom, part of the explanation may be related to their social goals. Teachers should encourage adaptive social goals (e.g. pro-social and development goals), redirect maladaptive social goals into more appropriate ones (e.g., steer from dominance goals to leadership goals) and vary the opportunities and nature of academic tasks so that social goals do not compete with or undermine academic goals and behaviors (e.g., seating and grouping of students; opportunities to collaborate with peers).

In sum, there are three key perspectives on social goals: (a) a goal content approach, (b) an achievement goal approach, and (c) a hybrid social-academic goal approach. For theory and research related to the social goal content perspective, see Martin Ford (1992), Kathryn Wentzel (1996), and Lynley Anderman (1999). For theory and research related to the achievement goal approach, see Carol Dweck (e.g., Erdley et al., 1997), Allison Ryan (Ryan & Shim, in press), Jeanne Horst (Horst, Finney, & Barron, 2007), and Andrew Elliot (Elliot, Gable, & Mapes, 2006). For theory and research related to a hybrid social-academic goal approach, see Tim Urdan (Urdan & Maehr, 1995) and Martin Dowson and Dennis McInerney (2001; 2004).

SOCIAL SKILLS

Children's social skills are important for early school success and later adjustment. Research has documented that children without adequate social skills are at risk for difficulties including peer rejection, behavior problems, and poor academic achievement. Moreover, recent research shows disturbing rates of expulsion in preschool and kindergarten, which has fueled efforts to promote these skills (Gilliam & Shahar, 2006). Broadly speaking, social skills describe how children navigate social and learning contexts and can be conceptualized as including interpersonal skills and learning-related skills. *Interpersonal skills* refers to the ability to perform competently in social situations, including interacting positively with others, cooperating, sharing, and respecting peers. Research has found that interpersonal skills are important for peer acceptance and social adjustment throughout childhood and adolescence (Masten et al., 2005).

In contrast to interpersonal skills, *learning-related skills* are important for learning and achievement in childhood and adolescence. These skills include self-regulation and social competence (e.g., cooperation, independence, and responsibility) on classroom tasks and in learning situations. There is strong evidence that

learning-related skills predict academic achievement in kindergarten and throughout elementary school (McClelland, Acock, & Morrison, 2006). Aspects of learning-related skills are also important for achievement in adolescence (Duckworth & Seligman, 2005).

Although interpersonal skills and learning-related skills fall under the broad social skills construct, they are separate but related constructs with differing relations to outcomes in childhood and adolescence. Whereas interpersonal skills have been mostly linked to children's social development, learning-related skills have been related to doing well in classroom settings and to academic success.

PROCESSES THAT SUPPORT DEVELOPMENT OF SOCIAL SKILLS

One of the most important influences in early childhood is neurological maturation in the areas of the brain that help children control, direct, and plan their actions. Evidence from brain research shows these skills are associated with particular patterns of frontal lobe activity, specifically in the prefrontal cortex (Blair, 2002). Rapid development in the prefrontal cortex between ages 3 to 6 means the preschool period is a crucial time for acquiring social skills (Shonkoff & Phillips, 2000). Children's social skills vary widely, however, which may be related to differences in prefrontal cortex development, as well as other individual and environmental factors throughout childhood and adolescence (Calkins, 2004). For example, recent research has suggested that growing up in poverty is related to increased stress levels for young children, which can alter brain development in ways that are linked to social skill and self-regulation difficulties (Dearing, Berry, & Zaslow, 2006; Gunnar, 2006).

Child temperament, including children's level of reactivity and regulation, also plays a significant role in the social development of children and adolescents. One aspect of temperament, effortful control, helps children regulate their emotions and behavior, and has emerged as being especially important for self-regulation and social competence (Rothbart & Rueda, 2005).

A large body of research has also examined the vital role that parents play in the development of their children (Collins, Maccoby, Steinberg, Hetherington, & Bornstein, 2000). Although many aspects of parenting are important for children's development, parental warmth and sensitivity have emerged as two of the most salient predictors of children's social development (NICHD Early Child Care Research Network, 2006).

The quality of the parent-child attachment relationship also predicts children's social skills. A number of studies have found that having a secure attachment with a parent allows children to express emotion effectively and develop strong self-regulatory skills. Moreover, studies of

attachment highlight the importance of the child's behavior, including reactivity and responsiveness, in helping to shape the attachment relationship (Calkins, 2004).

NORMATIVE DEVELOPMENTAL CHANGES IN SOCIAL SKILLS

From early childhood through adolescence, social skill development occurs through a reciprocal and bidirectional relationship between a child's individual characteristics (e.g., temperament) and the environment (e.g., parent warmth and sensitivity, family factors, and peers). Children begin developing social skills within the context of the parent-child attachment relationship (Rubin, Bulkowski, & Parker, 2006). It is from this relationship that children learn to read emotional cues, regulate their own emotions and behavior, and incorporate the responses of their parents into their own experiences with people and situations; a process known as social referencing (Thompson & Lagattuta, 2006). From observing family members, children learn appropriate social rules and behaviors, which they apply to interactions outside of the family.

In early childhood, children have exposure to other children in childcare settings. As toddlers, children engage primarily in solitary play, but interactions with other children increase with age. Positive interactions with peers help children develop interpersonal skills, communication skills, emotional understanding/regulation, the ability to control aggressive behaviors, and early learning-related skills. A number of developmental changes occur in early childhood that also facilitate the development of social skills, including a significant increase in vocabulary (Thompson & Lagattuta, 2006) and brain maturation in the prefrontal cortex (Blair, 2002). These developmental changes lead to an improved ability to communicate and regulate feelings and behaviors. Children also begin to develop empathy and gain an understanding of the feelings, desires, and beliefs of their peers; skills which continue to impact social development throughout childhood and adolescence.

Friendships become increasingly important in middle childhood and adolescence, especially for the development of social skills. As children improve their ability to understand the emotions of others, they build increasingly mature friendships and strengthen their interpersonal and learning-related skills. Children and adolescents who have difficulty empathizing or self-regulating have few positive social interactions and are likely to be rejected or neglected by peers, which can significantly impact social well-being and academic outcomes (Rubin et al., 2006).

SOCIAL SKILLS DEVELOPMENT AND SCHOOL ADJUSTMENT

A large body of evidence supports the role that children's social skills (including interpersonal skills and learning-related skills) play in social and academic success. In general, children's interpersonal skills have been linked to social outcomes whereas learning-related skills have predicted academic success. Interpersonal skills are especially important for social adjustment in childhood and adolescence. For example, one study found that poor interpersonal skills (e.g., externalizing problems) in childhood, predicted academic problems in adolescence, which in turn led to internalizing problems in adulthood (Masten et al., 2005).

There is also strong evidence that learning-related skills predict early academic achievement (McClelland et al., 2006). For example, one study found that prekindergarteners who had difficulty using learning-related skills to complete goal-directed activities scored lower on a standardized cognitive achievement measure. These children also exhibited more risk factors, such as family problems, lower parental education, and behavioral or emotional problems (Bronson, Tivnan, & Seppanen, 1995). Another study found that the gains in learning-related skills, specifically self-regulation, predicted gains made in early literacy, vocabulary, and math skills over the prekindergarten year in a diverse sample of children across two sites in the United States (McClelland et al., 2007).

Other research in elementary school has demonstrated that kindergarten learning-related skills significantly predicted reading and math achievement between kindergarten and sixth grade, and growth in literacy and math from kindergarten to second grade (McClelland et al., 2006). Finally, in one recent study, aspects of learning-related skills, such as self-discipline, were stronger predictors of academic performance than intelligence test scores in adolescents (Duckworth & Seligman, 2005).

A number of studies also support relations between interpersonal skills and learning-related skills for children's school adjustment. For example, research has shown that children's self-regulation positively relates to social competence, and that strong self-regulation can buffer otherwise negative outcomes (Lengua, 2002). Taken together, research suggests that promoting interpersonal skills and learning-related skills in young children and adolescents is one way to ensure strong social and academic skills.

ASSESSING STUDENTS' SOCIAL SKILLS

A variety of methods are used to assess children's social skills. When determining a method of assessment, it is essential to select instruments that are reliable, valid, and feasible given cost and time limitations. It is also critical

to choose measures that are appropriate for the age, developmental stage, and special needs of the target population (McClelland & Scalzo, 2006).

Naturalistic observations are one of the best methods for assessing interpersonal and learning-related skills. Typically, observations are conducted at school where there is ample opportunity to observe children interacting within social and learning environments. Observers should be objective and trained in how to code and record the frequency, duration, and interval of behaviors that are being assessed. Although observation provides a rich source of information, it is time-consuming and most useful for initial assessments rather than ongoing evaluation (McClelland & Scalzo, 2006).

Behavior rating scales also measure interpersonal and learning-related skills, but are less time-intensive and more cost effective than observations. They have high levels of reliability and validity and can be used to assess children who are too young to report their own behaviors. They do not, however, provide information about the antecedents and consequences of behavior.

Structured and unstructured interviews provide useful information regarding a child's social context, although they lack reliability and validity. Another limitation of interviews is that children often provide biased responses as they can be suggestible and influenced by social desirability.

Role-play, most commonly used by clinicians, allows direct observation of social skills when naturalistic observation is not possible. In role-play, children are asked to respond to a scenario or staged interaction. Although they can be used to elicit low-frequency behaviors that might not otherwise occur, role-play lacks generalizability because children may not respond to role-play as they would to real-world situations (Merrell, 2001).

Sociometric techniques assess peer relationships and interpersonal skills by asking children to rank classmates and identify peers they like/dislike and peers who exhibit specific behaviors, such as aggression. The reliability and validity of sociometric techniques are very strong, but there are many practical constraints. Sociometric techniques often require consent from all parents in a classroom, and parents are often reluctant to consent for fear that participation will reinforce social rejection (Merrell, 2001).

RISK AND PROTECTIVE FACTORS

Research documents that children who are disadvantaged or of minority status may be at risk for having difficulty socially and academically in early childhood. For example, studies have linked growing up in poverty to a number of risk factors, including poor achievement on cognitive and language outcomes, increased behavior problems (both externalizing and internalizing), increased stress levels, and

difficulties with self-regulation and emotion regulation (Dearing et al., 2006). Children from disadvantaged backgrounds also have been found to exhibit poorer learning-related skills and do worse on academic indices throughout elementary school compared to their peers (McClelland et al., 2006). These results suggest that income level and minority status can be risk factors in the development of social skills for children and adolescents.

One protective factor of children's social skills development is parenting. Parents who are warm and sensitive and set appropriate limits for children are more likely to have children with strong interpersonal and learning-related skills. For example, research has found that children's stress levels can be buffered by sensitive parenting, which can enhance children's social and emotional development (Gunnar, 2006). Finally, children of chronically depressed parents are more likely to have lower social skills in early childhood (NICHD Early Child Care Research Network, 2003), making it especially important to work with parents to effectively promote children's social skill development.

A number of studies have found that social skills deficits have been more often documented in boys than girls. Compared with girls, boys are more likely to be suspended and expelled at every grade level, drop out of school, exhibit behavior problems, and have lower education levels (Gilliam & Shahar, 2006). Research also indicates that girls have stronger aspects of learning-related skills and more adaptive classroom behavior than boys. One recent study found that girls had significantly stronger levels of self-regulation in kindergarten than boys, and there were greater numbers of boys scoring at the lowest levels on self-regulation over the school year compared to girls (Matthews, Ponitz, & Morrison, 2007).

Taken together, it is clear that a number of factors contribute to children's positive social skill development. Effective strategies for strengthening social skills involve a multi-faceted approach to working with children and parents.

EFFECTIVE CLASSROOM STRATEGIES

The teacher-child relationship plays a significant role in facilitating social skill development. Numerous studies have found that warm teacher-child relationships are associated with high levels of cooperation, social competence, and learning-related skills in early childhood and elementary school. Teacher-reported negativity, however, has been associated with social difficulties in children. The ratio of teachers to children in the classroom also relates to children's social skills. A smaller teacher-child ratio allows opportunities for children to work with teachers in small groups or one-on-one, and organization of children into smaller groups has been found to pro-

mote positive interpersonal and learning-related skills (Rimm-Kaufman, La Paro, Downer, & Pianta, 2005).

In addition to teacher factors, the classroom environment can facilitate the development of social skills. Classrooms that best promote these skills are child-centered and provide a stimulating, organized environment with ample opportunity for interaction (Cameron, Connor, & Morrison, 2005). Children demonstrate higher interpersonal and learning-related skills in classrooms where teachers provide organization and guidance, such as modeling appropriate social behaviors and problem-solving skills. Teachers can facilitate social problem-solving by demonstrating how to talk through the steps of a problem and by creating opportunities for children to practice social skills.

Children with social skills deficits most often have difficulties with one or more of the following areas: cooperation, communication, emotional understanding and regulation, aggression, and problem-solving (Bierman & Erath, 2006). To effectively help children who have social skills deficits, teachers can provide instruction and modeling of appropriate behaviors and responses. In young children, teachers can also create opportunities for children to practice and generalize social skills through classroom interactions. As children practice social skills, teachers should provide positive feedback to promote appropriate behaviors and redirect inappropriate behaviors.

Social skills (interpersonal skills and learning-related skills) are important for academic success and social well-being from early childhood through adolescence. Children without adequate social skills are at risk of peer rejection, behavior problems, and poor academic achievement. A combination of child, parent, and environmental factors influence the development of social skills and it is therefore essential for teachers and researchers to consider a child's context and use multi-faceted strategies to effectively promote positive social skills development.

SOCIOCULTURAL THEORIES OF MOTIVATION

For most educators, motivation is central to understanding and improving their students' classroom learning. While there is disagreement over its exact nature, most theories describe motivation as an *individual* phenomenon. Study of motivation has increasingly concerned the contexts in which motivated activity occurs. Of particular concern are specific *social* aspects of contexts (e.g. peers and classmates) and broader *cultural* aspects (e.g., societal values, cultural norms). Motivation theories that focus strongly on context are often described as *sociocultural* theories of motivation. This entry considers socioculturally oriented theories of motivation and, more broadly, the role of context in motivation theories. It contrasts sociocultural theories with more conventional theories, considers the distinctions between different sociocultural theories of motivation, and considers the practical implications of such theories of motivating classroom learning.

PRIOR THEORIES OF MOTIVATION

Most of the well-known individually oriented theories of motivation focus on either the behavior or the cognition of individuals. Following from the ideas of the behaviorist B.F. Skinner (1904–1990), theories that focus on behavior generally do not recognize motivation as something different from learning. Behavioral theories generally describe both motivation and learning in terms of how behavior is or is not reinforced by the environment. Because of this, behavioral theories describe contexts in terms of the patterns and relationships in the environment. Behavioral motivation theories argue that teachers

should structure classroom contexts so that learning can proceed in a very systematic fashion, and that students are appropriately rewarded for mastering very specific learning objectives.

The cognitive development theories of Jean Piaget (1896–1980) and the emergence of cognitive psychology in the 1970s led to very different theories of motivation. While still focusing on individuals, these theories made a clear distinction between learning and motivation. Well-known types of cognitive theories of motivation include social cognitive theories (e.g., *self-efficacy* and *self-regulation*) and intrinsic motivation theories (e.g., *self-determination*, *expectancy theory*, and *personal interest*). Historically, cognitive theories of motivation treated the sociocultural context as one of many factors that influence the motivation of individuals. Concern over the relevance of these theories by leading theorists such as Weiner (1990) led to increased concern with classroom and cultural contexts, particularly among motivation researchers who were concerned with education. This led to increased attention to the ways that classroom contexts, ethnicity, and culture influenced goals (e.g., Maehr & Pintrich, 1995), efficacy (Bandura, 2000), and interests (Hidi & Anderson, 1992). The implication of this trend for teachers was that their students' motivation was much more influenced by the classroom context and by the broader sociocultural context than had previously been assumed. In particular, this trend led away from explanations of motivation that focused on the individuals' genetic inheritance.

SOCIOCULTURAL THEORIES

Increased concern with sociocultural contexts in motivation and education more broadly reflects the influence of the Soviet theorist Lev Vygotsky (1896–1934). This influence began after Vygotsky's earlier works were translated into English (e.g., 1978). Vygotsky used the ideas of the philosopher Friedrich Engels (1820–1895) to understand how history and society impact the way that humans develop and learn. This led him to argue that knowledge originates in the social context. For some motivation theorists, Vygotsky's theories, when compared to theories that focused on individuals, provided a more useful explanation of the way that factors such as poverty and racism interfere with motivation for classroom learning. For example, Sivan (1986) proposed that the individual goals and values that motivate learning originate in the sociohistoric context, just as Vygotsky argued that language originated in the sociohistoric context. The practical implication of these theories is that explanations for differences in motivation should begin with the classroom, home, and sociocultural context, rather than the individual.

One well-known Vygotskian strand of motivational research involved studies of *adaptive learning* (e.g., McCaslin & Murdock, 1991) and *co-regulated learning* (McCaslin & Good, 1996). McCaslin and colleagues studied social and instructional environments found in the home and in the classroom. These studies provided detailed accounts of the way that students' regulation of their own thinking processes originated in the negotiation of goals and norms among students, teacher, and families. These studies were important because they identified the source of motivation as the relationships that students developed. This included relationships with school activities and relationships with the many other participants in school learning. Therefore, motivating classroom learners meant helping them coordinate the goals implied by a range of different relationships, and recognizing that some of the goals will conflict with other goals. This implies that before searching for strategies to motivate individual learners, teachers need to help students learn to negotiate worthwhile goals for themselves and their classmates. In doing so, teachers need to acknowledge the influence of other goals which might interfere with classroom learning, but which have real value for students.

McCaslin's studies helped pave the way for other studies that focused on the relationships that students had with other participants in the classroom and cultural contexts, including Järvelä and Salovaara (2004), Nolen (2007), Turner and Meyer (2000), and Yowell and Smylie (1999). By the start of the 21st century, "motivation in context" had emerged as an important theme among motivation researchers. This is particularly apparent in the treatment of motivation in educational psychology textbooks. While continuing to give ample treatment to motivational strategies that focus on individual learners, many also point out that teachers need to help the classroom community negotiate worthwhile goals, acknowledging that the students themselves help create and change these very goals.

SITUATIVE THEORIES

The most distinctively sociocultural theories of motivation are rooted in the "situative" theories of cognition that began taking shape in the 1990s. Like Vygotskian theories, situative theories assume that knowledge originates in social interaction and in cultural activity. However, situative theories assume that the knowledge primarily resides in these contexts as well. Situativity theorists argue that the abstract concepts that make up knowledge in cognitive theories and the specific associations that make up knowledge in the behavioral theories are "secondary" ways of describing knowledge. From this perspective, strictly behavioral or strictly cognitive

explanations of individual activity reflect the beliefs of particular researchers and the methods they use (Greeno & the MMAP, 1998). Situativity theorists believe that knowledge is “distributed” across tools, technologies, and social rituals that human cultures construct to let them work together. This means that knowledge and meaning are primarily rooted in the actual collective experiences people have in the world. According to Gee (2004), the abstract generalizations that are taken for granted in modern cognitive perspectives come at the end of a long process of socially situated activity if they come at all. Because of this, situative theorists believe that students’ learning is strongly attached to their participation in the construction of situated knowledge in socially meaningful activity.

Situative considerations of motivation for classroom learning first ask whether a particular learning context affords collective engagement in situated learning. In other words, are students and teachers negotiating a shared understanding of the concepts, terms, and rituals of the domain? This leads to a very different approach to motivation than prior approaches that focused on the activity of individuals. In one initial consideration, Hickey (1997) examined the motivational implications of situative instructional approaches that achieved prominence in the 1990s. This included the *cognitive apprenticeship* model defined by Collins, Brown, and Newman (1989). That paper suggested that the negative motivational consequences of competition might be more the result of lack of opportunity to engage in meaningful shared activity, rather than any fundamental consequence of competition.

Likewise, Hickey explored Bereiter and Scardamalia’s 1989 *intentional learning* perspective, which argued that learning environments first need to give students opportunities to participate in the construction of new knowledge in shared activity. They suggested that the widely held distinction between intrinsic and extrinsic motivation was too crude to be of much use in developing intentional learning environments. Both of these seminal considerations of situated learning suggested that the motivational strategies from earlier individually oriented theories of motivation might actually interfere with efforts to motivate engagement in situated learning. Given that situative theorists consider all learning to be socially situated, situative perspectives on learning seemed to have profound implications for motivating classroom learning.

One implication of this trend towards situated theories of motivation is that efforts to improve motivation for classroom learning should focus on *engagement*. This is because focusing on engagement requires being more specific about assumptions about learning. This issue was elaborated in Hickey and McCaslin (2001) who examined the implications of situative theories for motivating engage-

ment in learning. They argued that a situative focus on *learning to* participate in shared discourse (rather than *learning from* that participation) meant that teachers should focus their efforts at motivating that participation. Prior theories would focus on motivating students to encourage them to engage in discourse, and search for individual explanations when they failed to do so. Behaviorally oriented theorists would consider how the environment rewarded or punished individuals for participating in that activity. Cognitively oriented theorists would consider how the goals or values of the individuals affected the desirability of that activity.

In contrast, situative theories focus more directly on fostering worthwhile discourse among their students. This discourse occurs as students work together to make meaning of the terms, representations, and ideas that have already been negotiated by the community of experts in the particular academic domain. For example, the prevailing social norms in a math class should motivate students and teachers to encourage one another to use the mathematical term *vector* rather than the everyday term *point* during a lesson on geometry. Given the limits of human attention, this shift has major implications of teachers. This is because asking teachers to focus directly on such situated considerations of learning draws limited resources away from focusing on the behavior and/or cognition of each of their students.

Hickey and McCaslin (2001) also described the basic tension between earlier behavioral and cognitive views of motivation. As illustrated by the seemingly intractable debate over extrinsic incentives (e.g., prizes, competition, and grades), they argued that these tensions were a major obstacle to educational reform. Reflecting their very different views of learning, cognitive theorists have long argued that incentives interfere with natural learning processes, while behavioral theorists have long argued that incentive are useful for encouraging learning. Hickey and McCaslin argued that a relatively neutral situative view of motivation might offer a more useful lens for studying and comparing behavioral and cognitive strategies for motivating engagement. From a situative perspective, incentives and competition are not inherently good or bad. Rather, all motivational practices should first be analyzed in terms of their impact on students’ success at negotiating meaningfulness of the language and concepts of the particular academic domain. Importantly, a situative theory of motivation assumes that the success of these negotiations is the primary source of individual motivation towards the domain. Therefore it is the collective success of these negotiations that predicts whether or not those individuals will be motivated to engage in the practices of the domain in the future.

The notion of *engaged participation*, which was introduced by Greeno and colleagues (1998) provides a particularly appealing theoretical basis for a situated theory of

motivation. This theory focuses concern with motivation on participation in the rituals and practices of content domains that represent those domains in the activities of classrooms. This viewpoint argues that if the community of learners that makes up the classroom does not value participation in those rituals and practices, it is difficult for a particular individual to participate in them (Hickey, 2003). In contrast to sociocultural views that assume socially constructed goals and values are internalized by individuals, this viewpoint argues that goal and values remain alongside the knowledge practices in the sociocultural environment. While this distinction is philosophical rather than scientific, it has an important practical implication: as one's view of knowledge becomes more situated, the assumption that goals and values are internalized becomes less useful for motivating engagement (Hickey & Granade, 2005).

This raises fundamental questions about the scope of research that might inform teachers' efforts to motivate classroom learning. It argues that the wealth of existing sociocultural research on topics like identity (Holland, Lachicotte, Skinner, & Cain, 1998) and discourse (Gee & Green, 1998) are directly relevant for understanding motivated classroom learning. A particularly useful aspect of this research is that much of it concerns particular content areas, such as mathematics or science. When motivated classroom learning is viewed as engaged participation, this research becomes directly relevant for motivating that learning. Because this perspective assumes that specific motivational practices will have different consequences in different situations, teachers must be able to continually assess collective participation and adjust their practices accordingly. The current focus on individually oriented models of motivation in teacher education programs may be distracting from (or even undermining) the development of this ability.

One potential advantage of situative models of motivation is that they lend themselves well to the design-based research methods advanced by many situative educational theorists (e.g., Barab & Squire, 2004). These approaches build theory within efforts to reform educational practice. This is very different from the building of theory in highly controlled experiments or surveys (as in traditional studies of motivation) or naturalistic investigations of classroom or cultural activity (as in many of the recent study of motivation in context). Design-based methods are particularly relevant to educators because they highlight the value of theories that are developed in specific contexts for improving learning in those same contexts. Hickey and Schaffer (2006) proposed a model for improving classroom motivation over a series increasingly formal design-based studies. This first study would focus on highly situated analyses of motivation, using discourse analytic methods to increase collective partic-

ipation; this would be followed by more experimental studies of individual goals and values. A final cycle would use traditional program evaluation methods to look at the motivated behavior of all of the students. While elements of such an approach have been examined in initial studies (Hickey & Zuiker, 2005), the entire model has yet to be fully implemented or validated. The practical implications of such an approach is that if teachers focus their attention on directly enhancing their students' collective participation in domain-specific discourse, they will indirectly enhance the intrinsic motivation (e.g., goals and self-determination) of their individual students while improving the overall behavior (e.g., disciplinary actions and enrollments in advanced courses) over the student body.

Daniel Hickey

SOCIOCULTURAL THEORY

The work of *sociocultural theory* is to explain how individual mental functioning is related to cultural, institutional, and historical context; hence, the focus of the sociocultural perspective is on the roles that participation in social interactions and culturally organized activities play in influencing psychological development. While much of the framework for sociocultural theory was put forth by Lev Vygotsky (1931/1997), extensions, elabo-

rations, and refinements of sociocultural theory can be found in writings regarding *activity theory* (Chaiklin & Lave, 1993; Leontiev, 1981) and *cultural-historical activity theory* (Cole, 1996; Cole & Engestrom, 1994).

THE HISTORICAL ROOTS OF SOCIOCULTURAL THEORY

Lev S. Vygotsky, a psychologist in Russia who began his work following the Russian Revolution of 1917, is most closely identified with sociocultural theory. Vygotsky, argued: “The social dimension of consciousness is primary in time and in fact. The individual dimension of consciousness is derivative and secondary” (Vygotsky, 1979, p. 30, cited in Wertsch & Bivens, 1992). From this perspective, mental functioning of the individual is not simply derived from social interaction; rather, the specific structures and processes revealed by individuals can be traced to their interactions with others.

Wertsch (1991) proposed three major themes in Vygotsky's writings that elucidate the nature of this interdependence between individual and social processes in learning and development. The first is that individual development, including higher mental functioning, has its origins in social sources. This theme is best represented in Vygotsky's “genetic law of development”: “Any function of the child's cultural development appears on the stage twice, or on two planes, first the social, then the psychological, first between people as an intermental category, then within the child as an intramental category” (Vygotsky, 1931/1997, pp. 105–106).

From this perspective, as learners participate in a broad range of joint activities and internalize the effects of working together, they acquire new strategies and knowledge of the world and culture. Typically this tenet has been illustrated by examining the interactions between individuals with disparate knowledge levels; for example, children and their caregivers, or experts and novices. However, as Tudge and Scrimsher (2003) note, Vygotsky was not only interested in what more knowledgeable others brought to the interaction, but also in what the child himself or herself brought to the interaction, as well as how the broader cultural and historical setting shaped the interaction.

The second Vygotskian theme that Wertsch (1991) has identified is that human action, on both the social and individual planes, is mediated by tools and signs semiotics. These semiotic means include: “language; various systems of counting; mnemonic techniques; algebraic symbol systems; works of art; writing; schemes, diagrams, maps and mechanical drawings; all sorts of conventional signs and so on” (Vygotsky, 1981, p. 137). Additional semiotic means include: computers, calculators, paint brushes and the like, all of which are

useful in representational activity. These semiotic means are both the tools that facilitate the co-construction of knowledge and the means that are internalized to aid future independent problem solving activity.

Leontiev (1981), a colleague of Vygotsky, used the term “appropriation” to characterize this process of internalization:

[Children] cannot and need not reinvent artifacts that have taken millennia to evolve in order to appropriate such objects into their own system of activity. The child has only to come to an understanding that it is adequate for using the culturally elaborated object in the novel life circumstances he encounters. (Quoted in Newman, Griffin, & Cole, 1989, p. 63)

The third theme that Wertsch (1991) proposes from Vygotsky’s writing is that the first two themes are best examined through genetic, or developmental, analysis:

To study something historically means to study it in the process of change; that is the dialectical method’s basic demand. To encompass in research the process of a given thing’s development in all its phases and changes from birth to death fundamentally means to discover its nature, its essence, for it is only in movement that a body shows what it is. Thus the historical study of behavior is not an auxiliary aspect of theoretical study, but rather forms its very base. (Vygotsky, 1978, pp. 64–65)

In contrast to prevailing views of his time, in which learning was regarded as an external process and development an internal process, Vygotsky was concerned with the unity and interdependence of learning and development. For example, he was critical of Piaget’s theory in which “maturation is viewed as a precondition of learning but never the result of it” (Vygotsky, 1978, p. 80). In contrast, Vygotsky proposed:

Learning awakens a variety of internal developmental processes that are able to operate only when the child is interacting with people in his environment and with his peers. . . . learning is not development; however, properly organized learning results in mental development and sets in motion a variety of developmental processes that would be impossible apart from learning. Thus learning is a necessary and universal aspect of the process of developing culturally organized, specifically human, psychological functions. (p. 90)

In support of this perspective, Vygotsky (1978) introduced the construct of the *zone of proximal development* (ZPD) as a fundamentally new approach to the problem that learning should be matched in some man-

ner with the child’s level of development. He argued that to understand the relationship between development and learning, two developmental levels must be distinguished: the actual and the potential levels of development. The actual refers to those accomplishments a child can demonstrate alone or perform independently; in contrast to potential levels of development as suggested by the ZPD what children can do with assistance: “The distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers” (p. 85). The ZPD was regarded as a better, more dynamic and relative indicator of cognitive development than what children accomplished alone. In summary, productive interactions are those which orient instruction toward the ZPD; otherwise, instruction lags behind the development of the child. “The only good learning is that which is in advance of development.” (Vygotsky, 1978, p. 89). Hence, from a Vygotskian perspective, cognitive development is studied by examining the processes that one participates in when engaged in shared endeavors and how this engagement influences engagement in other activities. Development occurs as children learn general concepts and principles that can be applied to new tasks and problems; whereas from a Piagetian perspective, learning is constrained by development.

Vygotsky was a prolific writer; he advanced a vast number of ideas in his brief life as a scholar (he died when he was but 37), some of which are appropriately characterized as underspecified and emergent. One of the most frequently criticized facets of Vygotsky’s theory is its model of internalization. For example, Cobb and Yackel (1996) have argued that this aspect of Vygotskian theory constitutes a transmission model in which “students inherit the cultural meanings that constitute their intellectual bequest from prior generations” (p. 186). There is an alternative model, the *participation model of cultural development* (Lave and Wenger, 1991; Rogoff, 1990), which seems useful to overcoming dualisms, such as the society and the individual. The participation model represents development as the transformation of individual participation in sociocultural activity. Transformation (rather than internalization) occurs as participants in the activity assume increasing responsibility for the activity; in essence, redefining membership in a community of practice, and, in fact, changing the sociocultural practice itself. These ideas are elaborated on below.

THE CONCEPT OF GUIDED PARTICIPATION

The concept of guided participation highlights that cognitive development occurs in a social context while extending sociocultural theory beyond language-based dialogue. Importantly, guided participation builds on and extends Vygotsky's notion of ZPD. Rogoff (1990) writes, "Children's cognitive development is an apprenticeship—it occurs through guided participation in social activity with companions who support and stretch children's understanding of and skill in using the tools of the culture" (p. vii). While this sounds very similar to ZPD, Rogoff explicitly states that guided participation focuses more centrally on the interrelatedness of children and caregiver interactions and the fact that the "guided" does not necessarily mean face to face. For example, a student working on a research report in isolation is still "guided" by the teacher, librarians, classmates, the publishing industry, and parents who help shape the writing of the research report as a cultural activity. Emphasis on tacit, distal, and non-verbal forms of communication stands in contrast to Vygotsky's emphasis on didactic dialogue. This helps broaden the lens of sociocultural theory beyond language-based interactions as the primary source of learning culture. Finally, socioculturally oriented research, generally, and research on guided participation, specifically, have played important roles in bridging research on in-school and out-of-school learning.

HOW SOCIOCULTURAL THEORY DIFFERS FROM CONSTRUCTIVIST THEORY

Similar to sociocultural theory, constructivism emerged as a theory of knowledge in response to behaviorism. Immanuel Kant (1724–1804) and Jean Piaget (1896–1980) are two theorists whose thinking and research significantly shaped constructivist theory. Kant (1951) significantly influenced Piaget's thinking when he proposed that it is the mind that provides the categories of knowing, while experience yields the content. Piaget (1955) argued that it is through the child's experiences manipulating and changing the world that the child acquires knowledge about relations within and between people and objects.

Both constructivism and sociocultural theory, when applied to learning, are concerned with the activities that children engage in to learn. However, constructivist theory suggests one should attend to the learning and mental representations of the individual while sociocultural theory is more concerned with the ways in which learning is an act of enculturation. Many learning situations attempt to accommodate both, for example, the mathematics teach-

ing of Ball (1993). Cobb (1994), in looking at Ball's dilemma of attending to students' individual knowledge (math as an active construction) and the traditions that have grown out of centuries of mathematics as a discipline (math learning as enculturation), notes that the dual presence of both sociocultural and constructivist theory can act as competing aims for teachers.

The lens of sociocultural theory is considerably wide when compared to constructivist theory. A sociocultural theorist, when interpreting a learning situation, might attend to the broader social system in which the learning is happening and will draw interpretations about an individual's thinking and development based on his or her participation in culturally organized activities. An account of learning and development through the lens of constructivist theory, in contrast, is concerned with the individual and the ways in which sense making happens through the individual's accommodation of experience (Cobb, 1994).

Giyoo Hatano was most skillful at bridging sociocultural perspectives on learning with constructivist theories of learning that resulted in a "mixed" theory of conceptual knowledge that successfully accommodated both perspectives (Cole & Miyake, 2006). In an attempt to understand whether cognitive development proceeded along a predetermined innate set of principles, Hatano and Inagaki (1994) explored the long-held theory, first put forth by Piaget (1929) that children come to develop theories of biology rather late in the course of development. Through experimental work with Japanese schoolchildren, they demonstrated that theories of cognitive development must also account for the role that experience plays in advancing development, thus accommodating Vygotskian ideas about the social nature of learning.

THE EDUCATIONAL IMPLICATIONS OF SOCIOCULTURAL THEORY

Given the comprehensive nature of sociocultural theory, its educational implications for assessment, curriculum, and instruction are broad-ranging, and only a glimpse of them can be provided in this entry. For example, sociocultural theory—in particular the notion of zones of proximal development—would suggest that the goals of educational assessment should be to: (a) identify abilities that are in the process of developing, and (b) attempt to predict what the learner will do independently in the future. A line of inquiry consistent with these assessment goals is *dynamic assessment*. Dynamic assessment is a term used to characterize a number of distinct approaches that feature guided learning for the purpose of determining a learner's potential for change. In contrast to traditional and static procedures that focus on the products of assessment, dynamic assessment is concerned with the different ways in which individuals who earned the same score

achieved that score. Furthermore, while traditional measures reveal only those abilities that are completely developed, dynamic measures are concerned with how well a learner performs when provided assistance. Initial inquiry into the design and use of dynamic assessment used domain-general types of problem-solving tasks (e.g., Campione & Brown, 1984; Feuerstein, 1980). These studies suggested that dynamic assessment measures did indeed reveal a different picture of competence than do static measures, which typically underestimate children's ability to learn in a domain in which they initially performed poorly.

More recent research suggests that the principles of dynamic assessment can also be applied within academic contexts. For example, Magnusson, Templin, and Boyle (1997) conducted research on the use of dynamic assessment to determine students' conceptions regarding the flow of electricity. They devised a context in which students could test out their conceptions and revise their thinking based upon the outcomes of their investigations. In this context, the researchers determined that students were, indeed, able to understand more about electrical behavior than had been determined on static measures used in previous research.

Instructional Implications. Informed by a sociocultural perspective, learning is thought to occur through interaction, negotiation, and collaboration. While these features are characteristic of "cooperative learning," what sets instruction that is informed by sociocultural theory apart is that there is also attention to the discourse, norms, and practices associated with particular discourse and practice communities. The goal of instruction is to support students to engage in the activities, talk, and use of tools in a manner that is consistent with the practices of the community to which students are being introduced (e.g., scientists, mathematicians, historians).

These tenets are consistent with inquiry-based approaches, in which teachers and students are co-inquirers, but with teachers mediating among students' personal meanings, the meanings emerging from the collective thinking and talk of the students, and the culturally established (scientific, mathematical, historical, literary) meanings of the wider society. Examples of research of this kind can be found in mathematics (Ball, 1993; Cobb, Wood, & Yackel, 1993; science (Engle & Conant, 2002; Magnusson & Palincsar, 2005; Wells & Chang-Wells, 1992), history (Bain, 2006), and literary studies (Smagorinsky & O'Donnell-Allen, 2000; Lee, 2007).

Sociocultural theory has also been called upon to advance instructional practice that might redress disparities in the current educational system. Forty-two percent of school-aged children in the United States struggle to advance beyond basic levels of reading comprehension.

Minority students and children living in poverty disproportionately perform in the lowest quartile on standardized measures of reading ability (Perie, Grigg, & Donahue, 2005). Given these distressing statistics, the increasing diversity in U.S. classrooms, and the proliferation of literacy technologies (e.g., multimedia and information and communications technologies), teachers have been challenged to reconsider the canonical approach to literacy instruction (e.g., Lee, 2007). A view of literacy instruction through the lens of sociocultural theory helps educators understand the situational specificity of literacy practice. From this perspective, educators would consider literacy as a tool for use in specific contexts; thus, children would be taught how to negotiate multiple literacies for use in multiple contexts.

Some researchers (Bhaba, 1994; Gutiérrez, Baquedano-Lopez, & Tejada, 1999; Moje et al., 2004; Soja, 1996) have advanced the idea that educators work to develop a *third space* in which students' primary discourses (those used in the home, community, and informal social interactions) and students' secondary discourses (those endorsed in school and other formal institutions) intersect to form this third space, where primary and secondary discourses are merged. Were educators to be more attentive to the creation of these third spaces in school, greater attention would be paid to incorporating students' prior knowledge and experience, as well as current literacy practices in the school curriculum. Research conducted by Varellas and Pappas (2006) illustrates the productive instructional use of discourse in third spaces to promote science learning. Working in primary-grade classrooms in an urban school, teachers encouraged their students to draw upon: (a) their own explorations of scientific phenomena (such as the water cycle) in classroom, home, and community settings; (b) prior conversations, and (c) other books read in and out of school in the course of read-aloud sessions. Varellas and Pappas documented numerous examples of young children bringing their own funds of knowledge to the classroom setting, but they also documented how the teachers made facile use of these funds and promoted the children's learning of scientific language and concepts.

Use of New Technologies. With the proliferation of information and communication technologies in educational and everyday settings, scholars, working from a sociocultural perspective, are working to expand concepts, such as distributed cognition, to include not only people and artifacts, but also digital technologies. For example, Shaffer and Clinton (2006) introduce a new category of tool, which they call, *toolforthoughts* and, in doing so, challenge the idea that humans occupy a privileged position in psychological analyses. They argue that media, such as video games, word processors, and analytical tools

create new skills and habits of mind, in addition to shifting the focus from reading and writing the printed word to multimodal literacy.

Recently, sociocultural theory has been taken into consideration in the design of online distance education technologies. Research on the social context of learning has provided ample evidence that traditional teacher-centered approaches would be inappropriate in an online setting. It is less clear, however, how to design online learning environments in which students feel connected to peers and professors in a virtual classroom community. Community building in asynchronous learning networks poses a particular challenge from the perspective of sociocultural theory because students are often not together physically or even virtually. Brigham Young University (BYU), a large provider of accredited online distance education in the United States, has adopted a model of online distance learning that is designed with sociocultural theory in mind. ProfessorsPlus™ carefully integrates social interaction among participants, substantive and interactive assistance from the course facilitators, and dynamic course content that is responsive to student learning (Teemant, 2005).

Research Applied to Institutional Settings. Research conducted from a sociocultural perspective has focused traditionally on the interactions of individuals and groups of individuals. However, research has also applied this lens to much larger institutional settings. For example, Cobb and McClain (2006) illustrate how efforts toward a mathematics reform effort need to be analyzed at a teacher, classroom, school, district, and indeed state and federal policy levels, to provide a more complete accounting of the reform effort.

Broad-scale use of assessments represent another approach to educational reform, and similarly, must also attend to the larger institutional settings in which the assessment instrument is positioned. Moss and her colleagues (Moss, Girard, & Haniford, 2006), in their work on validity theory, describe educational measurement as a cultural tool situated within a larger institutional, social, and national context. Applying the lens of sociocultural theory, they urge that interpretations of student performance on these tests must be made with attention to the local context, the purposes for which the test was written, and the larger policy context in which the test is situated.

SOCIOECONOMIC STATUS

Socioeconomic status (SES) is the measure of the influence that the social environment has on individuals, families, communities, and schools. In many ways SES is related to the concept of social class. Both have financial stability as a foundation for classification. Both are important to a child's optimal development and an adult's satisfaction with life. However, the concept of social class is considered to be continuous throughout one's lifetime and from one generation to the next. The SES classifications are established in an effort to find the means of identifying and changing inequalities. In addition, social class has economic differences as a primary influence. The concept of SES considers other influences such as the chance for social or economic advancement, influence on policy, availability of resources, and prestige of the primary occupation.

DEFINITION

The definitions of SES emphasize that, as a construct, (1) it is conditional, (2) it is imposed on people, (3) it is used for comparisons, (4) it is based on economics, opportunity, and means of influence. Santrock (2004) defines it as “the grouping of people with similar occupational, educational, and economic characteristics” (p. 583). Woolfolk (2007) calls SES “the relative standing in society based on income, power, background and prestige” (p. 165). Santrock (2004) adds that an important qualification is “the ability to control resources and participate in society's rewards” (p. 583). Woolfolk (2007) also notes that every researcher will define it differently based on the nature of the study. In most discussions, there are three levels of SES: low, moderate, and high. Because most problems associated with low SES are related to poverty, sometimes poverty level is used as a similar concept to low SES. Race may also be considered a factor because Blacks and Latinos are disproportionately represented in the low SES.

MEASUREMENT OF SES AND VARIOUS COMPONENTS

The factors that are usually considered in establishing SES are income, occupation, education, neighborhood, and political power. For each of these five factors, the consideration of how fixed each one is also contributes to SES. For example, if a family is considered low income because one of the parents is in school to eventually get a better job, then the family is not really in the same SES as their neighbors who have little hope of a better job.

Individuals' SES is usually determined by the SES of their family. The SES of the family is calculated based on the measure of the five factors noted above. How well can the family members meet their financial responsibilities?

What prestige is associated with the occupation of the head of the household? What level of education have the parents achieved? What is the safety and upkeep of the neighborhood in which the family lives? What hope do the family members reasonably have to influence the government and community policies that affect their lives? A school's SES is determined by the neighborhood in which it is located and by the SES of the families whose children attend the school.

SCHOOL OUTCOMES AND PERSONAL SES

The negative effects of low SES can interfere with a child's cognitive development. Among families of low SES, there are more occurrences of lead poisoning, fetal alcohol syndrome, and premature birth. Lead poisoning, caused by the child ingesting bits of the lead paint found in old buildings, produces neurological disorders. Children born to women who drink alcohol during pregnancy develop fetal alcohol syndrome, a condition that includes mental retardation. The child from a premature birth experiences a diminished brain development. All of these problems lead to language delays, attention problems, and learning disabilities.

Observed family differences based on SES include those constituting parenting styles. Comparing high SES parents to low SES parents, the high SES parents tend to be less directive and more conversational in their communication with their children. Low SES parents are more likely than the high SES parents to expect obedience without question from their children. Low SES parents encourage their children to conform to society's expectations, while the high SES parents encourage creativity and exploration. These differences foster self-confidence in the high SES students and an uncertainty about life in the low SES students.

Young people in the low SES neighborhood report as many pleasant experiences as the young people in high SES neighborhoods. However, children growing up in a low SES neighborhood are more likely to experience distressing events than their counterparts in the higher SES neighborhoods. These include physical punishment in the home, domestic violence in their home building, and serious crime in the neighborhood. Such demoralizing experiences lead to higher rates of depression, low self-esteem, and juvenile delinquency among children from the low SES neighborhoods.

Some children are resilient and able to develop normally under difficult conditions. However, for most children long-term problems are associated with the amount of time living in poverty.

RELATIONS BETWEEN SCHOOL OUTCOMES AND SCHOOL SES

Schools in low SES neighborhoods tend to have fewer resources. Their students, beginning school with little preparation, require an educational system with a more skillful and focused approach. However, the teachers in the low SES schools are often less paid and less trained than the teachers in the higher SES schools. The results are low achievement rates for the students. Few high school students in the low SES schools plan to attend college; therefore, the graduation rate is low.

One of the big problems in school for children of low SES is the self-fulfilling prophecy of failure. If the children do not dress well or are too shy, the teacher may not feel they are very bright. The teacher will call on these students less often and not regularly engage them in class discussion. These students are then left feeling as if they do not belong in school and as if they do not have hope of doing well. If learned helplessness builds in the students' self-concept, they will look for experiences that confirm this self-concept. This process is especially strong if the students are from an ethnic minority and face discrimination.

In mixed SES schools, the practice of tracking can negatively affect the low SES student. Tracking involves assigning students to classes in one grade based on their achievement level in the previous year. There are different expectations for the hierarchy of tracks; the high tracks set higher academic priorities and offer more encouragement than the lower tracks. Tracking disproportionately assigns low-SES students to low-achieving classrooms. Thus, the students who need the most stimulation and motivation are given the least. The original disparity between the achievement levels of the high-track students and the low-track students widens as tracking continues.

The schools in low SES neighborhoods suffer from the lack of support from the students' homes. The home environment contributes substantially to the development of academic skills. Enriching experiences in the home can contribute up to one-half of the measured achievement in verbal skills, reading, and mathematics. Three main factors distinguish the home environment of the high SES student from that of the low SES student. The high SES student is likely to do more reading, more skill building, and less television watching in the home than the low SES student, even during summer vacation (Woolfolk, 2007).

These factors are most closely associated with the educational level of the mother. The mother in the high SES family can be expected to have graduated from college. The college-graduate mother recognizes the need for home enrichment; the low-education mother likely does not. However, these problems can be resolved if the

low SES schools help the parents recognize ways to improve the home learning environment, such as turning off the television. As a passive activity, watching television discourages critical thinking. Parents have to recognize that television is an educational medium that does not always present accurate information.

There are examples of low-SES students keeping up with (or even surpassing) the higher SES students. There are two serious conditions that have to be considered regarding these cases. Often, the achievement is only seen during the school year. During the summer the low SES student is likely to fall behind. The other condition occurs when the achievement level is continuous. There is usually one or both parents making the necessary sacrifices to ensure that the home life provides enrichment for (and prevents interference with) the child's academic achievement.

The detrimental effects of low SES on early childhood can be ameliorated by quality preschool programs. One such program, Head Start, has existed since the 1960s. Its goal is to give children of low SES families a chance to be better prepared for school. Similar programs include the High/Scope Preschool in Michigan, Abecedarian Intervention program in North Carolina, and Child-Parent Center in Illinois. These programs have been shown to have longitudinal effects on the cognitive development of the children attending. The results are higher reading and math scores than other children of low SES families. Furthermore, the programs' attendees are more likely to finish high school and less likely to commit a crime than their peers.

SOCIOMETRIC ASSESSMENT

Sociometric assessment can be defined as the measurement of interpersonal relationships in a social group. Sociometric measurement or assessment methods provide information about an individual's social competence and standing within a peer group. School-based sociometric assessment often focuses on a child's relationships with regard to social popularity, peer acceptance, peer rejection, and reputation. Some sociometric assessment methods derive

information on social relationships by assessing children's positive and negative social perceptions of one another, whereas other methods involve adult (teacher, parent) and self perceptions of children's social competencies or standing. Sociometric assessment methods were introduced in the 1930s and advanced in the journal *Sociometry*. In the 1950s, several books were published on the topic and sociometric measurements often were part of research and school-based assessments of social relationships. The use of classic sociometric procedures declined in the following decades, due to the advancement of social behavior rating scales and ethical concerns regarding the use of peer nomination methods with children.

SOCIOMETRIC ASSESSMENT METHODS

There are a variety of what can be referred to as classic sociometric assessment techniques derived from the work of the 1930s, including peer nomination, peer rankings, and sociometric rankings. In the peer nomination technique, children in a social group or school classroom anonymously identify social preferences for their classmates. For example, children may be asked to provide a list of the three classmates with whom they would most like to play and the three with whom they would least like to play. Another peer nomination technique (see Figure 1) is to provide a list of the names of the children in a classroom along with social acceptance items (e.g., "Who do you like to play with?" "Who is most likely to be alone during recess?" "Who gets into trouble the most?"). The children are asked to identify perhaps one to three classmates who they perceive best fit the item description.

An alternative peer nomination method for early readers is to use photographs with an adult reading the items aloud in either an individual or classroom setting while the children provide a nomination for a child, perhaps by assigning a smiling or frowning face to the photograph that applies. Another variation of the peer nomination method is the class play. In this procedure children cast their peers in positive and negative roles in an imaginary play. The class play has the potential advantage of being more acceptable in school settings because the positive and negative role assignments may be perceived as a more discreet method for identifying children's social standing. For each of the methods described, the nominations may be summed for each child and the results are used to identify those children who are perceived as most socially positive or negative by their peers.

Two other sociometric techniques can be described as peer ratings and sociometric rankings. Peer ratings are conducted by providing a list of children's names in the social group or classroom along with a rating for social acceptance items such as "The most fun to play with,"

Example of a peer nomination technique									
Place an X under the name of one classmate in answer to each question below	Alma	Bart	Carl	Dave	Edna	Fayd	Gigi	Holz	Inez
Who would you most like to play with?		X							
Who would you least like to play with?							X		
Who gets into trouble the most?				X					
Who is most likely to be alone during recess?		X							
Who gets along best with others?	X								

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

“The least fun to play with,” and “Has the most friends.” The rating methods that are used may vary, typically ranging from three- to five-point Likert-type responses (e.g., Agree, Neutral, Disagree). In contrast to peer nominations and ratings, sociometric rankings are completed by an adult, most often the classroom teacher who has had the opportunity to observe the children in multiple social settings such as the classroom, playground, and cafeteria. In this method, teachers rank the children on social dimensions similar to those provided by peers.

Each of these sociometric assessment methods has strengths and limitations. Researchers have found that each method appears to be valid for identifying children’s social standing. Peer ratings and adult rankings appear to provide the most reliable or stable measurements and, as such, may be more useful than the peer nomination method. A major issue that arises with each of these methods is the concept of social validity, which refers to the acceptance, usefulness, and potential harm of an assessment procedure. The applications of sociometric assessment methods have resulted in controversy and ethical concerns regarding their use. These concerns center on the use of negative peer nominations and the possibility that children will compare responses which may result in negative social and emotional consequences for children who are not positively perceived by their peers. These concerns contributed to the decline in the acceptance and use of sociometric assessment methods, particularly in school settings. However, researchers have found no strong evidence that negative consequences occur for either the children who are rating or those being rated; therefore, sociometric assessment continues to be used as a research tool for understanding children’s social relationships.

RELATED ASSESSMENT METHODS

Although the term sociometrics has been most often applied to the assessment methods described above, in a broader context the term can be applied to related assessment measures of social functioning. These methods tend

to focus on children’s social competencies and skills rather than measuring only social standing or peer acceptance. Because these methods are more often used in practical applications in school settings, they are briefly described here.

Social Behavior Rating Scales. Social behavior rating scales represent one of the most frequently used measures of social competence. These rating scales are designed for gathering data on the frequency of occurrence of specific skills or behaviors. Some rating scales focus on social problem behaviors and others are designed specifically to assess children’s social skills. For example, a social skills rating scale may contain items such as “Appropriately invites friends to play” or “Controls temper in conflicts with adults” which are rated on a frequency scale (e.g., Never, Sometimes, Always). Depending on the measure, ratings can be gathered from parents or parent surrogates, teachers, and when appropriate from the children themselves. Rating scales in essence provide summary observations of a child’s social behavior. Gathering data from these multiple sources can facilitate understanding different perspectives regarding a child’s social skills in home and school settings. Well designed social skills rating scales have been found to be reliable and valid measures.

Observation Methods. Observation methods are used to gather information about a child’s social skills in natural settings, such as in the classroom, in the cafeteria, and on the playground. Observation methods can be highly structured wherein defined behaviors are measured for frequency of occurrence or measured for occurrence during specified time periods or intervals. For example, a child’s play behavior may be observed during recess by a school psychologist who records every 30 seconds whether the child was playing alone or with others. Other observation methods are less structured and rely on a narrative approach for describing a child’s social interactions. Observation methods often include focus on the

environmental variables that may increase or decrease a child's social skills, such as the reactions of peers and adults to a child's attempts at initiating conversation. Observations also can be conducted in what is known as analogue assessment, which involves having a child role-play social scenarios and observing the child's performance. Whereas rating scales provide summary measures that rely on some level of recall, observations have the advantage of directly sampling a child's behavior in actual social contexts or settings, thereby increasing the validity of the assessment. The limitations of observations are that multiple observers are required to ensure reliable assessment (interobserver agreement) and observations are more time intensive. Thus in applied settings they may provide limited information due to time constraints.

Interview Methods. Interview methods are used to gather information about a child's social skill strengths and weaknesses, and to aid in the identification of specific skill deficits for intervention. Interviews can be used separately with children, parents or parent surrogates, and teachers, or conjointly with multiple sources. Interviews can be structured, with a focus on the identification and treatment of specific social skills, or interviews can be less structured, with a greater focus on feelings and perceptions about a child's social skills. As with rating scales, interview data can be viewed as summary recall information which should be validated with direct observation.

The assessment methods described often are combined in a comprehensive social skills assessment that may include rating scales, observations, and interviews. Using multiple methods of assessment is considered best practice because the use of more than one assessment method increases the likelihood that the behaviors which are targeted for classification or intervention are valid, and that specific social skills strengths and deficits are clearly defined. It is also important to use multiple assessment methods to monitor a child's progress and to assess the effectiveness of an intervention.

IMPLICATIONS OF SOCIOMETRIC ASSESSMENT FOR EDUCATIONAL PRACTICE

In educational practice, sociometric assessment most often is used to determine eligibility for special education and for intervention for adaptive behaviors or socio-emotional problems. Children identified with special education needs, such as learning problems, mental retardation, attention deficit disorders, and autism spectrum disorders, including Asperger's syndrome, may benefit from assessment and intervention toward enhancing their social skills. In the general education population, children may benefit who are shy, rejected, or engage in bullying or aggressive

behaviors or who simply have limited social skills. Most of the classic sociometric assessment methods are not used in educational practice, partly due to issues with acceptability. Furthermore, although these methods have been found to be useful in research, they may not be viewed as being useful in school settings because they do not lead to specific classification for special education nor do they provide specific data that can directly assist in the intervention process. Related sociometric assessment measures such as rating scales often are used because these methods provide more specific information that can be linked to classification and intervention.

One classic sociometric assessment method that has been shown to be effective in educational practice is sociometric rankings. In this procedure teachers rank the children in their classroom who the teacher views as having social behavior problems, sometimes in relation to internalizing and externalizing problem behaviors. (Internalizing behaviors refer to problems such as depression, anxiety, and social withdrawal; externalizing behaviors refer to problems such as aggression, conduct problems, and hyperactivity.) The use of teacher rankings serves as an initial screening device for identifying children who may need additional assessment and intervention. Once identified, the children are screened further with a rating scale or related method to determine the extent of their social difficulties. Those children who are found to have problems are then referred for more assessment intended to specify their problems and provide an intervention, such as social skills training. Researchers have found this method of assessment, known as a multiple gating procedure, to be acceptable and effective in applied settings.

Assessing and understanding children's and adolescents' peer relations is important in educational settings for several reasons. From a developmental standpoint, it is important to understand how children develop social skills as they mature. Researchers have found that sociometric assessment can be useful in identifying children's social standing and predicting positive or negative social outcomes for children. The establishment of friendships and positive social interactions are important for children's social development and for interacting in the social world, including the school setting. Children with poor peer and adult relationships often experience negative social and emotional consequences that can continue throughout adulthood. These negative consequences can include lower academic achievement, higher rates of school dropout, depression, anxiety, low self-esteem, poor self-concept, social withdrawal, fewer positive employment opportunities, and anti-social behaviors such as aggression and criminality. Researchers have estimated that at least 10%, or one in ten children experience consistent negative peer relationships. Therefore, a large number of children with inadequate social relationships may be at-risk for developing

behavioral and emotional difficulties. Children with poor or limited social skills also are at risk for becoming victims of bullying and other aggressive behaviors. Children with disabilities often have social skills deficits and negative peer perceptions that put them at heightened risk.

Given these potentially negative outcomes, social skills assessment is important in educational settings. In research, the identification of the development of social standing and social skills can facilitate understanding the behaviors of socially successful and unsuccessful children. In research settings, both classic sociometric assessment and social skills assessment methods are used to achieve better understanding of social types and behaviors. These behaviors can in turn be used to understand children's and adolescents' social skill deficits and can aid in the design and study of social skills assessments and interventions.

SPEARMAN, CHARLES EDWARD 1863-1945

Charles Edward Spearman was born in London on September 10, 1863, into a respected family. As a student, he demonstrated a superb mastery of mathematics and

Charles Spearman ARCHIVES OF THE HISTORY OF AMERICAN PSYCHOLOGY. THE UNIVERSITY OF AKRON.

science but held a "secret devotion to philosophy" that would last his entire life (1930, p. 299). Following graduation from college, Spearman secured a commission as an officer in the Royal Engineers of the British Army. Spearman was assigned to a post in Burma, where he served honorably and rose to the rank of major. During this time, his continued interests in philosophy led to the belief that many of the debated issues of philosophy could be resolved successfully by applying the empiricism of psychology. So at the age of 34, Spearman abandoned a successful military career and began study in the Leipzig laboratory of Wilhelm Wundt. Despite his obvious military success, Spearman later portrayed his 14 years of service as "the greatest mistake of my life, [based on] the youthful delusion that life is long." (1930, p. 300).

Although Wundt is considered a founding father of psychology, Spearman's greatest influence came from Sir Frances Galton (1822-1911). After reading Galton's *Hereditary Genius* (1869) and *Inquiries into Human Faculty and Its Development* (1883), Spearman seized on two principles that guided the remainder of his life's work. First, individual differences in sensory, motor, and cognitive abilities may be measured precisely using

standardized techniques. Second, there exists a biologically based general mental ability that enters into every kind of mental activity.

At his own personal expense and without the support of Wundt, Spearman conducted a study to test the Galtonian notion that individual differences in sensory discrimination and modality were positively correlated with varied measures of cognitive ability. As the logic goes, positive correlations among the variables would demonstrate the existence of a common source of variation (i.e., the presence of a general ability). To accomplish his aim, Spearman invented the statistical technique of factor analysis to analyze the matrix of correlations among variables. Spearman published this study as a 1904 article titled "General Intelligence, Objectively Determined and Measured." The article garnered considerable scientific interest, both for its surprising support of Galton's theory of general ability, as well as its innovative statistical methodology. Following further military service in the Boer War, Spearman finally completed his doctoral study in experimental psychology in 1906. By that time he was 42 years of age but with "more distinguished scientific accomplishments to his credit than probably any other new Ph.D. in the history of psychology" (Jensen, 2000, p. 4).

Spearman joined the Department of Experimental Psychology at University College, London, where he was promoted to full professor in 1911. He continued his research into general ability and expanded investigations to include group differences, psychometrics, eugenics, and learning. Spearman retired in 1931, but continued to play an active role in field of educational psychology. After retirement, Spearman taught in North America at Columbia University, where his students included David Wechsler and Raymond B. Cattell.

During his esteemed career, Spearman received numerous honors, including Fellow of the Royal Society and membership in the United States National Academy of Science. In 1945, with failing health at age 82, Spearman reportedly committed suicide by jumping from a window of the London University Hospital, where he was a patient.

Spearman is credited with offering the first truly tenable psychometric definition of intelligence and is, therefore, considered to be the founding father of classical test theory. This approach, which considers an individual's observed score as consisting of a *true score* plus *error score* has been particularly influential in test development and conceptions of reliability. Spearman's best known contribution to statistics is the rank-order correlation coefficient, a nonparametric index of association between two ordinal variables. Additionally, Spearman's development of factor analysis is the first direct application of latent trait theory, which advances that individual

differences in observed test scores serve as reflections of some smaller number of hypothetical, or latent, variables. This technique is routinely used to determine the construct validity of tests. Undoubtedly, Spearman's most important discovery was the identification of a general factor of mental ability (i.e., Spearman's *g* or *g factor*). A century of research finds that Spearman's *g* is the largest singular source of individual differences in mental ability and learning, regularly accounting for approximately half of the variance in test scores (Jensen, 1998).

Since its explication in Spearman's seminal 1904 article, the *g factor* has garnered considerable support and controversy. The continued interest and influence of Spearman's research can be traced to a number of developments, including the spread of universal public education, an increased range in the intelligence and scholastic achievement of the school population, and the rising cognitive demands of a complex modern society and workplace. In the early 2000s, one of the liveliest and most productive lines of research in cognitive neuroscience and biogenetics is the search for the physiological/genetic provenance of Spearman's *g* (Brand, 1996; Meisenberg, 2005). As testimony to his originality and continued influence, Spearman is one of the few psychologists showing an increasing rate of citations since his death.

SPECIAL EDUCATION

As defined by U. S. law, special education is: “specially designed instruction, at no cost to parents, to meet the unique needs of a child with a disability, including instruction conducted in the classroom, in the home, in hospitals and institutions, and other settings; and instruction in physical education” (Individuals with Disabilities Education Improvement Act, 2004) 20 U.S.C. § 1401 (29). The law also stipulates that students with disabilities are entitled to related services, as needed. Related services include such services as transportation, occupational and physical therapy, and psychological, counseling, speech/language pathology, audiology, and interpreting services.

SPECIALLY DESIGNED INSTRUCTION

For most students with disabilities, “specially designed instruction” is defined as involving intensive, relentless, structured, appropriately paced instruction, in small groups in which each student’s progress is monitored frequently (Kauffman & Hallahan, 2005). According to Kauffman and Hallahan, all of these characteristics should usually be more evident in special education than is typically the case in general education. Intensive instruction translates into more teacher instructional time and more opportunities for students to respond to the instruction and more time to practice and review what they have learned. Relentless instruction involves repeating this sequence or parts of this sequence more often than is typically done with non-disabled students. Structured instruction refers to teachers being more directive, instituting more explicit rules, and providing more frequent consequences for appropriate or inappropriate behavior. The pace of the instruction in special education is tailored more to the needs of the student and is often slower, with teachers waiting for a longer period of time for a response after querying the student. Instruction in small groups facilitates the intensity, relentlessness, structured nature, and the individualized pace of instruction. Moreover, specially designed instruction means that a student’s progress in learning is monitored frequently, often several times per week.

In addition to these general principles of instruction that apply to most students with disabilities, there are some that apply to specific categories of special education students. For example, for students with blindness or low vision, the “specialized designed instruction” may take the form of reading materials in Braille, large print, or audio recordings, and instruction in the use of a cane for mobility. For students who are deaf or hard of hearing, the instruction may involve sign language or hearing aids. Additionally, for students with emotional or behavioral disorders, instruction may require highly structured classrooms and teaching routines and use of functional behav-

ioral assessment (FBA) and positive behavioral intervention and support (PBIS). FBA involves determining what factors help to set off and maintain inappropriate behaviors. And PBIS emphasizes “rewarding positive behavior, to make problem behavior less effective, efficient, and relevant and to make desired behavior more functional” (Hallahan, Kauffman, & Pullen, 2009, pp. 163–164).

SPECIAL EDUCATION CATEGORIES

Students served by special education fall into 13 disability categories. In order of prevalence they are learning disabilities, speech or language impairments, mental retardation, emotional disturbance, other health impairments (including attention deficit hyperactivity disorder), multiple disabilities, autism, orthopedic impairments, hearing impairments, developmental delay, visual impairments, traumatic brain injury, deaf-blindness. The federal government has provided definitions for each of these categories in order to give guidance to schools in finding students eligible for special education services.

Learning Disabilities. Students with learning disabilities are by far the largest category of special education, comprising between 5 and 6 percent of the school-age population and nearly half of all students identified for special education services. Although its historical roots can be traced back to work done in the 1800s in Europe (Hallahan & Mercer, 2002), learning disabilities as a condition and as a discipline was not formally recognized until the 1960s and 1970s. A major reason for the eventual recognition of learning disabilities as a condition warranting special education services came from parents and professionals who pointed out that there were many students who, although not scoring low enough on intelligence tests to qualify as mentally retarded, were nevertheless still displaying learning problems, especially in reading.

The federal definition of learning disabilities is as follows:

General The term “specific learning disability” means a disorder in one or more of the basic psychological processes involved in understanding or in using language, spoken or written, which disorder may manifest itself in an imperfect ability to listen, think, speak, read, write, spell, or do mathematical calculations.).

Disorders Included Such term includes such conditions as perceptual disabilities, brain injury, minimal brain dysfunction, dyslexia, and developmental aphasia.).

Disorders Not Included Such term does not include a learning problem that is primarily the result of visual, hearing, or motor disabilities, of

mental retardation, of emotional disturbance, or of environmental, cultural, or economic disadvantage (Individuals with Disabilities Education Act Amendments of 1997, Sec. 602(26), p. 13.).

Speech or Language Impairments. Speech impairments include disorders of articulation, fluency, and/or voice (American Speech-Language-Hearing Association, 1993). Articulation disorders often result from neuromuscular abnormalities resulting in omission, substitution, or distortion of speech sounds. Fluency refers to being able to produce smooth speech flow. Disorders of voice include such characteristics as abnormal pitch, loudness, or resonance.

Language impairments can include problems in production and/or comprehension that violate the rules of language pertaining to phonology, morphology, syntax, semantics, or pragmatics. Phonology rules govern how speech sounds are sequenced. Morphology refers to parts of words that indicate such factors as verb tense and plurals. Syntax involves word order that reflects proper grammar. Semantics refers to the meanings of words and sentences, and pragmatics involves using language for social purposes.

Mental Retardation. Most professionals use the definition of mental retardation provided by the American Association on Intellectual and Developmental Disabilities (AAIDD): “Mental retardation is a disability characterized by significant limitations both in intellectual functioning and in adaptive behavior as expressed in conceptual, social, and practical adaptive skills. This disability originates before age 18” (AAMR Ad Hoc Committee on Terminology and Classification, 2002, p. 1). The AAIDD considers the following five points as crucial to understanding the context of the definition:

1. Limitations in present functioning must be considered within the context of community environments typical of the individual’s age peers and culture.
2. Valid assessment considers cultural and linguistic diversity as well as differences in communication, sensory, motor, and behavioral factors.
3. Within an individual, limitations often coexist with strengths.
4. An important purpose of describing limitations is to develop a profile of needed supports.
5. With appropriate personalized supports over a sustained period, the life functioning of the person with mental retardation (intellectual disability) generally will improve. (AAMR Ad Hoc Committee on Terminology and Classification, 2002, p. 1).

Emotional Disturbance. There is considerable controversy concerning the definition of emotional disturbance, which stems from the relatively subjective nature of the condition. In fact, even though the federal government uses the term emotionally disturbed, there are many professionals who prefer the term *emotional or behavioral disorders* because it more accurately conveys the socialization problems these students exhibit.

With respect to definition, many authorities agree on the following three features of emotional or behavioral disorders:

Behavior that goes to an extreme that is not just slightly different from the usual;

A problem that is chronic one that does not quickly disappear; and

Behavior that is unacceptable because of social or cultural expectations (Hallahan et al., 2009).

Other Health Impairments. According to the federal definition, other health impairments (OHIs) are medical conditions, such as asthma, diabetes, epilepsy, sickle cell anemia, which impair to such a degree that they adversely affect a student’s educational performance. The key to the definition is that the condition must interfere with the student’s educational performance. For example, not all students who have asthma have it to such a degree that it affects their ability to function in school.

Students with attention deficit hyperactivity disorder (ADHD) are also included in the federal government’s category of OHI. The American Psychiatric Association (2000) recognizes three types of ADHD: (1) ADHD, predominantly inattentive type; (2) ADHD, predominantly hyperactive-impulsive type; (3) ADHD, combined type.

The reason behind the decision to place ADHD in the OHI category is an interesting lesson in disability advocacy and politics (Hallahan et al., 2009). In the late 1980s and early 1990s, parents of affected children lobbied intensely for ADHD as a new category of special education. Many surmise that the U. S. Department of Education was worried about creating yet another category, especially one that could potentially attract large numbers of students. Therefore, in 1991, they came up with the compromise of stating that students with ADHD could receive special education services if they were identified as having OHI, i.e., had a condition that interfered with their educational performance, thus leaving open the possibility that some students with ADHD would not meet the criteria of OHI because their educational performance was not adversely affected.

Multiple Disabilities. The multiple disabilities category consists of students who have two or more disabilities, “the combination of which causes such severe educational problems that they cannot be accommodated in special education programs solely for one of the impairments” (34 CFR, Sec. 300 [b](6)).

Autism. Many authorities in the early 2000s consider autism to be one of several similar conditions that fall on a spectrum, hence the term *autism spectrum disorders*. The conditions on the spectrum share impairments in three areas: (1) communication skills, (2) social interactions, and (3) repetitive and stereotyped patterns of behavior (Strock, 2004). Classic autism and Asperger syndrome are the most common conditions. Whereas students with autism have relatively severe deficits in all three areas plus severe cognitive deficits, those with Asperger syndrome generally have less severe deficits in all three areas, with their major problem lying in the area of social interactions and some having very high intelligence.

Orthopedic Impairments. Orthopedic impairments include physical disabilities of the muscles and/or bones that negatively affect school learning. Two examples are muscular dystrophy (a hereditary condition resulting in muscle fiber degeneration) and juvenile rheumatoid arthritis.

Hearing Impairments. Students with hearing impairments fall into two categories: those who are deaf and those who are hard of hearing. How one differentiates between the two depends on whether one adopts a physiological or an educational orientation. A physiologically based definition relies on the measurable degree of hearing loss, with those having an impairment of 90 decibels or greater being deaf (0 dB is the level at which the average person can hear the faintest sound). An educationally based definition focuses on the ability to process linguistic information, with deafness indicating that the person cannot process linguistic information through audition even with a hearing aid (Brill, MacNeil, & Newman, 1986).

Developmental Delay. For many infants and preschoolers, it is often difficult to determine whether they have a true disability or have a temporary delay in maturation. In addition, it is sometimes difficult to determine the exact nature of very young children’s disability. For these reasons, professionals are often reluctant to make a clinical diagnosis and, instead, refer to them as having a developmental delay.

Visual Impairments. Like hearing impairments, visual impairments are divided into two groups based on severity: blindness and low vision. Additionally, like hear-

ing impairments, these two groups are defined differently according to whether one uses a physiological versus an educational approach. A physiological orientation (also referred to as the legal definition because it is used to determine certain government benefits) relies on measurement of visual acuity and field of vision. Visual acuity of 20/200 (normal acuity is 20/20, being able to see at 20 feet what a person with normal vision sees at 20 feet) or less in the better eye, even with correction (e.g., eyeglasses), or visual field of less than 20 degrees qualifies an individual as legally blind. Those having visual acuity between 20/70 and 20/200 are referred to as having low vision or being partially sighted. The educational definition focuses on mode of reading, with those needing to use Braille being considered blind, and those who can read print, even with magnifying devices or large-print books, being considered as having low vision or being partially sighted.

Traumatic Brain Injury. In 1990, the federal government added students with traumatic brain injury (TBI) to the list of those eligible for special education services. This decision was in recognition of the fact that TBI occurs much more frequently than was previously thought. For example, estimates are that about one million children and adolescents receive head injuries each year, with 15,000 to 20,000 incurring lasting effects (Council for Exceptional Children, 2001). TBI refers to trauma to the brain caused by an external force that results in behavioral dysfunction. Such injuries can be open head injuries (i.e., penetrating head wounds) or closed head injuries (i.e., damage caused by internal compression or shearing motion inside the head) (Adelson & Kochanek, 1998).

Deaf-Blindness. Basically, students with deaf-blindness meet the educational definitions of both deafness and blindness. The vast majority of students with deaf-blindness also have one or more other disabilities, such as mental retardation. Deaf-blindness can result from (a) prenatal causes, such as rubella, (b) postnatal causes, such as meningitis, or (c) genetic/chromosomal syndromes (Hallahan et al., 2009).

HISTORY OF SPECIAL EDUCATION

The history of special education reveals a pattern characterized by alternating periods of progress and optimism and regress and pessimism. In spite of these fluctuations, overall special education has progressed from a relatively primitive state to its present-day robust status as a viable service option in public schools and as a field of scientific inquiry. Special education history is presented below in four time periods, starting with its birth in the late eighteenth and early nineteenth centuries.

LATE EIGHTEENTH AND EARLY NINETEENTH CENTURIES.

Historians of special education usually trace its roots back to the end of the eighteenth century and beginning of the nineteenth century (Hallahan et al., 2009; Kauffman, 1981). Prior to the French and American Revolutions, care for people with disabilities came largely in the form of asylums, created almost as much to protect the larger society from those considered *idiotic* or *insane* as to protect those housed within the institutions. With the revolutions, however, came principles of democracy and egalitarianism. Fueled by this idealism, many European and American physicians, clergymen, and other reformers tackled the issue of rehabilitating and educating children with a variety of disabilities.

Jean-Marc-Gaspard Itard (1775 1838) is generally credited as being the creator of many of the basic instructional principles upon which special education is built. A French physician, Itard was a specialist in deafness. In fact, it was his specialization in deafness that serendipitously led to his groundbreaking work with Victor, the “wild boy of Aveyron” (Lane, 1984). Found wandering in the forest in 1801, Victor was brought to the National Institution for the Deaf because he was thought to be deaf. Itard, who worked at a nearby hospital was called to the Institute to attend to a resident who had broken his leg on the very day that Victor arrived. Itard saw in Victor the opportunity to demonstrate that intensive instruction could ameliorate even the most intractable learning difficulties. Although Itard was not able to cure Victor and, in fact, considered his efforts largely a failure, others after him considered Victor’s progress to be quite remarkable.

Eduoard Seguin (1812 1880), along with other students of Itard, carried forward many ideas that served as the foundation of special education: individualized instruction, careful sequencing of instruction, stimulation of the senses, careful structuring of the educational environment, immediate reward for correct performance, instruction in functional skills for independence, and an assumption that all children can make some progress (Hallahan et al., 2009). Seguin established the first known school to serve mentally retarded children in France in 1839 before immigrating to the United States. In 1866, he published *Idiocy* and its treatment by the physiological method, which is often cited as the first textbook on instruction for persons with mental retardation.

In addition to Seguin, several other reformers were influential in establishing educational programming for students with disabilities in the United States. The physician Samuel Gridley Howe (1801 1876), who had been the one inviting Seguin to the United States, helped establish the first school for the blind in 1832 in Water-town, Massachusetts, the Perkins School for the Blind.

The minister Thomas Hopkins Gallaudet (1787 1851), after visiting European educators of the deaf, founded the first residential school for the deaf in the United States in 1817 in Harford, Connecticut. In 1841 the social crusader Dorothea Dix (1802 1887) lobbied state and federal legislatures to provide funding for asylums for the insane.

LATE NINETEENTH CENTURY

Much of the optimism and interest in quality care that characterized the early part of the century began to wane in the late nineteenth century (Kauffman, 1981). Depressing economic conditions in the aftermath of the American Civil War (1860 1865), combined with an influx of immigrants and rapid industrialization and urbanization, led to a decrease in interest in educating and rehabilitating those with disabilities.

But even in the face of dwindling interest and resources, several positive developments occurred, including Congress establishing a U. S. Department of Education, special classes and day schools for children who were deaf, the addition of a Department of Special Education in the National Education Association, and special education teacher training programs usually housed in institutions for those with disabilities. It was during this time, too, that numerous professional organizations sprung up for those working with students with disabilities.

But counteracting these positive developments, the close of the nineteenth century witnessed a growing pessimism about what could be done for students with disabilities, especially those who were mentally retarded. The prevailing professional opinion was that mental retardation was incurable and that the most that could be done was to provide protection from and for retarded individuals by housing them in large institutions.

EARLY TWENTIETH CENTURY

The early twentieth century brought mostly positive developments for students with disabilities, with a smattering of negativism, especially toward those with mental retardation. During this time, the eugenics movement gained influence. Henry H. Goddard’s *The Kallikak Family: A Study of the Heredity of Feeble-mindedness* in 1912, purportedly showing the hereditary spread of mental retardation, fueled the passage of legislation in several states to sterilize residents in institutions of mental retardation. Interestingly, later examination revealed strong evidence that he fabricated or altered much of his so-called data (Smith, 1985).

During this time, some of the more progressive public schools began to offer special education classes and resource rooms for students with various disabilities. Elizabeth Farrell (1870 1932), a New York City special education teacher, advocated for the establishment of

classes for students with disabilities. In 1922 she helped found the Council for Exceptional Children, which remained into the early 2000s as the major professional organization for educators of students with disabilities. With the spread of these programs, special education began to be recognized as part of the curricular offerings in school systems.

This period also saw the emergence of many issues concerning education of students with disabilities that persist into the 21st century. For example, there were vigorous debates in the professional literature about segregation versus mainstreaming of students with disabilities, early identification and prevention of disabilities, more federal aid for special education services. In short, the stage was being set for special education to become a discipline of study.

LATE TWENTIETH CENTURY

One of the most, if not the most important development of the late 1900s was the emergence of parent groups and organizations. For example, the National Association for Retarded Children (subsequently called The Arc) was founded in 1950 and the Association for Children with Learning Disabilities (later called the Learning Disabilities Association of America) was founded in 1963. Such organizations were instrumental, along with professional organizations, in lobbying for legislation and services for students with disabilities.

The end of the 20th century was a time of increased expansion of special education research and services. In the research domain, the federal government funded research that generated an expanding body of literature on best practices in identification and intervention for students with disabilities. These competitive research grant programs focused on individual researchers or small teams of researchers as well as large, interdisciplinary research centers. Additionally, personnel preparation grants helped fill the growing need for pre-service and in-service special education teachers, as well as university-level teacher educators.

During this time, too, several pieces of landmark legislation were passed that mandated special education as a civil right for children with disabilities and their families. This legislation, discussed in the following section, established special education as a major piece of the educational landscape in U.S. K-12 schools and universities.

RELEVANT LEGISLATION

Beginning in 1975 and continuing into the 21st century, federal legislation has worked to define the needs of special students and through laws to design ways of serving this population.

Public Law 94-142. The 1975 Education for All Handicapped Children Act (PL 94 142) was a groundbreaking law that established the fundamental parameters of how special education services are defined and implemented in the United States. Key provisions such as a free appropriate public education (FAPE), individualized education programs (IEP), least restrictive environment (LRE), and procedural safeguards (such as due process procedures) defined in the original statute remained primary to the law in subsequent reauthorizations.

Prior to the passage of PL 94 142, many children and youth with disabilities were excluded from public schooling. For the majority of those students, that meant lack of access to appropriate assessment, education, rehabilitative services, and community support. Other federal legislation laid the groundwork for PL 94 142, but these statutes did not wield the same power in terms of firmly establishing the rights of individuals with disabilities access to public education. Notable legislation includes the Training of Professional Personnel Act of 1959 (teacher training for working with individuals with mental retardation), Teachers of the Deaf Act of 1961 (teacher training for working with individuals who are deaf or hard of hearing), the Elementary and Secondary Education Act of 1965 (funding for the education of children with disabilities), and the Handicapped Children's Early Education Assistance Act of 1968 and the Economic Opportunities Amendments of 1972 (establishment of early childhood programs for children with disabilities). These laws helped to articulate instructional practices specific to the needs of students with disabilities and establish models for teacher training that would be included in PL 94 142.

Since 1975 several substantive changes have been made to the law through the reauthorization process. The 1986 reauthorization extended FAPE to include children ages 3 to 5 and established Early Intervention Programs (EIP) and the Individualized Family Service Plan (IFSP) for children ages from birth to 3 years.

More significant changes occurred in the 1990 reauthorization. First, the law was renamed the Individuals with Disabilities Education Act (IDEA). The title change reflected three important points. First, the reach of the law expanded (birth to age 21) with the term "individuals" replacing "children." Second, people-first language "individuals with disabilities" replaced "handicapped children" to emphasize the individual nature of disability—people with disabilities should not be defined by their disability and individuals with the same disability will demonstrate great diversity. Third, the term "disability" replaced "handicapped" to more accurately define the population served. The 1990 reauthorization also included the provision of transition services for students,

created new categories of autism and traumatic brain injury, and re-crafted the language of LRE to place greater emphasis on the need for students with disabilities to receive education with their non-disabled peers.

The 1997 reauthorization extended this LRE position by including specific language that students with disabilities should have “access to the general education curriculum” (PL 105 17). The 1997 reauthorization also included more explicit guidelines regarding disciplinary procedures for students with disabilities. Specifically, the law recommended the use of FBA, discussed earlier, in order to provide preventative instruction or conditions to promote pro-social or desired behaviors. Taken together the reauthorizations of IDEA that occurred between 1986 and 1997 served to strengthen the core mission of the law and provide increased clarity on who is served under the law and what practices should surround the development of special education.

The Role of the Federal Government in Education. To understand how IDEA and other federal statutes affect local educational decision-making, it is important to examine the relationship between the federal government and the fifty states. The U.S. Constitution does not allocate specific power to the federal government in terms of education. As a result, states determine the policies, procedures, and requirements school districts must follow. The federal government does not possess the power to establish a national curriculum or set national standards for performance. From time to time, however, the federal government passes legislation that allows for the provision of funds to states for the purpose of improving education. Examples include grants to build infrastructure (e.g., land grants) or grants to improve educational outcomes for children in poverty (e.g., Head Start). When states accept these funds, they must also uphold the specific requirements associated with that funding stream. Even though the funding provided by the federal government has historically not exceeded 10% of a state’s education budget, states do rely on these funds (Yell & Drasgow, 2005). This relationship supplies the power to the federal government to shape and influence education.

Standards and Special Education. In 1983, under the leadership of the Secretary of Education, the Commission on Excellence in Education issued the *Nation at Risk* report. Many viewed the report as a wake-up call to the mediocre levels of student achievement in the country. One recommendation contained in the report urged the development of challenging, measurable academic standards. The push for standards came again in 1989 when President George H. W. Bush convened the fifty governors at the first National Education Summit. Many of the goals and priorities established as a result of the

summit became a part of the educational plans of President Bush and then of President Clinton.

In 1994 President Clinton reauthorized the Elementary and Secondary Education Act of 1965 (ESEA). The reauthorized act, renamed Improving America’s Schools Act, reflected the standards framework recommended by the *Nation at Risk* report and articulated in President Bush’s America 2000 and President Clinton’s Goals 2000: Educate America Act. This reauthorization established a precedent for an expanded role of government in education and lay the groundwork for the next reauthorization, which would prove to be both controversial and far-reaching.

No Child Left Behind Act. The 2001 reauthorization of ESEA brought yet another title change for the law. The No Child Left Behind Act of 2001 (NCLB), under President George W. Bush, adopted many of the principal features (e.g., academic standards, accountability, and adequate yearly progress) included in the 1994 reauthorization of ESEA (Yell & Glasgow, 2005). The departure from prior educational legislation came in the form of demands to bring all students up to standards within a certain time frame and the establishment of sanctions for schools that did not perform. In essence, NCLB was the first instance of federal educational legislation that had the power to enforce itself. NCLB passed by an overwhelming bipartisan majority in both the House and Senate, yet shortly after its passage political schisms in regard to implementation of the law occurred.

The confluence of standards/accountability represented in NCLB and the increasing emphasis on access to the general education curriculum in IDEA resulted in a federal position on the education of students with disabilities that looked more similar to general education policies than ever before in the history of special education. Several provisions in NCLB had direct influence on the reauthorization of IDEA in 2004 and on the ensuing instructional practices for students with disabilities. Specifically, NCLB required (a) accountability for results, including the results of students from identified subgroups (i.e., students with disabilities, ethnic and racial minorities, students who are economically disadvantaged, and students who are limited English proficient); (b) the use of instructional practices based upon scientifically based research; and (c) that necessity that all students be taught by a teacher who meets the federal definition of “highly qualified.” The 2004 reauthorization of IDEA included NCLB’s definition of highly qualified special education teacher and a similar requirement for the use of materials and practices based upon scientifically based research.

Under NCLB, states were required to report disaggregated data on the various sub-groups, including students with disabilities. Although these data led to greater transparency in regard to the educational outcomes of students with disabilities and greater accountability for demonstrating educational progress, the fact that at least 95% of students with disabilities were required to participate in the state-wide assessments caused concern for some. In addition, only 2% of students with disabilities could participate in modified achievement standards or alternate tests. Questions related to which assessments (grade-level or ability-level), accommodations or supports, and populations of students under IDEA should be selected challenged states' initial implementation of the law. NCLB's highly qualified teacher requirement also proved challenging in its implementation.

In addition to incorporating the language and fundamental principles of NCLB, IDEA 2004 included several other important provisions that would have direct influence on the identification of and instructional practices for students with disabilities. For example, the concept "universal design" was used throughout the amendments to underscore the importance of selecting materials, methods, and assessment techniques and technologies that allow for access by a wide-range of students. For teachers, universal design means selecting instructional strategies that provide benefit to a range of learners—from students with disabilities to high-achieving students—or creating assessments that allow a range of students to demonstrate knowledge of high academic standards.

Two other changes to IDEA 2004 reflected the trend towards unifying general education and special education practices. These changes included providing more flexibility to schools in terms of the discipline of students with disabilities and the removal of short-term objectives on the IEP for the majority of students with disabilities. In terms of discipline, the law shifted the burden of proof in manifestation determination reviews to the parents and made it easier for schools to remove children for disciplinary infractions other than weapons, drugs, or dangerous behavior. The removal of short-term objectives for all students, except those who participate in alternate assessments and follow alternate standards (less than 1% of students with disabilities), reflected the increasing emphasis on participation in general education standards and accountability.

Perhaps the most significant addition to IDEA 2004, though, was the inclusion of additional procedures for the identification of students with specific learning disabilities. States were no longer required to use a "severe discrepancy" between achievement and intellectual ability as an identifying factor. In addition, states could now allow processes that measured a "child's response to

scientific, research-based interventions" as a gauge for identification. Commonly referred to as *response to instruction* or RTI, this provision dramatically changed the language (and some would argue, practice) of special education. Special educators would differentiate between "core instruction," the instruction received by the majority of students in general education, and "levels of intervention," the qualitatively different instruction that was delivered to students not making progress in the core program. These levels of intervention were not necessarily delivered in settings outside the general education classroom but could be.

Other Influential Laws. Two other laws directly influence the education of students with disabilities: Section 504 of the Rehabilitation Act of 1973 (Section 504) and the Americans with Disabilities Act (ADA) of 1990. Both Section 504 and ADA are civil rights acts that protect qualified individuals with disabilities from discrimination of benefits or services on the basis of disability. These nondiscrimination laws apply to any organization receiving federal financial assistance, which would include public schools. Although 504 and ADA have much in common with IDEA, the fundamental purposes of these laws differs from the charge of IDEA.

The purpose of Section 504 is to create equal opportunity for students with disabilities through the elimination of barriers or the provision of accommodations for equal access. In other words, for students who can be successful the general education classroom with the provision of minor instructional accommodations or structural changes, Section 504 may be the only law these students need. In contrast, the intent of IDEA is to provide specialized services and supports that differ in some way from the education received by students without disabilities. Students with disabilities who require more intensive instructional modifications or supports (regardless of placement in the general education setting or in a more restrictive setting) would benefit from the protections and services provided under IDEA.

To qualify under Section 504, students must (a) have a physical or mental impairment that substantially limits a major life activity (e.g., learning, walking, seeing, hearing), (b) have a record of an impairment, or (c) be regarded as having an impairment. Some students with disabilities who would not qualify under one of IDEA's 13 disability categories may qualify under Section 504's broad definition of disability. Section 504 protections can be important for students with communicable diseases, chronic health conditions, and students with ADHD who would not or choose not to qualify under IDEA but are in need of instructional supports. Unlike IDEA, schools do not receive funding for Section 504 services, but schools are under the same federal obligation

to comply with the law. As such, some schools are hesitant about offering such services or making Section 504 information widely available to parents. Yet, Section 504 protections must be in place and available for interested parents, teachers, and student advocates.

The Americans with Disabilities Act reflects similar language (e.g., definition of disability) and objectives as Section 504 but applies to a broader spectrum of organizations—public transportation, employment, and state and local government. Basic provisions under ADA require organizations to provide “reasonable accommodations,” physical access (e.g., ramps for individuals who use wheelchairs), and freedom from discrimination based upon disability status. Both ADA and Section 504 are administered by the Office of Civil Rights and are considered identical for the purposes of compliance monitoring.

RESPONSE TO INTERVENTION IN SPECIAL EDUCATION

In the context of increased accountability, greater emphasis on the use of scientifically based practices, and a focus on high standards for students with disabilities, the landscape of special education has become simultaneously more uncertain and more articulated. One example of this contradictory position occurred in the introduction of the concept of responsiveness to intervention (RTI). With the passage of the 2004 amendments to IDEA, RTI was established as an alternative to the use of ability-achievement discrepancy as a means for identifying learning disabilities. The law also positioned RTI practices as a tool for ensuring the systematic delivery of research-based interventions to all students not making appropriate gains in the general curriculum. Many heralded the inclusion of RTI in the 2004 statute, yet questions remained regarding issues of implementation and scale (Hallahan & Cohen, *in press*; Fletcher, Lyon, Fuchs, & Barnes, 2007). Specifically, some in special education have questioned whether the distinction between specialized services and general education practices would be blurred and result in less intensive supports for students with disabilities, while others felt that the move would result in even clearer articulation of levels of instruction and the identification of specific interventions for students with disabilities.

In 2005 the National Joint Committee on Learning Disabilities (NJCLD), consisting of representation from the major professional organizations devoted to learning disabilities, issued a report on RTI in which it identified potential strengths and highlighted areas of future research. In underscoring the potential of RTI methodologies, the NJCLD noted the promise of early and/or preventative remediation, the application of high-quality interventions, and the ability to yield a “true population”

of students with learning disabilities. The underlying assumption of RTI is that the application of effective instructional methodologies will result in the majority of students making satisfactory gains while other students will fail to respond to the instruction. These students who continue to struggle while receiving high-quality instruction are students with learning disabilities. Therefore, these students require the more intensive, specialized instruction provided under IDEA.

One example of an RTI model is as follows:

Implementation of Tier 1 (high-quality general education instruction) with universal screening to identify at-risk students and the use of regular progress monitoring.

The provision of Tier 2 interventions (typically 8–12 weeks in duration) provided within the general education classroom for the identified at-risk students.

Continual progress monitoring is provided in order to determine responsiveness to the intervention.

Finally, students failing to respond to Tier 2 are referred for eligibility for special education in Tier 3, which consists of more individualized, intensive tertiary interventions, thus defining Tier 3 interventions as special education.

RESPONSE TO INSTRUCTION IN SPECIAL EDUCATION

Instructional practices for students with disabilities take into consideration (a) the unique characteristics of the learner, (b) the nature of the content or skill to be taught, and (c) the intersection of those characteristics and content. Given the fundamental role both learner and content play in the development of special education practices, special educators need to be well-versed in both the characteristics of the students they serve and the nature of the content to be taught. Some characteristics may be unique to a category of disability identified under IDEA, such as social impairments associated with autism, or the characteristics may cut across a range of categories, such as difficulty with memory and information processing associated with students with learning disabilities and students with mental retardation.

Fundamental to the practice of designing specialized instruction is task-analysis—breaking down the content of instruction to all the requisite skills and constructs. Identification of requisite skills and constructs allows teachers to select appropriate strategies, scaffolds/supports, and accommodations or modifications to meet the unique needs of the individual student. Three common elements to the implementation of effective special education instruction are: (a) explicit, systematic instruction, (b) continual progress monitoring, and (c) behavioral analysis and supports.

As stated previously, the hallmark of special education instruction is the delivery of intensive, relentless instruction with frequent opportunities for student response. Research on effective practices in special education has demonstrated the power of explicit instructional practices such as direct instruction fast-paced, well-sequenced, highly focused instruction with high student responses rates and strategy instruction that focus on organization, elaboration, or generative thinking for students with disabilities (Gersten, Schiller, & Vaughn, 2000). Key features of explicit instruction include careful sequencing and organization, enhancing student motivation through early and frequent success, and scaffolding (decreasing levels of support to foster mastery). Specific instructional strategies that reflect these principles and have been demonstrated as effective for students with disabilities include: structured peer-tutoring (Fuchs, & Fuchs, 1998), direct instruction (Adams & Engleman, 1996), mnemonic instruction (Mastropieri, Sweda, & Scruggs, 2000), and learning strategies (NICHY, 1997).

Progress monitoring was first introduced in the field of special education in the 1970s as data-based program monitoring and later as curriculum-based measurement (Deno, 2003). The underlying concept was that teachers would use repeated measures of student performance in order to determine the effectiveness of instruction and then make needed changes to their teaching if students were not responding. Incarnations of curriculum-based measurement/progress monitoring as of 2008 involve tracking student performance over time and instructional decision-making using predetermined targets or benchmarks. Decades after its inception the fundamental constructs of progress monitoring and instructional decision-making based upon data have become paramount in the field of special education. Further, what began as a special education practice came in time to influence the conceptualization of effective instruction for all students.

Another component of effective special education is the application of behavioral analysis for the purpose of determining appropriate supports, frequently referred to in special education as *positive behavioral supports*. Meta-analyses, statistical procedures that measure the overall efficacy of a strategy or approach, have demonstrated the power of positive behavioral supports to reduce undesirable behaviors and increase pro-social or desired behaviors (Gersten, Schiller, & Vaughn, 2000). The development of positive behavioral supports begins with an analysis of environment and student behavior. The environment includes all elements associated with the delivery of instruction (e.g., instructional methods or strategies used, materials selected, physical design), and student behavior includes communication, social interactions, and maladaptive responses. Special educators or IEP teams collect data on the behavior(s) of concern in an attempt to

determine the function or purpose of the behavior. Analysis of the data leads to the development of a hypothesis of the function of the behavior. The educator or team then identifies teaching procedures intended to (a) reduce the undesirable behavior and (b) teach a more acceptable or adaptive behavior. Data continue to be collected in order to determine the efficacy of the supports and instruction selected.

In summary, the basic principles that served as the foundation of special education remain a vibrant part of the instruction of students with disabilities today. Research in the field of special education has served to refine and improve specific practices such as progress monitoring, the delivery of instruction, cognitive strategy instruction, functional behavioral analysis and positive behavioral supports, and the identification of a range of disabilities. Legislation in the early 2000s and to come will continue to influence and shape the context of the education of students with disabilities, but fundamental principles of individualization, remediation, and measured-growth will remain an essential part of what special educators do.

SPEECH AND LANGUAGE IMPAIRMENTS

According to the U.S. Department of Education, in 2006 there were 1,486,960 children with diagnoses of speech and language impairments in U.S. public schools. Even greater numbers of children had speech and language

impairments associated with other diagnoses such as learning disabilities, autism spectrum disorders, or hearing impairment. The school-based speech and language pathologist (SLP) works to promote the functional skills of children affected by speech and language impairments and “to provide support in the general educational environment for students with communication handicaps to facilitate their successful participation, socialization, and learning” (American Speech-Language-Hearing Association, ASHA, 2000, p. 11). The impact of the impairment on the child’s educational functioning is the paramount consideration.

DEFINITIONS

Speech and language impairments may be classified by *symptomology*, the particular aspects of speech or language that are affected; *specificity*, whether or not the impairment is part of a broader deficit; and *etiology*, whether the impairment is developmental or acquired. In the following sections, these classifications are defined.

Speech. Children affected by speech impairment most often have deficits in producing the sounds of the language as compared to their same-age peers. They may leave out sounds (e.g., tar for star) or substitute one sound for another (e.g., cawot for carrot). In some cases the child does not understand the rules that govern the production and combination of speech sounds, which is commonly referred to as phonological impairment. In other cases, the root of the problem is motoric, which is commonly referred to as articulation impairment. Often, because the roots are not completely understood, the terms are used interchangeably. Articulation/phonological impairment is the single most frequent diagnostic category represented on the caseload of the school SLP (ASHA, 2006).

Speech impairments broadly defined also include abnormal voice, nasal resonance, and fluency (ASHA, 1993). Children with voice problems present with deviations in pitch, quality, or loudness of their speech as compared to other children of their same sex and age. Nasal resonance problems involve either hypo- or hypernasality. The former results when a blockage (e.g., swollen adenoids) prevents air from resonating within the nasal cavity during speech. The latter results when the soft palate does not make adequate closure with the pharyngeal wall during production of the oral sounds of the language. The speech of children who stutter is characterized by disruptions in rate and rhythm as well as repetitions of sounds, syllables, words or phrases. Affected children may struggle or tense when they stutter.

Language. Children affected by language impairments have deficits in understanding or expressing words, sentences, or extended discourse in either spoken or written modalities. This deficit may involve problems with semantics, the meaning of language (e.g., understanding the meaningful relationship between the words *animal*, *cat*, and *Tabby*); morphology and syntax, the grammar of language (e.g., inflecting verbs with *ed* to indicate past tense); or pragmatics, the social use of language (e.g., judging the right amount of information to convey to a listener). Childhood language impairments may be referred to as language delays or language disorders. The term *delay* implies slow but typical development whereas *disorder* implies atypical development.

Primary or Secondary Impairment. Developmental speech and language impairments may be primary or secondary diagnoses. Children with primary impairments are otherwise normally developing. The cause of the impairment is usually unknown though central nervous dysfunction is presumed (ASHA, 1997) and, according to Bruce Tomblin and colleagues (1997), such impairments run in families. Children with primary language impairments affecting the oral modality are often said to have specific language impairment; those with primary impairments affecting the written modality are often said to have language learning disabilities, but either diagnostic category can encompass impairments in both modalities. Other children have speech and language impairments that are secondary to another deficit. For example, children with attention deficit hyperactivity disorder may have difficulty planning and organizing discourse as well as problems using language in a pragmatically appropriate manner, whereas children with cerebral palsy may have difficulty pronouncing speech sounds.

Developmental or Acquired Impairment. Most speech and language impairments exhibited by school children are developmental, that is, roots of the problem exist from birth and manifestations of the problem emerge as the child develops and it becomes obvious that the child is slower or atypical compared to peers. In a minority of cases, speech and language impairments are acquired when a child suffers an illness or accident that affects brain function. In these cases, the impairment may be referred to as aphasia. Rhea Paul (2001) summarizes these aphasias as follows. In cases of stroke and traumatic brain injury, children tend to be initially mute but have generally good recovery over time. A stroke, especially one that results in focal damage to the left hemisphere, typically results in long-term but subtle deficits in verbal memory, grammatical complexity, word finding, and reading. Traumatic brain injuries, such as those sustained from falls or car accidents, may result in long-term problems with word

finding, discourse, and pragmatics. Speech motor control may also be compromised. A seizure disorder known as Landau-Kleffner syndrome has its onset in childhood and usually results in permanent impairments in the comprehension and expression of language.

DIAGNOSIS AND ASSESSMENT OF SPEECH AND LANGUAGE IMPAIRMENTS

In school settings, diagnosis and assessment are typically accomplished by teams of professionals who collaborate to make decisions regarding a given child's strengths and weaknesses. When speech and language development is a potential area of weakness, the SLP will be part of that team. The diagnosis of speech and language impairments is, in general, a two-pronged process. First, the child is referred for diagnostic testing, usually because a family member or teacher is concerned about his or her ability to function successfully in situations that demand verbal performance. Such situations include expressing basic needs, making friends, communicating in the classroom, taking tests, and learning to read and write. The SLP explores these concerns as well as the child's developmental and educational history via parent and teacher interviews.

Second, via standardized norm-referenced testing, observations in natural settings, and descriptive criterion-referenced assessments (e.g., review of classroom work portfolios, probes of response to intervention) the SLP determines whether the child is functioning more poorly than peers of the same chronological age in one or more domains (e.g., speech, semantics, morpho-syntax, pragmatics) and whether the child is apt to improve functioning in response to various supports. There is no universally agreed upon cut-off score on standardized tests for identifying speech and language impairments. Instead, the decision varies with the extent of the real-life impact, the number of domains affected, and the resources available for intervening on the child's behalf. State codes may establish eligibility criteria as well as recommended amounts of service and service delivery options in school settings (ASHA, 2000).

In cases of secondary impairments, speech and language problems may be one symptom leading to the diagnosis of the primary impairment. For example, late talking may be the first sign that a child is affected by a hearing impairment. In other cases, the primary impairment is diagnosed first and speech and language is monitored because the child is known to be at risk. This situation is illustrated in Down syndrome, an impairment typically diagnosed *in utero*. Children with Down syndrome are known to have particular difficulties with speech-motor control and expressive language development; therefore, they are frequently placed in speech and

language intervention programs as babies. In cases in which speech and language problems are secondary to a deficit that involves mental retardation, the extent of the speech and language problem may be determined relative to mental-age peers (i.e., younger normally developing children) rather than chronological-age peers. In cases of acquired language impairments, the child may also be compared to his or her own previous level of functioning, if that is known.

CHARACTERISTICS OF SPEECH AND LANGUAGE IMPAIRMENTS BY DIAGNOSTIC CATEGORY

Implicit in the above definitions is the enormous variability between children with speech and language impairments. One child may have a very mild deficit affecting only a few speech sounds whereas another may have a very severe deficit that prevents oral language altogether. In between are numerous other profiles, some of which are predictable if the roots of the impairment are known. For example, Laurence Leonard (1998) notes that children with specific language impairment are typically late to acquire first words. Their acquisition of grammar lags even further behind (in English this is often manifested as omission of inflections on verbs across an extended developmental period). Abbeduto and Hagerman (1997) note that children with fragile X syndrome, especially boys, often present with variability in rate of speech, delays in the development of words and word inflections, and perseverations of words during discourse. Finally, Krista Wilkinson (1998) notes that children with autism spectrum disorders have difficulty establishing and maintaining joint attention with communicative partners. Their speech may sound monotonous and the information that they convey via speech may strike the listener as odd or tangential. Although researchers can make generalizations like these for almost any diagnostic category, the value of the exercise is questionable. Two children who share a diagnosis may be less similar than two children with different diagnoses. Moreover, knowing the child's diagnostic category is of limited help in designing an intervention. Instead, the SLP typically meets with more success by selecting goals and strategies based on what is known about the child rather than the diagnosis.

CURRENT INTERVENTIONS AND INSTRUCTIONAL PROCEDURES

In school settings, interventions for children with speech and language impairments are specified by an Individual Family Service Plan (IFSP) for children younger than three or an Individual Educational Program (IEP) for children who are three or more years of age. These plans are mandated by the Individuals with Disabilities Educa-

tion Act of 1997 (IDEA). In the case of a child with or at risk for speech and language impairments, either plan will specify goals for speech and language development and the services and program accommodations necessary to reach those goals. Typically the SLP will set both long-term and short-term goals. If, for example, a long-term goal for the child is to master new grammatical forms, a more intermediate goal might be to learn to use helping verbs and the short-term targets of focus might be *will*, *can*, and *does*.

According to Rebecca McCauley and Marc Fey (2006), to approach these goals, the SLP must determine the context for the intervention (e.g., classroom-based, pull-out group, pull-out individual, self-contained classroom), the intervention agent (e.g., SLP, teacher, peer, parent), and the dosage (e.g., minutes per week). These decisions are made with consideration of the needs of the child, the wishes of the parents, and state codes. The SLP then determines the activities and strategies that will work best for a given child. Activities may include picture naming drills, joint book reading, dramatic play, computerized language comprehension exercises, and writing assignments, to name a few. During those activities, the SLP employs strategies that may include asking the child to listen to or imitate models of correct target productions, to correct mistakes when given feedback, or to respond when given scaffolds such as cues and simplifications of the task. The SLP chooses materials that will provide focused stimulation, that is, those which will allow many opportunities for the child to experience and to practice the target. The SLP may recast, revise, or expand the child's spontaneous utterances as a way to further model targets. When the SLP is not the primary agent of intervention, she serves as a collaborative consultant to teachers, parents, or peers by explaining the goals, activities, and strategies to be used with the child. An additional important component of intervention is on-going reassessment to ensure that the child is making progress; if not, program modification is necessary.

Best practice requires that decisions made about the intervention program are guided by the expertise of the SLP in light of the needs and values of the child and family and the research evidence that demonstrates the utility of various program options. Learning about the child and family is an on-going process that begins with the case-history interviews and observations, continues during the IFSP or IEP process, and grows as the SLP manages the child's intervention. SLPs who adhere to evidence-based practice seek independent confirmation and converging evidence for clinical decisions from the research literature. They evaluate research evidence to ensure that it is characterized by adequate experimental control and that it is free from bias. They determine whether the effects of any reported clinical procedure

are sizeable, relevant to the child in question, and feasible in the school setting (ASHA, 2004).

ISSUES RELATED TO ASSESSMENT AND INTERVENTION

As in any profession, the state-of-the-art in speech and language pathology is dynamic. A number of issues have prompted important changes in service delivery to children with speech and language impairments. Three issues are highlighted below.

Inclusion. The IDEA amendments of 1997 encouraged the participation of children with special needs in the general education curriculum. As a result, children with speech and language impairments are now often assessed and treated, at least in part, within the regular classroom. According to Rhea Paul (2001) and Carol Westby (2006), during curriculum-based assessment, the SLP analyzes the spoken or written features of the student's school work (homework, tests, projects), observes the child's successes and failures during school activities, and tests the utility of various scaffolds for the child's verbal performance during such activities. Curriculum-based intervention requires the SLP to move away from contrived exercises outside the classroom and towards consultant or collaborative roles within the classroom. As consultants to classroom teachers, SLPs suggest modified verbal instructions that enhance comprehension and verbal responding in the moment as well as strategies, materials, and activities that promote improvements in speech and language development over time. As collaborators, SLPs plan and implement lessons along with teachers. In either role, the SLP is concerned with supporting the child's communication in the classroom as well as his or her performance on language-related academic tasks whether they are taking a spelling test or comprehending a social studies text. Curriculum-based practice in schools is highly compatible with a broader emphasis in the field of speech pathology on intervening via purposeful and functional activities in naturalistic settings.

Diversity. According to a 1994 report from the U.S. General Accounting Office, bilingual students learning English as a second language were common in nearly every state. SLPs recognize that differences between communities in dialect or language are to be cherished, not pathologized or stigmatized (ASHA, 1983). Therefore, one of the key roles played by the SLP in increasingly diverse school settings is to help assessment teams distinguish speech and language patterns that reflect the learning of English as a second language from those indicative of true impairments. To make this distinction effectively, IDEA mandates that the child's native language development be assessed. Such assessment is complicated by a

lack of professionals who are familiar with more than a mere handful of the 311 languages reported by the National Virtual Translation Center to be spoken in the United States as well as a lack of standardized tests that are normed for students who are bilingual. The limited availability of appropriate standardized tests represents yet another impetus in the movement towards curriculum-based assessments in naturalistic classroom settings. In cases in which true impairments have been discerned in the bilingual child, intervention is also complicated. For example, as noted by Celeste Roseberry-McKibben (2007), cultural and linguistic differences between the parents and the SLP may impede effective involvement of the family in the intervention. Such challenges may increase as the diversity of the U.S. population continues to grow; however, that growth will surely motivate useful changes in the design of tests and the education of SLPs and other professionals.

Evidence-based Practice. SLPs have long been aware that collecting data from individual children is important for planning interventions and monitoring their success. They have known that keeping current with research in the field is important. What changed with the advent of the evidence-based practice movement in the early 2000s was the emphasis on finding high levels of evidence, evaluating the quality of that evidence, and applying that evidence in decision making for individual children. Various guidelines exist for determining levels of evidence and evaluating quality (ASHA 2004). The SLP can also make use of published systematic reviews and meta-analyses and searchable online databases that summarize findings over multiple studies and include quality appraisals for each. Evidence-based practice is the joint responsibility of clinicians and scientists. As school-based SLPs retool to master evidence-based decision making; scientists must continue to fill gaps in the quantity and quality of available evidence. These joint efforts stand to further enhance the assessment and intervention services provided to school children with speech and language impairments.

STANDARDIZED TESTING

Standardized testing involves using testing instruments that are administered and scored in a pre-established standard or consistent manner. There are two types of standardized testing instruments: *norm-referenced tests* and *criterion-referenced tests* (IRA/NCTE Joint Task Force on Assessment, 1994). The former testing instruments yield scores that compare the examinee's scores to that of a representative sample (the normative group) of same-age or grade peers. The latter type of testing instrument involves comparing an examinee's score to a pre-determined criterion (such as a school curriculum).

Norm-referenced Tests. Academic achievement tests and cognitive tests, commonly referred to as IQ tests, are well known examples of norm-referenced, standardized tests given to individuals. Most norm-referenced test batteries include a manual and/or computerized scoring program that (1) provides information regarding the normative, or standardization, sample; (2) provides information on reliability and validity, (3) provides language and presentation of items administration and scoring information, and (4) provides guidelines for the interpretation of the test results. Norm-referenced test performance is generally summarized as one or more types of scores such as age-equivalence, grade-equivalence, percentile rankings, stanine, scaled scores, indexes, clusters, or quotients (Mercer, 1997). Newer editions of test instruments follow an item-response-theory procedure in their development which can allow for a new type of scores. These scores (called W-, Growth, Change-Sensitive, Growth-Score-Value) allow an examinee's performance to be measured against themselves by establishing the difficulty level of the items.

Criterion-referenced Tests. Criterion-referenced tests are similar to norm-referenced tests in terms of administration, scoring, and format; however, they differ in terms of interpretation. Criterion-referenced test interpretation involves evaluating an examinee's performance in relation to a specific criterion. For instance, if a criterion were "the ability to subtract single digit numbers," the interpretation would involve indicating simply whether or not the student answered the administered subtraction problem items correctly. A norm-referenced test interpretation, however, would involve whether this student

correctly answered more questions compared to others in the normative group. Generally, criterion-referenced performance is summarized as percentage correct or represented as a grade-equivalent score (Weaver, 1990; Witt, Elliot, Daly, Gresham, & Kramer, 1998).

Criterion-referenced tests are sometimes misunderstood. Although these types of test can involve the use of a cutoff score (e.g., the point at which the examinee passes if the score exceeds this number), the cutoff score is not the criterion. Rather, the criterion refers to the content area domain that the test is intended to assess (Witt et al., 1998).

QUALITY OF STANDARDIZED TESTING INSTRUMENTS

The quality, or adequacy, of any standardized testing instrument, whether norm-referenced or criterion-referenced, is directly empirically supported by both reliability and validity studies. Professional testing associations or organizations often publish standards that practitioners can refer to when evaluating the quality of a testing instrument. For instance, in the field of psychometrics, there is a set of standards titled, "Standards for Educational and Psychological Testing" which psychologists and other related practitioners can refer to when interested in the standards of test development or construction, fairness in testing, and testing applications. Additionally, practitioners can learn about the psychometric properties (e.g., reliability, validity) of tests by consulting sources such as *Mental Measurements Yearbooks* and *Tests in Print*, both available from the Buros Institute of Mental Measurements and housed within most major libraries (Mercer, 1997) or *Test Critiques*, available from Pro-Ed Publishers.

ADVANTAGES OF STANDARDIZED TESTING

Using standardized tests to conduct assessments is advantageous for several reasons. First, because standardized tests yield quantifiable information (scores, proficiency levels, and so forth), results can be used in screening programs (e.g., identifying those students in need of further assessment). Second, standardized test results provide information regarding an examinee's areas of strength and weakness. Third, standardized test results allow a student to be compared to age- or grade-peers. Finally, standardized tests can be used to assess students' progress over time (e.g., readministering tests after the application of an intervention or following the institution of a remedial program) (IRA/NCTE Joint Task Force on Assessment, 1997; Witt et al., 1998). The most important advantage of results from a test administered in a standardized fashion is that the results can be documented and empirically veri-

fied. This then allows for the results to be interpreted and ideas about an individual's skills generalized.

DISADVANTAGES OF STANDARDIZED TESTING

Although standardized testing is beneficial in some situations, its use has been criticized, specifically because such measures fail to inform instruction adequately. Standardized administrations may not be possible for some students with disabilities. Some disabled students can take some test in the established standardized way with some accommodations. Some accommodations, however, can become modifications to the trait or concept attempting to be measured. Some other common criticisms or disadvantages of standardized tests are as follows: (1) standardized test items frequently are unrelated to those tasks and behaviors required in the classroom setting, (2) standardized test results reflect behavior or ability that has been measured during a single point in time and, as such, are greatly influenced by noncognitive factors (e.g., fatigue, attention, and so forth); (3) standardized test results do not provide the type of information required for making curricular modifications or instructional change, and (4) standardized administration procedures often prevent the examiner from obtaining useful information regarding the conditions under which the examinee may be able to improve performance (e.g., could a student with a language deficit benefit from clarification of test directions?) (Fuchs & Fuchs, 1986; Haywood & Tzuriel, 1992; Quinto & McKenna, 1977; Tzuriel, 2001; Tzuriel & Samuels, 2000).

ALTERNATIVES TO STANDARDIZED TESTING

Partly due to the criticisms of standardized testing and the need to generate information that can more directly guide instruction, alternatives to standardized testing have arisen. While there are various alternatives, three of the most commonly used alternatives are curriculum-based assessment, dynamic assessment, and alternative, or portfolio-based, assessment approaches.

Curriculum-Based Assessment. Although *curriculum-based assessment* (CBA) falls under the umbrella of criterion-referenced testing, it is thought of as an alternative to traditional, standardized norm-referenced academic testing. Curriculum-based assessment refers to a measurement method that relies on "direct observation and recording of a student's performance in the local curriculum as a basis for gathering information to make instructional decisions" (Deno, 1987, p. 41). CBA has also been referred to as *direct assessment* of the mastery of academic skills, and although models of CBA may differ,

all share the common foundational assumption that one should assess what is taught, or more simply, “test what one teaches.” Typically, CBA approaches involve repeated assessment of specific academic skills (Lentz, 1988). In each academic area, *probes* are developed (e.g., short reading passages, samples of math computation items, and brief spelling word lists, and so forth) and used to collect student performance data. The curricular materials from the examinee’s immediate learning environment are used to develop CBA probes. Given this, CBA provides a structured method for evaluating students’ performances on curricular assignments used in their actual academic setting.

Generally, a student’s responses are evaluated in terms of speed or proficiency, as well as for accuracy. Performance criteria are then developed to determine acceptable levels of student performance or mastery (Witt et al., 1998). Normative sampling is one procedure employed for establishing mastery criteria (Idol, 1993). This procedure involves collecting samples of average or acceptable student performance in the general education setting and using such samples to decide what the absolute mastery criteria should be. In some cases, a referred student may be so far below the levels of acceptable performance that a type of changing criterion design might have to be implemented. This type of design, which would allow the mastery criteria to reflect the classroom average, would permit a lowering of the criteria for subsequent instruction, and then allow the criteria to be made more stringent until the student reached the changed classroom average.

Overall, the basic assumption of a CBA approach is that in evaluating students’ progress in reading and writing, researchers should observe them reading and writing in their academic environment, and should collect such data often so that they can efficiently ascertain whether a student is progressing adequately or falling behind. The ability to generalize from the results of CBA tests is limited.

Dynamic Assessment. *Dynamic assessment* refers to a particular type of learning assessment that involves the use of an active teaching process (Lidz, 1987). The goal of this teaching process is to “modify” an individual’s cognitive functioning and to observe subsequent changes in the examinee’s learning and use of problem-solving strategies. The primary goals of dynamic assessment are to (1) assess a student’s ability to understand principles underlying a problem and to use that understanding to generate a solution, (2) assess the type and amount of teaching necessary to teach a student a specific rule or principle, and (3) identify any cognitive deficits and non-cognitive factors that assist in explaining performance failures and to determine whether such factors can be modified by teaching alone (Lidz, 1987).

Dynamic assessment directly contrasts with static assessment procedures (i.e., standardized assessment), which involve examiners presenting items to examinees without any guidance, assistance, or any other intervention designed to change or improve the examinee’s performance. A static test is usually based on a “question, record, and score” format wherein the examiner presents the question, records the examinee’s response, and awards a prescribed number of points, based on the examinee’s given response.

The difference between static and dynamic assessment approaches stems from the paradigms from which they emerged. Static assessment generally involves “passive acceptance,” wherein a child’s deficits or disabilities are accepted and the environment is modified to help the child work within any identified limitations (Haywood, 1997). In contrast, dynamic assessment is based on “active modification,” wherein a concentrated effort is made to remediate any identified deficit or at least provide the child with compensatory strategies to circumvent the impact of any identified weakness (Haywood & Tzuriel, 1992).

The inherent limitations or inadequacy of standardized tests has motivated, in part, the development of dynamic assessment approaches. Static assessments have been criticized widely. Major criticisms involve the fact that (1) static tests do not provide important information about a child’s learning processes or mediational strategies that can facilitate learning, (2) they do not result in clear recommendations for prescriptive teaching or remedial activities, and (3) they do not focus on noncognitive factors that influence an examinee’s performance on standardized, cognitive assessments. Compared to static assessment, dynamic assessment is intended to provide information about (1) examinees’ overall learning ability and information regarding how they learn, (2) specific cognitive factors that can assist in problem solving and can help the examiner understand potential factors related to academic successes and failures, (3) teaching strategies that seem to work for a given examinee, and (4) non-cognitive factors that exert beneficial or negative influences on cognitive performance (e.g., heightened anxiety can impact performance on tests of perceptual speed).

The zone of proximal development (ZPD) developed by Lev Vygotsky (1896–1934) and Reuben Feuerstein’s theory of mediated learning experience (MLE) served as the primary foundations for most of the dynamic assessment approaches (Feuerstein, Rand, & Hoffman, 1979; Tzuriel, 1999). It is important to note that dynamic assessment is intended to supplement, not replace, standardized testing. It is a broad assessment approach, rather than a particular test. Some standardized test batteries have features of dynamic assessment (e.g., KABC-II contains

teaching items that can be used with examinees before the administration of sample items).

Disadvantages of dynamic assessment include: (1) the time and skill required to implement a dynamic assessment approach, (2) the extent to which cognitive modifiability can occur across all cognitive domains is largely unknown, and (3) the validation of DA is far more complex than validating static assessment approaches because dynamic assessment has broad goals (e.g., assess initial performance, assess cognitive functions, identify any deficit functions, determine the nature and amount of remediation needed to address the deficit, identify noncognitive factors and the role they play in cognitive performance, and identify the parameters or goals for future change). By allowing the examiner to administer a test instrument in a non-standardized way, the ability to replicate the test results is more limited due to the potentially inconsistent nature of test administration. Overall, to validate dynamic assessment approaches, one needs to develop criteria variables that measure changes that are directly relatable to any applied cognitive intervention.

Alternative, or Portfolio-Based Assessment. Another type of assessment is *alternative assessment*, or *portfolio-based assessment*. This type of assessment is often longitudinal and very idiosyncratic in nature, as teachers, students, and even parents at times, select pieces from a student's work over several years (four years, on average) to demonstrate what learning progress has occurred over the years. Alternative assessments encourage all relevant individuals (teachers, students, parents) to become active participants in the documentation of the learning process (Quinto & McKenna, 1977). Although the terms portfolio-assessment and performance assessment sound similar, the latter involves looking at actual student work produced over time and the processes by which the students produced such work, be it individually or collaboratively. In contrast, the former involves focusing on the products and processes of learning as well as other factors, such as the students' interest in learning, their concept of themselves as readers and/or writers, and their ability to evaluate their own work and set learning goals for themselves. Examples of portfolio- or performance-based assessment include such things as tape-recorded samples of students' oral reading, results of reading interviews focused on identifying students' understanding of the reading process (e.g., strategies they used to decode problem words or comprehend text), records of students' reading lists to gain information regarding reading interests, and so forth.

Overall, alternative assessment is derived from student's daily classroom work. Minimally, it involves collecting student work samples, recording observations of learning processes, and student and/or teacher evaluation

of students' processes and products. While such information can be summarized quantitatively for grading purposes, the primary goal of such assessment is to improve both teaching methods and students' learning.

Other Forms of Assessment and Testing. While static assessment approaches such as norm-referenced testing and criterion-referenced testing, curriculum-based assessment, and dynamic assessment approaches are used to varying extents in academic settings, other assessment techniques are also used, including interviews, anecdotal records, rating scales, classroom quizzes and tests, observation, and self-report techniques (Mercer, 1997; National Commission on Testing and Public Policy, 1990).

Each form of testing gathers information regarding a student or group of students and allows for a different type of interpretation and usage of data applied. Like the sides of a cut diamond, each shines in areas in which it is strong but is only a limited facet of the whole.

STANDARDS FOR EDUCATIONAL AND PSYCHOLOGICAL TESTING

The appropriate development and use of assessments are essential requirements for responsible professional practice in educational testing and measurement. The American Educational Research Association (AERA), the American Psychological Association (APA), and the National Council on Measurement in Education (NCME) have collaborated on the development of Standards for Educational and Psychological Testing (hereafter referred to as the Standards) since 1966. There have been four revisions to these joint standards since they were first issued as separate technical recommendations for achievement tests and psychological tests by AERA and NCME in 1955, and APA in 1954. A subsequent edition of the Standards was published in 1999, and another revision was scheduled to begin in 2008.

When the Standards were developed the test user was assumed to be a trained professional who generally had some graduate training and supervised experience in assessment. These *primary test users* would include test developers, testing contractors, state and district assessment directors, and school counselors who develop or use tests for decision making purposes (Camara, 1997).

In the early 2000s, the term *test user* encompasses a much broader group of *secondary test users*, including individuals with little or no training in measurement

and assessment such as teachers, parents, policymakers, and the media (Camara, 1997). Policymakers and educational administrators may have great influence over the use of assessment results and may misuse assessments in the 21st-century accountability environment (Berliner & Biddle, 1995). The further the test users are from the assessment, the less familiar they may be with the intended use of the assessment, evidence supporting the validity of inferences concerning the use of assessment results, and test content and characteristics of the test-taking population, which increases the likelihood of test misuse (Camara and Lane, 2006).

PURPOSE AND USE OF THE STANDARDS

The Standards have continued to emphasize that their primary purpose is to provide criteria for evaluating tests and testing practices and to encourage test developers, sponsors, publishers, and users to adopt the Standards, but there is no requirement on members of the professional associations or testing organizations and users to do so. They also note that the Standards do not attempt to provide psychometric answers to policy or legal questions. In 1999 the Standards abandoned the former designations of each standard as primary (required for all tests before operational use), secondary (desirable, but not required), or conditional (applicable in some instances and settings) (AERA et al., 1999). This change met with some criticism and controversy because it appeared to remove any absolute criteria or requirements for testing and test use and relied more on professional judgment in adherence to each standard.

The Standards also apply broadly to a wide range of standardized instruments and procedures which sample an individual's behavior that can include tests, assessments, inventories, and scales, for example. The main exceptions in applying the Standards are for unstandardized questionnaires (e.g., unstructured behavioral checklists or observational forms), teacher-made tests, and subjective decision processes (e.g., teacher evaluating classroom participation over the semester). The Standards apply equally to standardized multiple-choice tests as they do to performance assessments (including tests comprised only of open-ended essays) and hands-on assessments or simulations.

There is no mechanism to enforce compliance to the Standards on the part of the test developer or test user. As of 2008, many tests are sold and marketed that do not provide documentation required concerning their appropriate use, validation evidence to support such uses, and basic technical documentation such as the reliability of the score scale or a description of the normative or standard setting samples used for score reporting. Some

publishers have ignored requests for technical manuals or validation studies, citing the proprietary nature of their clients, while some test users have used tests for unintended and multiple purposes with no concern for collecting additional evidence to support such uses. Requests for proposals from states and local educational departments nearly always refer to the Standards and frequently include a broad statement to the effect that vendors responding to the RFP must comply with the Standards; yet few states have conducted detailed audits of their assessment programs in direct reference to all the applicable standards.

Wise (2006) describes how technical advisory committees (TACs) and the peer review process used by the U.S. Department of Education for assessment systems under No Child Left Behind (NCLB) are efforts to improve the quality of testing but do not base reviews on all relevant components of the Standards. Madaus, Lynch, and Lynch (2001) and Kortz (2006) have described the need for some independent mechanisms to interpret, encourage compliance with, or even enforce the Standards. However, the Standards have been referred to in law and cited in Supreme Court and other judicial decisions, lending additional authority to the document. For example, they have been cited in Goals 2000: Educate America Act¹ and Title I (Elementary and Secondary Education Act)². They were also cited in several major court decisions involving employment testing, including a Supreme Court case in 1988³.

ADDITIONAL STANDARDS AND GUIDELINES IN TESTING

The APA adopted the first formal ethics code for any profession using assessments in 1952. Eighteen of approximately 100 principles in that Code (APA, 1953) addressed issues such as qualifications of test users, security of testing materials, documentation required in test manuals, and responsibilities of test publishers and test users. Ethical standards for assessment are one of nine areas addressed by the current code (APA, 2002). Many other professional associations with members involved in assessment similarly adopted ethical standards and professional codes between the mid-1980s and 2005. Increased public awareness of ethical issues, the variety of proposed and actual use of assessments, and the increased visibility and importance placed on assessments for accountability have resulted in greater attention to ethical and professional responsibilities by many professional associations (Eyde & Quaintance, 1988; Schmeiser, 1992).

In the early 1990s the American Counseling Association (ACA) and AERA each approved ethical standards that cover a broad range of standards for behavior in counseling and educational research but make only passing reference to assessment. Ethical standards of ACA

(1998), APA, and the National Association of School Psychologists (NASP, 1997; 2000) are unique in that these associations support formal enforcement mechanisms that can result in suspension and expulsion of members, respectively (Camara, 1997)⁴. Ethical standards were first adopted by AERA in 1992 and revised twice thereafter. The standards as of 2008 (AERA, 1999) are designed to guide the work of educational researchers but are not enforceable.

In contrast to laws and regulations that are designed to protect the public from specific abuses, ethical standards and codes attempt to establish a higher normative standard for a broad range of professional activities and behaviors. For example, APA's Ethics Principles state: "if this Ethics Code establishes a higher standard of conduct than is required by law, psychologists must meet the higher ethical standards" (2002, p. 1062). ACA, AERA, APA and the Society for Industrial and Organizational Psychology (SIOP) have followed up the development of ethics codes with casebooks that attempt to guide users in interpreting and applying their standards.

The increased use of tests for accountability has also increased the urgency of informing and educating secondary users of their responsibilities in the appropriate and ethical use of tests and test data. In 2000 the U.S. Department of Education's Office of Civil Rights drafted a resource *Guide on High Stakes Testing* for educators and policy makers (2000) that attempted to interpret the technical and professional testing standards and legal principles and apply them to high stakes uses in schools, but as of 2008 the guide had not been disseminated following a change of administrations. Standards for Educational Accountability Systems (CRESST, 2002), which attempt to apply professional standards to accountability systems for a broad group of educators, were developed after passage of educational reform law.

The Code of Fair Testing Practices in Education (Joint Committee on Testing Practices, 2004) attempts to condense the most salient statements concerning the responsibilities of test users and test developers from existing codes and standards in four areas: (a) development and selection of tests; (b) administration and scoring of tests; (c) reporting and interpretation of test results; and (d) informing test takers. The Code has been endorsed by most of the major test publishers and is frequently reproduced on Web pages and publications in an attempt to guide educational professionals in appropriate practice and use of assessments. Most other technical and professional standards have a much more limited distribution, primarily to members, while the Code encourages reproduction and dissemination. A similar document, *Responsibilities of Users of Standardized Tests* (Association for Assessment in Counseling, 2003),

was developed to enhance ethical standards and assist counselors in the ethical practice of testing.

TEST DEVELOPMENT

Ethical and professional issues relating to the development of assessments is a broad area that includes test construction (the technical qualities of assessments, evidence supporting the validity of inferences made from test results, and norms and scales) as well as modifications to the test, technical documentation, statements and claims made about assessments, and appropriate use of copyright materials. Technical competence in the development and selection of assessments is an ethical issue. APA's Ethics Code states that persons who develop tests "use appropriate psychometric procedures and current scientific or professional knowledge for test design, standardization, validation, reduction or elimination of bias and recommendations for use" (2002, p. 1072). Test developers are responsible for ensuring that assessment products and services meet applicable professional and technical standards and should be familiar with the Standards and other applicable requirements. They also have a responsibility for providing technical documentation on their tests, including evidence of reliability and validity that supports inferences that will be made from test scores. Technical qualities for many educational tests also include construct representation and curriculum relevance (Messick, 1989). Educators who select among *off-the-shelf* tests should ensure that the content specifications of the tests align with the curriculum and that assessment formats are relevant. The Standards reiterate the importance of construct relevance as a central requirement in the validation argument (AERA et al., 1999).

Test developers need to employ appropriate processes for item development, review, and test assembly to ensure potentially offensive (or biased) content or language is avoided and test content is relevant for the intended use. Evidence that differences in performance across major subgroups are related to the construct being measured and not due to construct irrelevant variance is also a professional responsibility of developers (Joint Committee on Testing Practices, 2004). Test development also includes obtaining appropriate permissions when copyrighted texts or art work are used for an assessment. The Standards reiterate that tests should be developed on a sound scientific basis (AERA et al., 1999).

A number of potential dilemmas may arise for test developers who produce off-the-shelf, as well as those who purchase these tests. For example, a test contract may require a developer to produce many more items in a short period of time than the organization is capable of developing while meeting acceptable quality standards. The increased assessment demands from local, state, and

federal arenas may require test developers to take actions to meet scheduling and economic constraints that can threaten the technical quality of an assessment program. Sometimes the demand of test production may outstrip the resources of a test publisher and result in errors that may have been prevented with a more reasonable schedule (Phillips and Camara, 2006).

Test users who attempt to use a test for multiple purposes must provide evidence to support the use of the test for each proposed purpose unless existing evidence has been provided by the publisher or other sources. Educators often propose using the same test for both formative and summative purposes or to provide student, teacher, and school accountability functions as well as instructional, diagnostic, and placement purposes for the student. Evidence to support each specific use should be provided according to the Standards.

Rhoades and Madaus (2003) report on several instances in which insufficient piloting and pretesting led to spurious results, and time schedules for accountability tests did not allow for all the quality control procedures needed to detect and correct errors prior to test administration. In some situations, the desire to have tests drive the curriculum may conflict with any accountability uses for test results. For example, math teachers recruited to determine test specifications for a state accountability test may insist that a new eighth grade assessment require the use of graphing calculators to send a signal to students and all teachers about the need to introduce students to this technology and to compel the state to support the purchase of graphing calculators and appropriate professional development. However, if students are required to take the test before they are proficient in the use of graphing calculators, then the assessment is measuring construct irrelevant variance. Opportunity to learn is an important component of tests designed to measure achievement. In each of these instances, the technical quality of the assessment raises professional and even ethical issues that are more serious when the stakes associated with the testing program are higher.

The development of standardized administrative procedures and appropriately modified forms of tests and administrative procedures is also a responsibility of test developers (AERA et al., 1999; Joint Committee on Testing Practices, 2004; NCME, 1995). Modifications in test forms, response format, and test setting or content for students with disabling conditions or diverse linguistic backgrounds should be clearly described so that test users can reduce potential misuse of assessments.

Finally, technical documentation is a major requirement of any testing program. The first technical recommendations and standards produced by a professional association (APA, 1954) were largely developed to

address the concern that tests were often released without adequate supporting documentation and research (Novick, 1981). NCME's Code (1995) notes that current technical information to support the reliability, validity, scoring and reporting processes, and other relevant characteristics of the assessment should be made available to the appropriate persons. The *Code of Fair Testing Practices in Education* (2004) and Standards (AERA et al., 1999) add that technical information provided to users should also include the level of precision of test scores, descriptions of test content and skills assessed, and representative samples of test items, directions, answer sheets, and score reports.

The increased importance placed on the use and results of high stakes assessments has not only placed enormous pressure on students, teachers, principals, school boards, and other parties inside the educational system; it has created additional professional and ethical demands on measurement and testing professionals. The increased stakes associated with educational testing has led to a variety of unintended consequences that impact curriculum, teacher training, and professionalism in areas not directly tied to assessment as well as errors in the testing process itself (Cizek, 2001; Phillips and Camara, 2006). The Standards (AERA et al., 1999) and other professional, technical, and ethical guidelines that address assessment professionals provide guidance on many of the issues measurement professionals have long encountered in test development, test use, and test reporting.

NOTES

1. PL 103-227 Goals 2000: Educate America Act Sec. 211 Purpose States "the National Education Standards and Improvement Council shall. (5) certify State assessments submitted by States or groups of States on a voluntary basis, if such assessments (A) are aligned with and support State content standards certified by such Council; and (B) are valid, reliable, and consistent with relevant, nationally recognized, professional and technical standards for assessment when used for their intended purposes." The Federal Register, 43, pp. 38290-38315.) defines assessment under Goals 2000 act as, "ASSESSMENT Any method used to measure characteristics of people, programs, or objects. (American Educational Research Association, American Psychological Association, & National Council on Measurement in Education. [1985]. Standards for educational and psychological testing. Washington, DC: American Psychological Association.)"
2. Title I ESEA (Guidance on Standards, Assessments, and Accountability) "Title I requires that the assessment system be used for purposes that are valid and reliable and that it meet nationally recognized professional and technical standards. . . The primary reference for technical quality of educational assessments is *Standards for Educational and Psychological Testing* (1985), developed by the American Educational Research Association, the American Psychological Association, and the National Council on Measurement in Education." (see <http://www.ed.gov/policy/elsec/guid/standardsassessment/guidancepg4.html>).
3. *WATSON v. FORT WORTH BANK & TRUST*, 487 U.S. 977 (1988) 487 U.S. 977
4. The National Association for College Admission Counseling (NACAC) has developed standards of practice and other policy guidelines that are enforceable to its institutional members.

STANFORD-BINET INTELLIGENCE SCALES

The Stanford-Binet Intelligence Scales: Fifth Edition (SB-5; Roid, 2003a) is a test of intelligence/cognitive abilities for individuals 2 to over 85 years of age (child, adolescent, and adult). It is a major revision of the Stanford-Binet Intelligence Scales: Fourth Edition (SB-4; Thorndike, Hagen, & Sattler, 1986) and took seven years to complete. The complete SB-5 takes between 45 and 75 minutes to administer while the Abbreviated Battery takes between 15 and 20 minutes to complete. The Abbreviated Battery was included to allow for quick estimation of general intellectual abilities for screening purposes and includes the Nonverbal Fluid Reasoning and Verbal Knowledge subtests. These subtests are also used as routing subtests to provide estimates of intellectual functioning for placement into the appropriate level of test items better matching the individual's abilities. Use of the SB-5 may be for assessing mental retardation,

learning disabilities, developmental disabilities, and intellectual giftedness, although diagnosis of mental retardation also requires assessment of and significant deficits in adaptive behaviors. The SB-5 examiner's manual articulates test user qualifications, including college and/or graduate training in statistics and measurement for understanding test scores; thorough understanding of standardized administration, scoring, and calculation of standardized scores; and supervised training in administration via training workshops and/or graduate school testing courses.

HISTORICAL BACKGROUND AND DEVELOPMENT

The SB-5 evolved out of the original pioneering work of Alfred Binet (1857-1911), Victor Henri, and Théodore Simon in France during the late 1800s and early 1900s. Binet and Henri (1895) defined intelligence in terms of complex mental abilities (i.e., memory, abstraction, judgment, and reasoning) whereas Sir Francis Galton (1822-1911) had previously relied primarily on measuring physical and sensory abilities in assessing individual differences. Binet and Henri also developed tasks to measure these complex mental abilities. In 1904 the Minister of Public Instruction in Paris established a committee charged with finding a means to differentiate mentally retarded from normal children, and Binet was appointed to this committee. Earlier work by Binet and Henri and collaboration with Simon evolved into the first practical test of intellectual abilities for the diagnosis of mental retardation: the Binet-Simon Scale of Intelligence (Binet & Simon, 1905). Revisions and improvements of the Binet-Simon Scale of Intelligence were published in 1908 and 1911. Due to the success of the Binet-Simon Scale in France; Henry H. Goddard, Frederick Kuhlmann, J. E. Wallace Wallin, and Robert M. Yerkes each created translations of the Binet-Simon Scale of Intelligence for their use in the United States (Kaufman, 1990), but these different translations were not comparable and proved problematic. It was Lewis M. Termin who provided the most comprehensive translation and adaptation of the Binet-Simon Scale of Intelligence and provided better standardization. Termin's measure has survived to the present day through numerous revisions.

STANFORD BINET INTELLIGENCE SCALES FIFTH EDITION (SB 5)

The Stanford-Binet Intelligence Scales: Fifth Edition, (SB-5; Roid, 2003a), is a major revision and restructuring based on the hierarchical model of intelligence measurement illustrated by John B. Carroll (1993) and previous work by Raymond B. Cattell (1943, 1963) and John L. Horn (Cattell & Horn, 1978). The Cattell-Horn-Carroll

Factors	Domains	
	Nonverbal	Verbal
Fluid reasoning	Nonverbal fluid reasoning <i>Object series/matrices*</i>	Verbal fluid reasoning <i>Early reasoning (Levels 2–3)</i> <i>Verbal absurdities (Level 4)</i> <i>Verbal analogies (Levels 5–6)</i>
Knowledge	Nonverbal knowledge <i>Procedural knowledge (Levels 2–3)</i> <i>Picture absurdities (Levels 4–6)</i>	Verbal knowledge <i>Vocabulary*</i>
Quantitative reasoning	Nonverbal quantitative reasoning <i>Quantitative reasoning (Levels 2–6)</i>	Verbal quantitative reasoning <i>Quantitative reasoning (Levels 2–6)</i>
Visual-spatial processing	Nonverbal visual-spatial processing <i>Form board (Levels 1–2)</i> <i>Form patterns (Levels 3–6)</i>	Verbal visual-spatial processing <i>Position and direction (Levels 2–6)</i>
Working memory	Nonverbal working memory <i>Delayed response (Level 1)</i> <i>Block span (Levels 2–6)</i>	Verbal working memory <i>Memory for sentences (Levels 2–3)</i> <i>Last word (Levels 4–6)</i>

Note: *Routing subtests. Subtests presented in bold. Table adapted from Roid (2003b) Figure 2.1.

Table 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

(CHC) model of the structure of intellectual abilities is hierarchical with 50 to 60 narrow abilities at the bottom (Stratum I), 8 to 10 broad ability factors in the middle (Stratum II), and the general (g) ability factor at the top (Stratum III). The SB-5 activities and subtests measure a number of Stratum I dimensions, SB-5 Factors measure five Stratum II dimensions, and the Full Scale IQ measures Stratum III (g [general intelligence]). A number of subtests from the SB-4 were eliminated while new subtests were created and included in the SB-5.

The SB-5 (Roid, 2003a) includes ten subtests selected and designed to measure five CHC factors (fluid reasoning, knowledge, quantitative reasoning, visual-spatial processing, and working memory) within verbal and nonverbal domains. A global, Full Scale IQ score is provided in addition to Verbal IQ, Nonverbal IQ, and five composite factor scores. All scores are based on a mean of 100 and standard deviation of 15. Table 1 presents the SB-5 subtests (in bold) and the activities within subtests (in italics) used to measure the subtests specific to the different levels. Performance on the two routing subtests (nonverbal fluid reasoning and verbal knowledge) place individuals into the level appropriate for assessment. Recommendations for interpretation of SB-5 scores include the Full Scale IQ, comparisons of the Verbal and Nonverbal IQs, and the five factor scores (Roid, 2003b, 2003c).

Full Scale IQ scores range from 40 to 190, covering a wide range of intellectual abilities (± 4 SDs). This allows for assessment to the lower levels of moderate

mental retardation to the higher levels of intellectual giftedness. Verbal IQs range from 43 to 156 and Nonverbal IQs range from 42 to 158, providing a wide range. Factor scores also have wide ranges of possible scores (fluid reasoning: 47 153, knowledge: 49 151, quantitative reasoning: 50 149, visual spatial processing: 48 152, working memory: 48 152).

The standardization sample of the SB-5 was stratified to closely match the 1998 United States Census data on key demographic variables of geographic region, race/ethnicity, age, and socioeconomic level for generalizing performance to the population. Socioeconomic level was estimated by the number of years of education completed or in the case of children, their parent's education level. Other technical characteristics, such as reliability (internal consistency, stability, and interrater agreement) and validity of SB-5 scores were generally considered positive in two independent reviews (Johnson & D'Amato, 2005; Kush, 2005). Both reviews noted improvements over the SB-4 but both also noted some problems.

INDEPENDENT RESEARCH WITH STANFORD BINET INTELLIGENCE SCALES FIFTH EDITION

Gale H. Roid (2003a, 2003b, 2003c) claimed the Stanford-Binet Intelligence Scales-Fifth Edition (SB-5) measured five CHC intelligence factors within verbal and nonverbal domains based on the test design and on use of confirmatory factor analysis (CFA) procedures. Factor analysis includes several approaches to investigate

how a variety of measures relate and thus, how they define underlying dimensions. Generally, CFA procedures examine competing structural models to see which fits the data best while exploratory factor analysis (EFA) examines a correlation matrix to determine how many factors or dimensions should be extracted and retained to reflect the underlying structure.

Independent studies have seriously challenged the claim that the SB-5 measures five-factors using SB-5 standardization data. Christine DiStefano and Stefan C. Dombrowski (2006) recognized the problem of not using, or reporting, EFA and set to rectify this in their study of the SB-5 standardization data. They used both EFA and CFA procedures to determine the underlying structure of the SB-5. None of the analyses (EFA or CFA) performed by DiStefano and Dombrowski on the SB-5 standardization sample data found evidence for a five-factor model and only modest support was found for two-factors (verbal and nonverbal) and only with the two youngest age groups. The verbal and nonverbal dimensions were so moderately (EFA) to highly (CFA) correlated, DiStefano and Dombrowski concluded that the SB-5 was probably best explained as a unidimensional test of intelligence.

Gary L. Canivez (2007a, 2007b), like DiStefano and Dombrowski (2006), also failed to find empirical evidence for a five-factor model and further investigated the viability of the two-factor (verbal & nonverbal) SB-5 model for the child and adolescent subsamples from the SB-5 standardization sample. Using a hierarchical exploratory factor analysis method (Schmid & Leiman, 1957), which is a recommended procedure to understand how variance is apportioned at different interpretive levels (Carroll, 1993; Carretta & Ree, 2001), Canivez (2007a, 2007b) found that the overwhelming majority of variance measured by the SB-5 was at the general intelligence factor level (Carroll's Stratum III) and little variance seems to be measured at the lower level (verbal and nonverbal, Carroll's Stratum II). Failure to find support for Roid's (2003c) five factors and limited support for even two factors (Canivez, 2007a, 2007b; DiStefano & Dombrowski, 2006) may be the result of Roid extracting too many factors due to not considering exploratory factor analyses and multiple factor extraction criteria (Frazier & Youngstrom, 2007). As a result, clinical interpretation of the SB-5 should primarily reside at the global, general intelligence level until research adequately supports interpretation of lower-order (Stratum II) dimensions.

In summary, the SB-5 appears to be a very good measure of general intelligence across a wide age range, and the standardization sample appears to be a close match to the population on key demographic variables.

IQ scores also cover a wide range of ability from the lower levels of moderate mental retardation to the higher levels of intellectual giftedness. As such, they will be helpful in assessing students with mental retardation, learning disabilities, and intellectual giftedness, and interpretation of the global Full Scale IQ appears to have strong empirical support. However, as of 2007 much more research is required before interpretation of two- or five-factor models can be supported or recommended.

Gary L. Canivez

STEREOTYPE THREAT

According to Steele and Aronson (1995), stereotype threat is defined as a “socially premised psychological threat that arises when one is in a situation or doing something for which a negative stereotype about one’s group applies” (Steele, 1997, p. 614). Another description of stereotype threat suggests that individuals are at risk of confirming a negative stereotype about their group. Here, individuals who experience stereotype threat are 1) acknowledging that a negative stereotype exists (i.e., salient in a given context or is explicitly stated) about the capabilities of their social group (i.e., race/ethnicity, gender, age, socioeconomic status) and 2) demonstrating apprehension about confirming the negative stereotype by engaging in particular activities.

An example of stereotype threat is a member of a stigmatized group (i.e., African American students, women) feeling apprehension about performing on an academic task because the individual is afraid that a possible poor performance may confirm a pre-existing negative stereotype about the individual’s group (i.e., intellectual capabilities of African Americans or perceived underperformance of women in science and mathematics). For Steele, it is unnecessary for the group member to believe the stereotype to be true for stereotype threat to produce negative psychological consequences for the individual. That is, the psychological reactions to stereotype threat—exposure to contexts in which negative stereotypes about the capabilities and behaviors of a given group are or have been salient—are enough to alter

the attitudes and behaviors of individual group members and produce maladaptive psychological functioning.

TASK PERFORMANCE SUBVERSION

Much of the research on stereotype threat has shown that the task performance of otherwise capable individuals is hindered when such a social-psychological threat is presented at the time of the performance (Aronson et al., 1999; Steele & Aronson, 1995; Steele, 1997). Steele (1997) and Aronson (2002) write that, for many stigmatized groups—namely women and ethnic minority populations—stereotype threat is a common reality. In particular, low-income African American and Latino students are often exposed to academic contexts in which, historically, negative beliefs regarding their perceived intelligence have been held. The awareness and salience of the belief regarding their intelligence can disrupt academic performance for these students.

The consequences of stereotype threat have been noted. For example, in a review, Aronson (2002) notes that perceptions of negative stereotypes lead many individuals to engage in activities such as self-handicapping (Smith, 2004), challenge avoidance (Good, Aronson, & Inzlicht, 2003), self-suppression (Steele, 1997; Pronin, Steele, & Ross, 2002), and disidentification or disengagement with the task or the context in which the task is to be performed (Steele, 1997; Aronson, 2002; Major et al., 1998). In addition to these poor academic performance correlates, stereotype threat has also been linked to high blood pressure among African Americans (Blascovich et al., 2001), altered career and/or professional aspirations and belonging (Steele, James, & Barnett, 2002), and social distancing, particularly from the stigmatized social group of which the participants are members (Pronin, Steele, & Ross, 2002).

These psychological and behavioral outcomes found among low-income African American and Latino and women students are not typically the result of negative stereotypes being communicated directly to them from others within the given social context. Rather, these behaviors typically result from exposure to a context in which historically 1) the performance of a given group is evaluated and compared with that of others, 2) such performance has been valued by the group and the larger society, and 3) the performance of one’s group has been consistently negatively evaluated and thus stereotyped more than other groups.

MAJOR FINDINGS ON STEREOTYPE THREAT IN ACADEMIC DOMAINS

Much of the support for the presence and effects of stereotype threat has been garnered through experimentally designed studies that have been based on the

research of Claude Steele and Joshua Aronson (Steele & Aronson, 1995; Steele, 1997). In each study, participants were primed toward greater awareness of a negative stereotype either about their group or a group believed to be superior to their group. The psychological effects of this priming were the major dependent variables of interest across their works.

For example, Steele and Aronson (1995) first tested the effects and corollaries of stereotype threat with African American college students. In the first of four experimentally designed studies, Steele and Aronson (1995) gave a 30-minute GRE verbal exam to 114 undergraduates. Using a 2 (race) x 3 (threat condition) factorial design, Steele and Aronson (1995) created and analyzed the effects of race (African American and White) and testing condition on students' performance on the graduate records exam (GRE). Similar to the research on stereotype threat and women's math performance, Steele and Aronson (1995) noted that African American and White students were matched on verbal ability prior to being recruited for participation in the study.

In the first testing condition, African American and White students were exposed to the stereotype threat condition in which the GRE exam was described by the researchers as a test to determine diagnostic ability on verbal competence. The second condition, non-stereotype threat, consisted of communication by the researchers that the students' test taking and performance were not diagnostic of ability and was only considered to be a routine laboratory task. Finally, the third condition consisted of communication by researchers indicating that the non-diagnostic task should be considered a challenge, but not indicative of their fixed intelligence. Results from the first study indicated that, after controlling for differences in SAT scores, African American students in the diagnostic (stereotype threat) condition fared worse on the GRE verbal examination than their White counterparts in the same condition and also African American students in the non-diagnostic and challenge conditions.

In study two, 40 undergraduates were recruited to participate in the study in which the same experimental conditions and procedures were employed. Here, a significant interaction emerged, with African American students in the diagnostic (stereotype threat) condition performing significantly worse than all other students in the remaining experimental conditions. Also noted were the findings that African American students in the stereotype threat condition yielded lower response accuracy and had more incomplete responses than their African American counterparts in the non-diagnostic condition. White students in both conditions also had higher response accuracy than African American students in the diagnostic, stereotype threat condition.

In addition to research with African American students, Steele and colleagues also carried out research on stereotype threat with another stigmatized group: women. Throughout these studies, stereotype threat was operationalized by stating a phrase that would evoke knowledge of and reactions to negative stereotypical beliefs about a particular group's ability on an academically premised experimental task. For example, Spencer, Steele, and Quinn (1999) tested the belief that women generally perform less well on standardized mathematics examinations as a result of stereotype threat. The study sample included undergraduate males and females deemed equally competent in mathematics performance. The criteria for such included completion of one semester in calculus with a grade of B and a score above the 85th percentile on the math subsection of the Scholastic Aptitude Test or American College Test (Steele, 1997).

To operationalize stereotype threat for the participants, students were told that the test had shown gender performance differences in the past. This would "explicitly evoke the stereotype about women's math ability" (p.11). In the other condition, students were told that the math examination did not yield gender performance differences. In this study, women in the stereotype threat condition were outperformed by men in the same condition, even though students from both gender groups had equitable ability and exposure to mathematics. In the non-stereotype condition, women performed equally to the men. A significant interaction between gender and test condition (gender difference/stereotype threat and no gender difference/non-stereotype threat) found that women in the stereotype threat condition scored the lowest on the math exam whereas no other significant differences among the four conditions emerged.

While much research on stereotype threat has shown that many persons from low-income and ethnic minority and gender minority statuses can experience the psychological threat of negative stereotypes, research has also shown that virtually any member of any group can experience stereotype threat (Aronson, 2002; Smith, 2004; Steele, 1997). For example, some research has shown negative or maladaptive effects of stereotype threat on a variety of groups, including the elderly (Levy, 1996), White males (Aronson et al., 1999), elementary and middle grade school students (Ambady et al., 2001), and low-income French and American students (Croizet & Claire, 1998; Spencer & Castano, 2007). In one study, elderly participants performed significantly worse on a short-term memory task when they were exposed to negative stereotypes regarding societal perceptions of old age and senility than their counterparts who did not receive such messages (Levy, 1996). Another study showed that White male mathematics majors could fall victim to stereotype threat,

even though this population is typically not viewed as being stigmatized or marginalized.

In particular, Aronson and colleagues (1999) had White male undergraduate mathematics majors complete math tasks in one of two conditions: a stereotype threat condition and a non-stereotype threat condition. The stereotype threat prompt that they read suggested that they were participating in a study designed to determine why Asians seem to perform better on math examinations. Findings from this study showed that White male math majors in the stereotype threat condition performed significantly less well than their counterparts in the non-stereotype threat condition.

WAYS TEACHERS CAN STRUCTURE CLASSROOMS TO REDUCE STEREOTYPE THREAT

These studies and others by Steele and his colleagues have affirmed the idea that many students, but particularly low-income African American and female students, face added stressors in testing situations. These psychological stressors have little to do with students' sense of competence regarding intellectual tasks, but rather they stem from the societal-premised, negative stereotypes associated with African Americans' performance in testing situations. Given these findings, Steele (1997) and Aronson (2002) have noted that the challenge for minimizing the effects of stereotype threat often relies in the ability of educators to successfully counter societal-premised group stereotypes.

One solution, proposed formally by Steele, is the creation of "wise schooling." Through wise schooling, Steele and others have sought to replace the intangible, yet omnipresent stereotype of academic difficulty and cognitive and intellectual inferiority with instructor-based behaviors and activities that express the idea that such stigmatized students can and are fully expected to fare well in general and successfully meet the high academic standard found in and across various academic domains and settings (Cohen, Steele, & Ross, 1999). In addition, wise schooling for Steele and colleagues duly includes communicating to and believing that the stigmatized students are capable of achieving high standards and expectations.

Some research has empirically supported the use of wise schooling to reduce the effects of stereotype threat. Using experimental methods, Cohen, Steele, and Ross (1999) studied White and African American college students, all of whom were matched on language arts/writing ability. These individuals were given an essay assignment to complete under one of three feedback conditions, each of which was characterized by written feedback to the students' essays to indicate condition. The first condition, unbuffered criticism, was believed to be typical of the

college performance evaluation experience. Here, feedback was largely directive and provided in a neutral, disaffected voice/manner that did not consider the emotional impact such an evaluation may have on students. A sample statement from the unbuffered criticism letter to students in this condition is as follows: "Your letter needs work in several areas before it can be considered for publication" (1999, p. 1306).

Another condition was the wise criticism condition, which included language that communicated high and tangible achievement standards. The first line of the wise criticism letter to students in this condition stated: "It's obvious to me that you've taken your task seriously and I'm going to do likewise by giving you some straight forward, honest feedback." Additional wording in the feedback letter stated: "I wouldn't go to the trouble of giving you this feedback if I didn't think, based on what I've read in your letter/essay, that you are capable of meeting the higher standard" (p. 1307). Finally, in the positive buffer condition, the same feedback was present as that in the wise criticism condition. However, the feedback was preceded by a paragraph that offered the student some praise for the work, prior to the revisions it needed. A sample sentence there was: "Overall, nice job" (p. 1307).

The independent variables in the study were student race and criticism condition whereas the dependent variables included task motivation and perception of teacher/instructor bias. The authors found that African American students in the unbuffered criticism condition were significantly lower in their task motivation and significantly higher in their reports of perceived instructor bias than White students in the same condition. The researchers state that the difference in task motivation and bias perception between White and African American students was virtually removed in the wise criticism and positive buffer conditions.

In addition to wise schooling techniques to reduce stereotype threat effects, Aronson (2002) identified several ways in which teachers can work to minimize stereotype threat in the elementary and secondary classrooms. Teachers should reframe how standardized tests, evaluations, and even grades are presented to students. This can be done by shifting the emphasis of assessment from a measure of ability to what Aronson refers to as a non-evaluative task. For example, a teacher can suggest to students that a test is actually examining how well the teacher has instructed the students rather than how well the students have learned and retained the material. Teachers can reduce stereotype threat by dispelling the idea that ability, skill, and intelligence are static characteristics. For Aronson, communicating to students that their skills and intelligence can be further developed and are, therefore, malleable rather than unalterable or fixed

can minimize the threat of stereotypes. Additional research has shown that teachers can deemphasize stereotype threat by emphasizing self-affirmation among the students and providing same-sex, same-gender role models to students in the classroom prior to their participation on an academic task (Cohen et al. 2006; McIntyre, Paulson, & Lord, 2003).

STERNBERG, ROBERT J (EFFREY)

1949-

Robert Jeffrey Sternberg was born on December 8, 1949, in Newark, New Jersey. He received his B.A. in psychology from Yale University in 1972, under the mentorship of Endel Tulving; and his Ph.D. in psychology from Stanford University in 1975, where he worked with Gordon Bower. After completion of his dissertation, Sternberg began his professional career at Yale University, where he remained for 30 years. Sternberg's career at Yale was extremely productive and resulted in the publication of more than 1,200 scientific and popular works and the establishment of the Center for the Psychology of Abilities, Competencies, and Expertise (PACE Center) in

Robert J. Sternberg, March 1, 2005. AP IMAGES.

2000. In 2005 Sternberg and the PACE Center relocated to Tufts University, where Sternberg accepted the positions of dean of the School of Arts and Sciences and professor of psychology.

Sternberg held many elected offices in professional organizations, including president of the American Psychological Association. He led as editor two major professional journals of the American Psychological Association, and served as associate editor, consulting editor, or member of the editorial board of more than 30 other psychological and educational journals. Sternberg's work has been recognized by honorary doctoral degrees from eight universities throughout the world and by 25 scholarly prizes and awards.

Sternberg has collaborated and published with a number of distinguished scientists, both senior (Endel Tulving and Gordon Bower) and peer (e.g., Douglas Detterman, Paul Ackerman and Howard Gardner). He also has a remarkable track record of publishing with his numerous current and former students, enhancing, stimulating, and promoting their careers.

The research of Robert Sternberg is extremely diverse, spanning the fields of cognitive, educational, personality, abnormal, and organizational psychology. In educational psychology, the main focus of his research has been the implications for teachers and students of individual differences in cognition and learning. For educators, the two most important theories are the theory of successful intelligence (also known as the triarchic theory of intelligence) and the theory of mental self government (also known as the theory of thinking styles).

The theory of successful intelligence defines intelligence as the ability of individuals to succeed in life by capitalizing on their strengths and compensating for their weaknesses.

According to Sternberg, abilities cannot be reduced to a single general measure of intelligence but should be developed and assessed in a multi-faceted manner. He defines three fundamental cognitive abilities; hence the original name triarchic theory of intelligence. Analytical abilities are needed for analyzing, evaluating, judging, comparing, and contrasting. Creative abilities are called for when there is a need to generate new knowledge. Practical abilities are required for the application and use of knowledge. The psychological building blocks of these abilities are the same, but individuals may demonstrate both integrated and uneven profiles across these dimensions. The theory of successful intelligence has been the subject of a wide range of studies. These range from the development and validation of the theory (see, for example, Sternberg, 1980) to application of the theory to college admission policies (e.g., Sternberg et al., 2006).

The theory of mental self-government postulates the presence of styles of thinking (or mental government) that form psychological bridges between individuals' intelligence and personalities. Sternberg differentiates 13 different styles of thinking. The primary types of styles are legislative, judicial, and executive, matching the three major functions of government. There are also four forms of styles (anarchic, oligarchic, monarchic, and hierarchic); two levels (liberal and conservative); two focuses (extra- and intro) and two dimensions (local and global). His empirical work validates the importance of recognizing the existence of different styles of thinking among both teachers and students to maximize the effectiveness of teaching and learning.

At the later stages of his career, Sternberg became interested in wisdom and developed an all-encompassing framework that embraces various components of his work; this framework is referred to as Wisdom, Intelligence, and Creativity Synthesized (WISC).

Sternberg's work has penetrated and influenced the field of education at all levels—research, practice and policy. His prolific writing has generated widespread attention and all contemporary textbooks in psychology and education mention his theoretical and empirical research.

STRATEGIES INSTRUCTION

A strategy is a plan of action for achieving a purpose (Harvey & Goudvis, 2007). With respect to classroom learning, purposes for employing strategies include the need to comprehend, compose, problem solve, remember, reason, evaluate, and decode. Students who have been taught strategies for accomplishing these purposes

have a distinct advantage over the uninstructed (Pressley, Graham, & Harris, 2006; Torgesen, 2004). Yet, researchers have found that most teachers do not teach the strategies students need to comprehend and learn (Durkin, 1978–1979; Pressley, Wharton-McDonald, Mistretta, & Echevarria, 1998). Neglecting to teach strategies for accomplishing classroom tasks is a serious oversight, especially when people realize that the learners who are most successful are also the ones who are able to, and do, employ many strategies (Bransford, Brown, & Cocking, 2000; Trabasso & Bouchard, 2002). Strategies put students in control of their mental processes (Duffy, 2002); thus, it would be in students' best interest if teachers in all areas of the curriculum taught strategies.

Appropriate strategies for accomplishing learning tasks vary depending on the desired outcomes and structure of the domain. In the domains of history, mathematics, and science, Donovan and Bransford (2005) note that students benefit from strategies which enable them to access and evaluate their preconceptions, develop a deep foundation of factual knowledge, understand facts and ideas in the context of a conceptual framework, and organize knowledge in ways that facilitate retrieval and application. In conducting science investigations, strategies include generating a research question, designing a study, and explaining the results. In literature, strategies for detecting theme, analyzing character traits, and recognizing different genres are important (Gaskins, 2005; Harmon, Martinez, & Deckard, 2004). Common to the domains of history, mathematics, science, and literature are the basic skills of reading and writing. In these two areas researchers suggest that students be taught strategies for decoding and encoding words, as well as for comprehending and composing. Research-based comprehension strategies include accessing background knowledge, predicting, self-questioning, constructing mental images, and summarizing (Pressley, 2006). In writing, a meta-analysis suggests that students need to learn strategies for planning, drafting, reflecting, and revising (Graham, 2006). In all areas of the curriculum, researchers recommend that students be taught strategies for taking control of their thinking (Donovan & Bransford, 2005; Schunk & Zimmerman, 1997).

This entry on strategy instruction is divided into three sections: (1) major approaches to strategies instruction, (2) characteristics of explicit, teacher-led strategies instruction, and (3) effective instructional supports for strategies instruction.

MAJOR APPROACHES TO STRATEGIES INSTRUCTION

There is little debate in the 21st century about the benefits to be gained from teaching students strategies

that will allow them to read, write, and learn independently (Deshler, Palincsar, Biancarosa, & Nair, 2007). The debate, with respect to strategies instruction, centers on which instructional approaches and contexts work best for which students and whose responsibility it is to teach strategies. This question is particularly relevant for students in grades 4 through 12, when the density of texts and concepts dramatically increase, and for students in all grades who have learning and reading difficulties (Alexander & Winne, 2006). There are at least three broad categories into which approaches to strategies instruction can be divided: (1) stand alone, in which strategies, heuristics, and/or study skills are taught as a separate course, usually with texts that are not part of the mainstream curriculum; (2) teachable moment, in which strategies are taught as students demonstrate a need for them; and (3) explicit, teacher-led instruction, in which teachers explain, model, scaffold, and guide practice regarding strategies that will be of immediate use in the completion of specific learning tasks that are part of the mainstream curriculum.

Different approaches may be beneficial for different people, depending on their backgrounds of knowledge in a domain, their learning strengths and challenges, and the context for learning. For students who read and write at levels significantly below their grade-level placement, particularly students who lack basic decoding and encoding strategies, stand-alone courses are sometimes needed as a supplement to the mainstream curriculum. For students with strong backgrounds in a domain, teachable-moment approaches may better meet their needs. Explicit, teacher-led instruction is the approach documented to be successful with students who demonstrate learning problems (Deshler, et al., 2007; Pressley & Harris, 2006; Swanson, 1999). There are also possible combinations and variations of the three main approaches described below.

Stand-alone Approach. In stand-alone approaches, strategies are taught outside the authentic situation in which they are expected to be applied. For example, students participating in a study skills course may be explicitly taught strategies for identifying main ideas, taking notes, and studying for tests, followed by teacher-directed, scaffolded practice in content-area materials. Often, however, the practice materials are not the same as those the students use in their content-area classes. For students who are motivated to learn these strategies and who also are aware of the appropriate occasions to apply them, a stand-alone course can be beneficial. The chances for application are increased if the students' regular classroom teachers are aware of the strategies that have been taught in the study skills course and can cue students when it is appropriate to use those strategies. The likelihood of transfer to authentic classroom situations is less

likely, unfortunately, for struggling students who most need to apply these strategies (Pressley & Harris, 2006).

Teachable-moment Approach. Those who favor the teachable-moment approach assert that teachers should wait until a student encounters a problem in completing a task or asks for clarification, and then coach the student in his or her application of appropriate strategies. A classic debate regarding teachable-moment interventions has for decades surrounded the teaching of strategies for decoding. There are those who believe that decoding strategies should not be explicitly taught, but rather students should be taught to problem solve when they encounter an unknown word. For example, when a student encounters the unknown word “turtle,” the teacher might ask: “What would make sense in the sentence and begins with *t*-?” If this clue is not helpful, the teacher might continue, “Do the pictures give you any clues that you could combine with the sense of the sentence and the sound for the first letter?” The goal of the teacher’s questioning is to model questions students might ask themselves when they encounter an unknown word.

Similarly, when students are stuck solving a math problem or understanding a science experiment, the teacher might mediate the application of the needed strategy by asking questions the students could ask themselves on another occasion when they are perplexed. Two possible concerns about using this approach are that it relies on teachers being skillful in asking mediating questions (rather than telling too much) and on teachers having a deep understanding of the developmental sequence of strategies that would be beneficial for students to employ in completing classroom learning tasks. Another consideration is that the teachable-moment approach can be labor intensive; thus it may work best in small classes and one-on-one tutoring.

Explicit Teacher-led Approach. The approach to strategies instruction most frequently supported by research, especially for children with learning problems, is the approach that features explicit teacher explanations of the what, why, when, and how of using strategies, accompanied by teacher modeling, scaffolding, and guided practice (Lipson, 2007; Gaskins, 2005). As noted earlier, explicit explanation of strategies is not practiced in most classrooms; however, two such programs that have received empirical support are Project CRISS (Santa, Havens, & Valdes, 2005) and Transactional Strategies Instruction (Pressley, El-Dinary, Gaskins, Schuder, Bergman, et al., 1992). These are examples of programs in which direct and explicit instruction in the reading, writing, and thinking strategies needed for success in content-area courses are taught as essential parts of the courses. Both programs emphasize professional develop-

ment. In part, explicit teacher-led approaches are not commonplace in classrooms because they are dependent on excellent pre-service and in-service professional development. The explicit approach has also been found to be difficult for teachers to put into practice (Hilden & Pressley, 2007). Explicit teacher-led instruction is discussed in greater detail in the next section.

CHARACTERISTICS OF EXPLICIT, TEACHER LED STRATEGIES INSTRUCTION

Research regarding reading comprehension in all areas of the curriculum strongly suggests that effective strategies instruction includes explicit explanations, modeling, scaffolding, and practice (Duffy, 2002; Pressley, 2006). Teachers of effective strategies instruction explicitly explain to students (1) what the strategy is that can be used to accomplish a specific task, (2) why and how the strategy facilitates learning, and (3) how and when to use the strategy (Gaskins, 2005). In addition, as recommended by Dimino (2007) and others, teachers use think-alouds (Meichenbaum & Biemiller, 1998) or mental modeling (Duffy, Roehler, & Herrmann, 1988) to share their thinking as they demonstrate using the strategy in authentic situations.

Thinking aloud, as described by Meichenbaum and Biemiller (1998), is verbally guiding oneself while carrying out a task. Teachers’ think-alouds may be in the form of self-questioning or directive self-instructional statements sharing with students what they think before, during, and after completing a task. In contrast, the goal of mental modeling, as discussed by Duffy, Roehler, and Herrmann (1988), is to make reasoning visible. Mental modeling is differentiated from the “modeling of procedures which consist of telling students directions or steps to follow in completing a specific task” (Duffy, et al., p. 765). Instead, in mental modeling, the focus is on the thinking one does to complete the steps, not on the steps themselves. The intent is to convey the flexibility associated with reasoning as opposed to rigid following of steps. Mental modeling is implemented “in tandem with fluid teacher-student dialogues to ensure that students do not misinterpret the modeling and end up with misconceptions” (p. 766).

As part of explicit strategies instruction, teachers also guide, support, and cue students as they gradually release responsibility to students for putting a strategy, or a bundle of strategies, to work. The teacher scaffolds (supports) students in the application of strategies during guided practice, turning as much responsibility over to each student as that student can successfully handle, with the goal being that each student achieves independence in strategy use at his or her own pace.

EFFECTIVE INSTRUCTIONAL SUPPORTS FOR STRATEGIES INSTRUCTION

The success of strategies instruction depends on more than explicit explanations, modeling, scaffolding, and gradual release of responsibility. Other instructional supports need to be incorporated into strategies instruction, if the use of strategies is to become habitual for students. These supports include: emphasizing metacognition; making strategies use meaningful by sharing learning principles and brain-related rationale; teaching strategies school-wide and across the curriculum; and providing opportunities for professional development. Each of these instructional supports is discussed below.

Emphasizing Metacognition. Dimino (2007) postulates that one essential component of an instructional design for effective and explicit instruction of strategies is metacognition, a concept introduced in the 1970s but as of the early 2000s still not commonly discussed in classrooms. Metacognition is composed of two parts: (1) knowledge about thinking and (2) self-regulation of thinking. Knowledge of thinking includes knowledge of high-utility strategies that enhance thinking, as well as how and when to employ them. It is also the knowledge gained from self-evaluation regarding which strategies are personally effective and work well in which situations. As part of developing student awareness, teachers encourage students to share strategies that have led to successful learning and problem solving, and they praise students for their effort in applying appropriate strategies. They also engage students in self-assessing their work and in attributing satisfactory attainment of academic goals to strategy use. The second aspect of metacognition is executive function or volition, taking control of thinking by self-monitoring and putting into action a plan to successfully meet a goal. Awareness alone does not produce success.

As strategies are practiced, teachers gradually transfer control of implementing the strategies to students. Students assume responsibility for knowing where and when to use the strategies and for independently using them. Thus, they become self-regulated (Schunk & Zimmerman, 1997). This ownership is possible because students have gained awareness and control of their thinking. Students who have been engaged in a systematic strategies program have been taught how to monitor progress toward a goal (e.g., solving a math problem, composing a science report, decoding a word, or understanding a text) (Gaskins, 2005). They know how to manage accomplishing their goals by such tactics as adapting strategies to their purposes, engaging in an inner conversation so they can catch themselves when they need to mend understanding, and matching the appropriate strategy to the situation so they can make renewed progress toward their goals.

Making Strategies Use Meaningful. Explicitly teaching strategies and adding all the components outlined above may still not be enough to develop self-regulated students who independently employ strategies. Instructional experts and researchers recommend including a motivational component to strategies instruction that focuses on meaningfulness, including interest and value (Alexander, 2006; Anderman & Wolters, 2006; Gaskins, 2008). Because learning and applying strategies initially takes quite a lot of effort, students want to see some value in putting forth the extra work. They often need to be convinced of how what they are asked to do will benefit them. This calls for personal or situational interest.

Students are more likely to be interested in and take strategies instruction seriously if teachers provide a convincing rationale for each strategy they teach (Paris, Lipson, & Wixson, 1983). For example, teaching students how strategies help the brain work more effectively has proved a convincing rationale (Gaskins, 1991, 2005, 2008). Perhaps this is the case because students enjoy hearing interesting stories and sophisticated information about learning theory and knowledge about how the brain functions that is usually reserved for college courses. Teachers share both why they are teaching a particular strategy and how the strategy helps the brain work more effectively.

For example, in teaching students to survey, the teacher's explanation of why might sound something like this: "We survey to hook our interest and to get a sense of what the text is about. In addition, the information you gain while surveying provides an outline that you can fill in with new information as you read" (Gaskins, 2005, p. 197). The teacher's explanation of how surveying helps the brain might sound like this: "Surveying helps your brain by telling it what background knowledge to get ready to assist you in understanding the new information" (p. 197). Similarly, in teaching students to access background knowledge, the teacher might say: "We access background knowledge to help us become actively involved by relating what we are reading to what we know" (p. 197). An explanation of how might include that accessing background knowledge helps the brain make sense of and remember what is read "because our brains don't remember things that don't make sense. We also want to hook new information to what we already know, because it is easier to get information back out of our brain if it is hooked to what we already know" (p. 197).

In the same vein, teachers explain how learning works by sharing principles of learning with students (Gaskins, 2008). Examples of principles that might be shared with students include: organized knowledge is easier to recall than random information; information that is thoughtfully and deeply processed is likely to be understood and used; and concepts and strategies that are repeatedly practiced and applied are not easily forgotten

(Gaskins, 2008). To make these principles even more convincing, teachers can conduct mini-experiments with students to illustrate the principles (Gaskins, 1991).

Teaching Strategies School-wide and Across the Curriculum. Strategies instruction and application must take place in authentic settings across the entire school (Allington, 2006). Effective teachers make strategies instruction an integral part of all classroom instruction all year long in all areas of the curriculum. Each year they teach a small repertoire of strategies, bundling a newly taught strategy with those that have been previously learned. For example, a teacher might initially teach beginning readers to survey a pre-primer story. After students have practiced surveying until they are comfortable with the strategy, the teacher then bundles surveying with accessing background knowledge by explicitly explaining and modeling how to access background knowledge related to the information gained from surveying. This lesson is ideally followed by teaching students to make predictions based on information gained from surveying and accessing background knowledge. For each strategy taught and bundled with other strategies, teachers explicitly explain, model, scaffold, and guide practice, and they guide students to apply or adapt strategies to all areas of the curriculum.

The goal of strategies instruction is that the application of strategies to comprehend, compose, problem solve, remember, reason, evaluate, and decode is self-regulated by students. This occurs when students receive explicit strategies instruction as described above throughout at least their elementary and middle school years, and they are guided in their application of high-utility strategies to authentic situations until strategies use is each student's chosen way of addressing learning, thinking, and problem-solving tasks in all areas of the curriculum..

Ideally, there is a school-wide or district-wide plan for strategies instruction in order to provide continuity and consistency of strategy instruction across the curriculum and across grades. With such a plan, each teacher knows what his or her responsibility is for introducing and reinforcing specific strategies, and students are much more likely to be strategic in their learning, thinking, and problem solving because strategies introduced during one school year are reinforced, expanded, and bundled with other strategies in each consecutive year of schooling (Pressley, 2006).

Providing Opportunities for Professional Development. Given that what is known about strategies teaching is underused in the late 2000s, it is imperative that there be ongoing professional development so that students have the benefit of instruction from teachers who know what works and how to implement instruction based on evidence from scientific investigations (Pressley, Graham, & Harris,

2006). In addition, because experience and research have indicated that teaching strategies has initially proved difficult for teachers to implement (Hilden & Pressley, 2006), there must be frequent professional-development support, especially for teachers new to strategies instruction. Ideally, this support would include both workshops and in-class coaching by supervisors, principals, or instructional coaches, who support staff in employing approaches for teaching and reinforcing strategies with their students.

IMPLICATIONS FOR EDUCATORS

Despite ample research evidence upon which to base decisions about strategies instruction and despite the many college textbooks published since 1995 that introduce pre-service teachers to strategies instruction, strategies instruction is not commonplace in K-12 classrooms in the United States.. It is particularly absent in content-area classes such as mathematics, social studies, and science. That the need for strategies instruction is being recognized is evidenced by the burgeoning number of commercial programs to teach general and specific strategies. The drawback to these commercial programs is that, although many attempt to address strategies instruction, they do so outside the context of the core curriculum where these strategies need to be applied. For example, only 12 of the 48 programs reviewed by Deshler and colleagues (2007) were identified as core curricula, whereas 36 were designated supplemental or remedial intervention programs. An alternative to these commercial programs is for teachers to provide strategy instruction as an integrated part of all mainstream language arts and content-area instruction with the goal of enabling all levels of learners to participate in courses with more challenging content.

In order for the United States to produce young people who are well prepared to succeed in whatever they undertake, every teacher at every grade level in every domain must become a strategies teacher. Strategies instruction needs to be adopted across the curriculum and throughout schools and school districts. It needs to begin when children enter school and continue through 12th grade. Because the need for strategies is often specific to each discipline and transfer between disciplines is not automatic, students should receive instruction in strategies for reading, writing, and learning that is differentiated for each content area (Deshler, et al., 2007). Ongoing professional development and support for strategies teachers are keys to the success of a school-wide effort to make every teacher a strategies teacher and every student a self-regulated strategy user.

Irene W. Gaskins

STRATEGY DEVELOPMENT

A strategy is a purposeful action, or sequence of actions, executed in the interest of achieving a goal. The mistaken idea that children do not exhibit strategies prior to school

age arose from studies asking preschool and older children to remember a set of items (for review, see Pressley & Hilden, 2006). Preschoolers did no better in remembering the items than they did when merely asked to look at them. Older children asked to remember the items, in contrast, were likely to employ strategies, such as organization or rehearsal. But this finding did not mean that children do not use strategies until they are 7 or 8 years old. An infant who uses a stick to bring a toy within reach is employing a strategy to reach a goal. The important questions are what strategies is a child able to employ, what is the degree of conscious control under which strategies operate, does the child know to apply the strategy or can the child be taught when and how to do so, and can strategies be employed more effectively to aid performance.

Strategies are not autonomous, multi-purpose tools stored away in a toolkit and brought out and applied when needed. Most often, people are unable to say definitively that a child either has or lacks possession of a particular strategy. Instead, strategies are linked to the contexts in which they are employed and the goals they serve. A child may exhibit a strategy in one context and not in another seemingly equivalent one.

Children's memory may differ, for example, when asked to retrieve a list of items from a mock grocery store and when asked to memorize a list of words. Multiple factors, however, are likely to contribute to such differences (Weissberg & Paris, 1986). The use of deliberate strategies, such as rehearsal, is one factor, but additional possibilities need to be weighed. These include the differing goal (and hence motivational) structures linked to the tasks and the differing familiarity of the task materials and the task activity itself. Moreover, these different contributors themselves interact with one another. A powerful memory strategy, for example, is elaboration, in which an association is formed between separate entities by identifying a theme that links them (e.g., the digit sequence 312 is remembered as a telephone area code or a batting average). In order to make use of this strategy, however, the learner needs to be familiar with such content domains.

In classroom settings, teachers need to be sensitive to these contexts of strategy use. A strategy may appear in one context but not another. A child faced with multiplying three times five, for example, may use a successive-addition strategy of laying out three groups of five objects and adding them. When the child later encounters the problem five times three, however, the child may be unable to apply the same strategy. The most common challenge teachers encounter is that students fail to apply a strategy that has been taught explicitly in one context when they later encounter problems for which it is appropriate. Simply learning how to execute the strategy is not enough.

ASSESSING STRATEGIES IN SITUATED CONTEXTS

Identifying what strategies a student is using can be difficult. Mental strategies most often are not detectable from overt performance. Asking people how they performed a task or solved a problem is one way of gaining information about strategy use, but not always a reliable one. How someone reports having solved a problem may not be identical or even similar to the mental operations that were actually performed to reach a solution. Asking the person to think aloud while engaged in the task is a better method, but it too can be misleading, because the think-aloud talk can disrupt or otherwise alter performance.

Mostly, cognitive psychologists must employ indirect methods in making inferences about strategy use, for example, by examining performance over different kinds of problems and observing response times or patterns of correctness as a way of testing hypotheses about the strategies the performer used. Nonverbal behavior (such as visual fixation patterns and gesture) may also be informative.

Teachers are in effect researchers-in-practice in the classroom, as they seek to diagnose the strategies that individual students apply to their work. They do best to treat their interpretations as hypotheses and then seek multiple kinds of evidence by talking to the child about what he is doing as well as observing his work on different kinds of problems that will either support or disconfirm such hypotheses. Teachers also need to be sensitive to two kinds of variation. One is the wide individual variation across children in how they approach a problem. Children of similar age and ability within a single classroom are likely to exhibit quite different strategies for the same task, including some that even the teacher may not have previously considered. The other kind of variation, discussed below, is variation in strategy usage within a single child.

STRATEGIC DEVELOPMENT

Adding to the assessment challenge, strategies must always be considered in relation to a task, a goal, and a situation. Still another challenge comes from the need to consider any strategy in a context of its alternatives. One of the major discoveries psychologists have made about strategies is that multiple alternative strategies applicable to a task typically exist in a learner's repertory. These strategies are of differing degrees of correctness or effectiveness. They also have different probabilities of application (see Figure 1). The instructional goal, then, is to reduce the strength, that is, probability of occurrence, of less effective strategies and increase the strength of more effective ones. New strategies do, of course, appear, but first emergence rarely indicates the beginning of consistent usage. The majority of change is thus of this

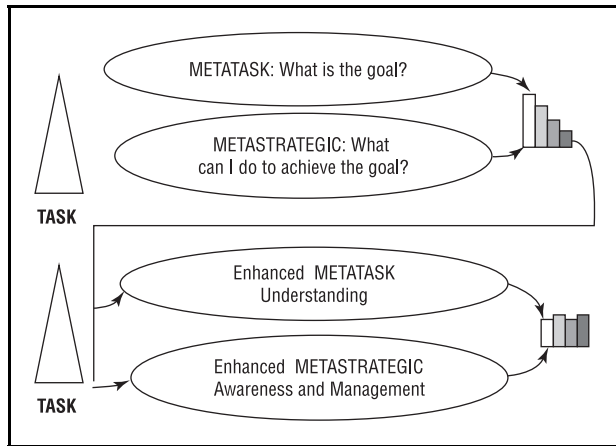

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

shifting-frequency variety. Siegler (2000) proposes an “overlapping waves” model to portray this process. A particular less-than-ideal strategy initially appears infrequently, begins to increase in frequency, enjoys a period of ascendance, and then diminishes in frequency, while another strategy follows this same course but at a later, although overlapping, time. Siegler and his colleagues tracked the course of various strategies children use in performing simple single-digit addition and subtraction problems. When faced with adding nine plus three, a first-grade child may first count one subset, then the other, and then the entire set, to produce the answer, twelve—an unnecessarily burdensome and inefficient strategy. Asked to carry out a series of such calculations, the child may after a time discover a more efficient strategy which Siegler calls the Min strategy which involves simply counting up from the first addend, i.e., “ten, eleven, twelve,” and requires enumerating only the second subset. Students may use these two (and several other) strategies as they tackle a set of problems. Over time, however, use of the less efficient strategy diminishes in frequency and use of the more efficient strategy increases.

What is entailed in this change process? Microgenetic studies (Kuhn, 1995; Siegler, 2006), in which an individual is observed engaged in the same or a similar set of problems over an extended period of weeks or months, show that the exercise afforded by this rich problem environment is sufficient to induce strategy change in a majority of cases, enabling researchers to examine its characteristics. One point that has become clear is that two distinct components are involved. The more familiar is the desired increasing strength of the more advanced strategy or strategies. But equally important is inhibition of less advanced strategies. In postulating mechanisms,

Siegler (2000, 2006; Siegler & Jenkins, 1989) emphasized the need for associations with the more frequent, less effective strategies to be weakened, as well as associations with more effective strategies strengthened.

Consistent with such a model is the finding that strategies when they first appear may not be used effectively enough to enhance performance. Researchers studying the development of memory strategies have in fact found this to be the case, giving rise to what has been called a *utilization deficiency*. A strategy such as categorization (of the to-be-remembered items), for example, even (or especially) if it has been explicitly taught, may not be used when a child later is free to approach a memory task as the child chooses, or, if it is used, may fail to improve or even diminish performance. The educational implication is that new strategies must be included in the repertory with sufficient frequency so as to allow them to be practiced, consolidated, and perfected until the user is able to experience their utility.

METASTRATEGIC DEVELOPMENT

While similarly emphasizing the relinquishment of less effective strategies as a more formidable obstacle than strengthening new ones, Kuhn and colleagues (Kuhn, 2001; Kuhn & Dean, 2004) proposed that knowledge at a meta-level is as important as that at the performance level and plays a major role in what happens there. The meta-level entails understanding of strategies—recognizing what they do or do not buy one in relation to task goals. Portrayed in the right side of Figure 1 (Kuhn, 2001) are the strategies that co-exist and are available for use (analogous to Siegler’s “overlapping waves” model). In the progress depicted from the upper to the lower half of the diagram in Figure 1, the less effective strategies to the left become less frequent and the more effective strategies to the right more frequent (in this case, yielding a temporary, transitional result of all strategies of roughly equal strategy). Implicated in this change are the meta-level operators that appear in the center of the diagram, representing the individual’s understanding of the task goal, understanding of the strategies the individual has available to apply, and awareness of the need to coordinate the two in selecting a strategy. Feedback from the performance level should enhance meta-level understanding, further enhancing performance, in a continuous process.

Kuhn and colleagues have made use of this model in research on the scientific thinking of children and adults, in particular how they coordinate their own preexisting beliefs with new evidence and draw conclusions about the causal roles of various factors in producing an outcome. Even many adults have difficulty *bracketing*, that is, holding in suspension, their own beliefs in interpreting new evidence. Community college students, for example, were

presented data regarding an experiment conducted by a school district on ways to improve reading instruction (Kuhn, Katz, & Dean, 2004). Three factors were investigated: a new reading curriculum, teacher aides, and reduced class size. Among six outcomes students were asked to examine were these two:

Classrooms with the new reading curriculum and teacher aides reported an outcome of greatly improved.

Classrooms with the new reading curriculum, teacher aides, and reduced class size reported an outcome of greatly improved.

Application of a control of variables strategy (in which all variables but the one being investigated are held constant) would dictate the conclusion that reduced class size played no role in the outcome.

Although some students did apply this strategy and come to the appropriate conclusion, a good number did not. One common response reflected the inference strategy that anything present in the context played a role in the outcome. For example, in one student's words: "Yes (class size makes a difference) because this class had it and they improved."

Other students, despite explicit instructions to interpret the presented data, ignored it and relied on their own preexisting knowledge, leading them to offer responses like this one: "Yes (class size makes a difference) because the numbers of children are small so they can learn faster and better."

To apply the more advanced, scientifically correct strategy individuals need to have good metastrategic control over their own thinking. In a problem like this one, this control makes it possible to monitor and manage the dual representations of the evidence and one's own knowledge state, as well as the cognitive strategies that are involved in coordinating them.

MANAGING ONE'S OWN LEARNING

How can teachers promote strategy development? The evidence suggests that a rich problem environment, in which students are given frequent and dense opportunities to engage problems requiring more advanced strategies will in a majority of cases lead to improvement in strategy use (Kuhn et al., 1995; Dean & Kuhn, 2007). Teachers can assist by supporting students' inclinations to take charge of their own learning. This points leads back to the contextual message with which this discussion began. If students develop their own firm understandings of what they are undertaking to learn in a particular situation and why, they are more likely to take charge of finding the most effective ways to enable them to

accomplish the job (Kuhn, 2005). This meta-level awareness and management in turn enhances the likelihood of transfer of strategies to new contexts.

The directions in which individual development progresses are consistent with the growing metastrategic capabilities that older children begin to display (Kuhn & Franklin, 2006). Older children and adolescents are less pliable than young children. They are more likely to question, and they want to try things their way. Expressed differently, they want to assume control of what they do. Growing cognitive and social skills make them more able to do so, and the indications are that in academic settings teachers should give them the space to try their own approaches to problems, to collaborate with others and to revise their strategies as warranted, and to gain from the experience that doing so affords.

STUDENT EMOTIONS

The classroom is an emotional place. The fact that learning and achievement are critical for students' educational careers implies that academic activities and attainments

often arouse intense emotions. Relevant achievement emotions include positive emotions such as enjoyment of learning, hope, and pride, as well as negative emotions such as anger, anxiety, shame, or boredom in class. Due to the interactive nature of classroom settings, social emotions such as admiration, contempt, or envy can also play a major role in these settings. Furthermore, emotions are functionally important by influencing students' academic motivation, behavior, performance, health, and personality development. Nevertheless, as of 2008, there still was a lack of empirical research on student emotions. Research has thoroughly examined students' test anxiety since the 1950s (Zeidner, 1998, 2007) and has produced cumulative knowledge that can inform educational practice. There is little research on student emotions other than anxiety, however, implying that it is difficult to draw firm conclusions for most emotions experienced by students (Schutz & Pekrun, 2007).

DEFINITION AND ASSESSMENT OF EMOTION

Emotions are reactions to significant events and objects. Serving the preparation and adaptive organization of subsequent perception, cognition, and action, emotions are defined as involving multiple coordinated processes (Lewis & Haviland-Jones, 2000). Important components include the following. (1) Affective components comprise emotional feelings that are physiologically bound to the activation of subcortical systems such as the amygdala (e.g., uneasy, nervous feelings in anxiety experienced before an exam). (2) Cognitive components involve emotion-specific thoughts (such as worries about the threat of failing an exam). (3) Physiological components serve the preparation of action (e.g., peripheral physiological activation in anxiety, as indicated by symptoms such as increased heart rate, respiration rate, and sweating). (4) Motivational components comprise behavioral impulses and wishes (e.g., avoidance motivation in anxiety). (5) Expressive components include facial, postural, and vocal expression of emotion.

Due to the multi-component nature of emotion, there are various ways to assess student emotions. Self-report instruments assess self-perceptions of emotion. In test anxiety research, questionnaires such as the Test Anxiety Inventory (TAI; Spielberger, 1980) play an important role. An instrument measuring various achievement emotions experienced by students is the Achievement Emotions Questionnaire (AEQ; Pekrun, Goetz, Titz, & Perry, 2002). Recordings of physiological processes such as heart rate, respiration rate, or changes of skin conductance are used to infer emotions from their peripheral physiological components. Brain imaging

techniques such as EEG and fMRI serve to identify central physiological processes underlying emotions. Finally, emotions can be assessed by observation of facial and postural expression. However, emotion observation is not an easy task with students beyond the early elementary years who control emotion expression by adhering to socially defined display rules.

CATEGORIES AND DIMENSIONS OF STUDENT EMOTIONS

Two distinct ways of describing emotions are provided by categorical and dimensional approaches. In categorical approaches, qualitatively different types of discrete emotions are differentiated, such as enjoyment, anger, anxiety, or boredom. This approach allows taking into account the unique patterns of components and functions that are typical for different emotions. Within the dimensional approach, a small number of dimensions are held to be sufficient to describe human emotion. Two important dimensions are valence (positive versus negative, or pleasant versus unpleasant) and activation (activating versus deactivating). Categorical and dimensional approaches can be integrated in hierarchical models that regard discrete emotions as lower-level factors, and affective dimensions as higher-order factors describing common properties of discrete emotions (Feldman, Barrett, & Russell, 1998).

The two dimensions valence and activation can also be used to classify students' achievement emotions (Pekrun, 2006; see Table 1). Achievement emotions are defined as emotions that relate to achievement activities (such as academic learning) and their outcomes (such as academic success and failure). The two dimensions render four broad categories of achievement emotions: (1) activating positive emotions (e.g., joy, hope, pride); (2) deactivating positive emotions (e.g., relief, relaxation); (3) activating negative emotions (e.g., anger, anxiety, shame); and (4) deactivating negative emotions (e.g., hopelessness, boredom).

In addition, achievement emotions differ according to their object focus, relating either to achievement activities such as learning, or to the success and failure outcomes of these activities. Furthermore, some achievement emotions render an affective self-evaluation by linking positively versus negatively valenced activities and outcomes to the self (e.g., pride after success and shame after failure). Self-evaluative emotions are critical for students' development of self-worth (Covington & Berry, 1976).

Taxonomy of achievement emotions				
Object focus	Positive		Negative	
	Activating	Deactivating	Activating	Deactivating
Activity (Learning)	Enjoyment	Relaxation	Anger	Boredom Frustration
Outcome (Success/Failure)	Joy Hope Pride Gratitude	Contentment Relief	Anxiety Shame Anger	Sadness Disappointment Hopelessness

IMPORTANCE OF STUDENT EMOTIONS FOR ACADEMIC LEARNING AND PERFORMANCE

Two lines of evidence suggest that students' emotions profoundly affect their learning and performance. The first line of evidence originates in experimental mood research, the second in situated field studies directly analyzing students' emotions. Experimental mood research has shown that mood and emotions facilitate mood-congruent memory processes, such that positive self-related information is more easily stored and retrieved when in a positive mood and negative information when in a negative mood (e.g., Olafson & Ferraro, 2001). By implication, a positive mood can enhance students' motivation to approach learning tasks, whereas a negative mood can trigger mood-congruent avoidance motivation. Furthermore, the findings indicate that positive versus negative mood can promote different styles of information processing. Whereas creative, flexible, and holistic ways of thinking are facilitated by a positive mood, more analytical, rigid, and detailed ways of processing of information can be enhanced by a negative mood (Lewis & Haviland-Jones, 2000).

The ecological validity of these experimental findings, however, may be limited due to differences between the laboratory and real-life classroom situations, including ethical constraints preventing an induction of more intense emotions in the laboratory. Therefore, field studies have directly addressed the effects of students' emotions as experienced in classroom situations. Most of these studies focused on students' test anxiety (summaries in Zeidner, 1998, 2007). Research on test anxiety has shown that anxiety impairs performance on complex or difficult tasks that demand cognitive resources (e.g., difficult mathematical tasks). Performance on easy and less complex tasks is not impaired or enhanced. Interference and attentional deficit models have been proposed to explain negative performance effects of anxiety. These models assume that anxiety involves task-irrelevant thinking which reduces task-related attention thus interferes

with performance on tasks requiring attentional resources: Students who worry about possible failure cannot focus their attention on learning.

In line with findings on task-related effects, test anxiety correlates negatively with students' academic achievement, typically explaining about 10% of the variance in achievement scores (Hembree, 1988). However, these correlations should be interpreted cautiously. First, they may be due to effects of failure on the development of students' anxiety, rather than effects of anxiety on achievement. Second, correlations were not uniformly negative across studies and individuals. Zero and positive relationships were found as well. One reason may be the ambiguous motivational effects which anxiety can exert: Anxiety reduces students' interest and intrinsic motivation, but it can also motivate students to invest extra effort to avoid failure. In individual cases, these motivating effects can be so strong that negative effects on attention and intrinsic motivation are compensated. From an educator's perspective, however, any positive effect of anxiety in an individual student is certainly outweighed by the negative effect on subject-matter interest and academic performance in the majority of students.

The available evidence for effects of student emotions other than anxiety is limited. For positive emotions such as enjoyment of learning, positive correlations with academic achievement have been reported (Pekrun et al., 2002). For anger and shame, findings suggest that overall relationships with students' achievement are negative. As with anxiety, however, the effects need not uniformly be negative. For example, in students who believe in their capabilities, shame about failure on an exam can fuel motivation to invest more effort in the future (Turner & Schallert, 2001). In contrast, findings on boredom and hopelessness suggest that these two emotions are just detrimental by exerting negative effects on cognitive resources, motivation, information processing, and any kind of academic performance (Pekrun et al., 2002).

In sum, the available evidence implies that it would be inappropriate to assume that positive emotions always exert positive effects and negative emotions always negative effects. Rather, the effects depend on the mediating processes and specific task demands under consideration. More specifically, positive activating emotions such as enjoyment of learning likely are beneficial for students' learning and performance under most task conditions. Conversely, negative deactivating emotions such as hopelessness and boredom can be assumed to be devastating to any kind of academic performance. The effects of positive deactivating emotions such as relief and relaxation, however, probably are more ambiguous. Similarly, negative activating emotions such as anxiety, shame, and anger can exert ambiguous effects by reducing attention and interest, but also by being able to strengthen extrinsic motivation as well as more rigid modes of information processing such as simple rehearsal of learning material. Therefore, negative activating emotions can enhance performance in specific cases, although their average affects across students are negative.

INDIVIDUAL ANTECEDENTS AND DEVELOPMENT OF STUDENT EMOTIONS

Students' achievement-related appraisals are important proximal determinants of their emotions. The impact of factors such as achievement goals and gender likely is mediated by students' appraisals. Also, the development of students' emotions largely depends on the development of their achievement-related thinking.

The impact of appraisals on anticipatory anxiety has been addressed by R. S. Lazarus's transactional stress model, and their impact on emotions following success and failure by B. Weiner's attributional theory. The transactional stress model (Lazarus & Folkman, 1984) assumes that individuals first evaluate the threat implied by a stressful situation such as an exam ("primary appraisal") and then judge the possibilities of coping with the situation ("secondary appraisal"). In case of threat and insufficient perceived control over the situation, anxiety is assumed to be instigated. Weiner's 1985 attributional theory proposes that achievement outcomes immediately produce "attribution-independent" emotions such as happiness after success and frustration after failure. These emotions do not need any more cognitive elaboration. In contrast, attribution-dependent emotions are shaped by the causal attribution of the outcome. Pride is assumed to depend on an attribution of success to internal factors (such as ability). Shame and guilt are induced by failure that is attributed to internal factors that are subjectively controllable (such as lack of effort). Gratitude is expected to be aroused by an attribution of

success to external factors that are under control by others (e.g., help), and anger by attributions of failure to such factors. In line with Lazarus's and Weiner's theories, empirical research has corroborated that indicators of subjective lack of controllability, such as low self-concepts of ability and failure expectancies, are related to students' anxiety and their attributions of success and failure to emotions such as pride, shame, guilt, and anger (Heckhausen, 1991; Zeidner, 1998, 2007).

Different appraisal theories of achievement emotions, such as Lazarus's and Weiner's theories, are complementary rather than mutually exclusive. The control-value theory of achievement emotions (Pekrun, 2006) aims at integrating the assumptions of different theories. In addition, whereas previous theories have focused on outcome-related emotions such as anxiety, pride, and shame, the control-value theory also addresses activity-related emotions such as enjoyment and boredom experienced during learning. The theory assumes that students experience emotions when they feel in control of, or out of control of, activities and outcomes that are subjectively important to them, which suggests that control appraisals and value appraisals are the proximal determinants of their emotions. Occurrence and intensity of achievement emotions are seen as a joint product of these two kinds of appraisals. For example, anxiety is seen to be induced when the outcome of an exam is perceived as not being sufficiently controllable, but subjectively important. Conversely, if a student feels in control and does not expect failure or does not care about the exam, there is no need to be anxious. Similarly, enjoyment of learning is seen to be instigated if a student feels competent to master the material and values the material. If the student feels incompetent or is disinterested, negative activity emotions such as boredom are induced rather than enjoyment.

Achievement goals likely influence students' emotions by shaping emotion-inducing appraisals. Mastery goals can focus attention on the controllability and positive value of achievement activities. Performance-approach goals can facilitate positive appraisals of success, while performance-avoidance goals can sustain appraisals of the uncontrollability and negative value of failure. In line with these assumptions, empirical evidence shows that students' mastery goals relate positively to their enjoyment of learning and performance-avoidance goals to their anxiety (Linnenbrink & Pintrich, 2002; Pekrun, Elliot, & Maier, 2006).

Similarly, the impact of factors such as gender, race, and culture is likely mediated by their influence on students' appraisals of achievement. Specifically, while there is too little research on the impact on race and culture to draw firm conclusions, there is consistent evidence showing gender differences in achievement emotions. Anxiety

research has shown that mean scores for achievement-related anxiety are higher for female than for male students. This is especially true for students' anxiety in mathematics. Gender differences in mathematics anxiety, however, are at least partially due to lower self-concepts of ability for female students in this domain (Frenzel, Pekrun, & Goetz, in press), suggesting that these gender differences are mediated by students' appraisals.

Finally, congruency between appraisals and emotions has also been found for the development of achievement emotions across students' educational career. Developmental research has shown that the occurrence of cognitively mediated emotions (such as pride and shame) in the preschool years is linked to the level of cognitive development (Heckhausen, 1991). Beyond the preschool years, all major achievement emotions are experienced by students. Subsequent development over the school years likely depends on the development of individual appraisals of capabilities and the subjective value of academic achievement. For test anxiety, research has shown that average levels of anxiety are low at the beginning of elementary school, increase substantially over the elementary school years, and remain at high levels throughout the middle school, high school, and university years (Hembree, 1988). This finding is congruent to the high levels of students' self-concepts of ability that are prevalent at the beginning of schooling and are adjusted downward during elementary school.

REGULATION AND THERAPY OF EMOTIONS

Emotion regulation involves up-regulating adaptive emotions such as enjoyment of learning and down-regulating maladaptive emotions such as anxiety. Cognitive competencies for doing so have been labeled emotional intelligence (Matthews, Zeidner, & Roberts, 2002). Concerning student emotions, research has focused on students' regulation of test anxiety (i.e., coping). Three broad categories of coping strategies have been identified (Zeidner, 1998, 2007). Emotion-oriented coping aims to reduce anxiety without changing the situation (e.g., by using relaxation techniques, taking drugs, or changing appraisals). Problem-oriented coping reduces anxiety by attempting to solve the problem (e.g., by investing effort in preparing an exam). Avoidance-oriented coping implies escaping the situation behaviorally or mentally (as implied by procrastination, absenteeism, and dropping out of school). In an academic achievement context, problem-oriented coping often is most adaptive. However, emotion-oriented coping can be adaptive as well (e.g., in situations providing no opportunities for successfully solving the problem).

Similarly, therapy of maladaptive student emotions can aim at directly changing the emotion or at changing underlying causal factors. Therapy of test anxiety has been researched most often and is among the most successful kinds of psychotherapy as of the late 1990s (Zeidner, 1998). Emotion-oriented treatment includes anxiety induction (e.g., flooding), biofeedback procedures, relaxation techniques, and systematic desensibilization. Cognitive therapies modify anxiety-inducing control appraisals, value beliefs, and styles of self-related thinking. Examples are cognitive-attentional training and cognitive restructuring therapy. Study-skills training teaches students to use task-oriented strategies of learning enabling them to be academically successful, thus alleviating their anxiety. Finally, multimodal therapies integrate several of these procedures.

Cognitive and multimodal therapy proved to be especially effective, both for reducing test anxiety and for improving academic performance. For students with deficits of learning strategies, study-skills training also turned out to be successful. Therapy focusing exclusively on emotion-oriented procedures is successful in terms of reducing anxiety but less effective as to students' academic improvement (Zeidner, 1998).

THE ROLE OF THE CLASSROOM CONTEXT AND IMPLICATIONS FOR EDUCATORS

Research in the late 1990s and early 2000s has focused on individual functions, antecedents, and therapy of student emotions. The role of classroom instruction remains largely unexplored. Again, research on test anxiety is an exception. Judging from test anxiety studies (Zeidner, 1998, 2007) and assumptions of appraisal theories (Pekrun, 2006), the following factors that are under the control of educators likely are important for the development of students' emotions.

1. Cognitive quality of instruction. Factors reducing students' perceived control, such as lack of structure, lack of clarity, and excessive task demands, are known to enhance students' test anxiety. With exams as well, lack of structure and transparency has been shown to contribute to students' anxiety (e.g., lack of information on demands, materials, and grading practices; Zeidner, 1998). Conversely, well-structured instruction and clear explanations likely contribute to adaptive student emotions by raising students' competencies and feelings of control. By implication, adaptive student emotions likely can be fostered, and maladaptive emotions reduced, by raising the cognitive quality of instruction.

2. Motivational quality of instruction. Teachers deliver direct messages conveying academic values, as well as more indirect messages implied by their behavior. Two ways of inducing values and related emotions may be most important. First, if learning environments meet the needs of students, positive activity-related emotions likely are fostered. For example, learning environments that support cooperative learning should help students to fulfill needs for social relatedness, thus making learning enjoyable. Second, teachers' own enthusiasm can facilitate students' adoption of positive emotions by way of observational learning and emotional contagion (Hatfield, Cacioppo, & Rapson, 1994).
3. Support of autonomy and self-regulated learning. Learning environments supporting students' self-regulated learning can be assumed to increase their sense of control and related positive emotions. In addition, such environments can foster positive emotions by meeting students' need for autonomy. However, these beneficial effects probably depend on the match between students' competence and individual need for academic autonomy, on the one hand, and the affordances of these environments, on the other. In case of a mismatch, loss of control and negative emotions can result. By implication, teachers should attend to matching demands for autonomy to students' competencies and needs.
4. Goal structures and achievement expectations. Academic achievement can be defined by standards of individual mastery, by normative standards based on competitive social comparison, or by standards pertaining to cooperative group performance instead of individual performance. These different standards imply individualistic (mastery), competitive (normative performance), and cooperative goal structures in the classroom (Johnson & Johnson, 1974). Goal structures and grading practices determine students' opportunities for experiencing success and perceiving control, thus influencing their emotions. Specifically, competitive goal structures imply, by definition, that some students experience success, whereas others have to experience failure, thus increasing levels of anxiety and hopelessness. Similarly, the demands implied by excessively high achievement expectancies of teachers and parents can lead to lowered control perceptions and related negative emotions. The available evidence corroborates that competitive classroom climates and excessive achievement expectancies correlate positively with students' test anxiety. Accordingly, as seen from an emotion perspective, educators should adapt expectancies to students' competencies and should refrain from using

goal structures which induce individual competition between students.

5. Feedback and consequences of achievement. Research suggests that cumulative failure feedback is a major factor underlying students' test anxiety (Zeidner, 1998). Success experiences likely strengthen perceived control and related positive emotions, whereas repeated failure can undermine subjective control and, therefore, instigate negative emotions. In addition, the perceived consequences of success and failure are important. Positive future-related student emotions can be increased if academic success is seen to produce beneficial long-term outcomes (such as future occupational chances). Negative outcomes of academic failure, by contrast, can increase students' achievement-related anxiety and hopelessness. By implication, providing success experiences, defining mistakes as opportunities for learning rather than as personal failure, and linking attainment to beneficial outcomes also is important for helping students to develop adaptive emotions.

SUBJECTIVE TEST ITEMS

Subjective test items are more commonly called constructed response (CR) items. They require examinees to create their own responses, rather than selecting a response from a list of options (American Educational Research Association, American Psychological Association, and National Council on Measurement in Education, 1999). No single wording (or set of actions) can be regarded as the only correct response, and a response may earn full or partial credit. Responses must be scored subjectively by content experts. The term *constructed response item* may refer to an essay item or performance assessment. Measurement experts traditionally distinguish between two variations of these subjective item types: the restricted response item and the extended response item.

Restricted response items. On restricted response items examinees provide brief answers, usually no more than a few words or sentences, to fairly structured questions. An example in seventh grade science could be: Why are day lengths shorter in December than in July in the northern hemisphere?

Extended response items. Extended response items require lengthy responses that count heavily in scoring.

Ideally these items focus on major concepts of the content unit and demand higher level thinking. Typically examinees must organize multiple ideas and provide supporting information for major points in crafting responses. An example of such an item from 12th grade literature might be: The title of Steinbeck's novel, *The Winter of Our Discontent*, is found the opening line of the Shakespeare's play, *Richard III*. Having read both works, explain why you do, or do not, think this title is appropriate. Support your reasoning by comparing main characters, plots, and use of symbolism in these two works.

Performance assessment, as conceived in personnel psychology, requires the examinee to create a product or deliver a performance in a real world situation or simulation that could be evaluated using specified criteria. Raters typically score the performance using checklists or rating scales (Fitzpatrick & Morrison, 1971). When educators transported this procedure to classroom settings, their early performance exercises reflected this definition as shown in the following examples: determine the cost of carpeting a classroom, given a tape measure and carpet cost per square foot; determine the chemical composition of an unknown powdered compound.

Gradually, educators' views of performance assessment evolved to include pencil and paper items couched in real-world contexts. Coffman (1971) successfully argued that an essay item could be a performance assessment in some content areas. In performance assessments in the early 2000s, examinees may respond to questions containing diagrams, data tables, written scenarios, or text passages, but quite often their responses are written essays. In modern usage, the defining characteristic of a performance assessment is that it requires behaviors that are meaningful end-products of instruction derived from content standards (Lane & Stone, 2006). Performance assessments may also include portfolios or assigned out-of-class projects, but the principles for construction and scoring are the same as for essay items.

CONSTRUCTING THE ITEM

Content standards and test specifications operationally define the domain of subject matter knowledge and levels of cognitive complexity that are sampled by the achievement test items. Within these parameters, the test developer must develop the questions (or prompts), create scoring rubrics (or keys), and plan the scoring process. Welch (2006) provides a comprehensive summary of this process.

Developing the prompt. The prompt for a subjective item poses a question, presents a problem, or prescribes a task. It sets forth a scenario or set of circumstances to provide a common context for framing responses. Action verbs direct the examinee to focus on the desired behavior (e.g., solve,

interpret, compare, contrast, discuss, or explain). Appropriate directions indicate expected length and format of the response, allowable resources or equipment, time limits, and features of the response that count in scoring (e.g., originality, organization, grammar, labeling diagrams, or numeric precision; see Gronlund & Linn, 1995).

Creating the scoring rubric. Scoring rubrics are usually analytic or holistic in nature. For an analytic rubric the item writer lists desired features of the response with a number of points awarded for each specific feature. A holistic rubric provides a scale for assigning points to the response based on overall impression. A range of possible points is specified (e.g. 0-8 or 0-3), and verbal descriptors are developed to characterize a response located at each possible point on the scale. Illustrative responses that correspond to each scale point are often developed or selected from actual examinee responses. These exemplars are called anchor papers because the scorer uses them as benchmarks for comparison when deciding where an examinee's response falls on the score scale.

Scoring responses. During subjective scoring at least four types of rater errors may occur as the rater (a) becomes more lenient or severe over time or scores erratically due to fatigue or distractions; (b) has knowledge or belief about an examinee that influences perception of the response; (c) is influenced by the examinee's good or poor performance on items previously scored; or (d) is influenced by the strength or weakness of a preceding examinee's response. To reduce these effects, a scoring process recommended for classroom teachers includes the following:

1. Mask student names to facilitate "blind" scoring;
2. Use the key on a trial basis for a small sample of papers and revise as necessary;
3. Grade all responses to a single item at one sitting if possible;
4. Shuffle papers between scoring different items so that examinees' responses are scored in varying order;
5. Mask the scores after initial scoring and rescore at least a sample of responses.

In large-scale testing programs, many raters participate in the scoring process. Prior to scoring, raters are trained to use common standards in extensive practice sessions using previously scored anchor papers. During scoring, each response is typically scored by at least two raters. Rater performance is monitored throughout the scoring process (Lane & Stone, 2006).

PERSISTENT ISSUES IN CONSTRUCTED RESPONSE TESTING

Using constructed response items presents issues that do not arise with objective item formats. Lane and Stone (2006) identify and discuss a number of these, but a few selected examples are as follows: Should the assessment present a few important tasks that demand complex, lengthy responses or more items, requiring briefer responses that provide broader sampling of the content and more reliable scores? Should examinees have a choice of prompts or should all respond to the same prompts? Does handwriting quality affect scores? Should examinees have a choice between handwriting or composing their responses at a computer keyboard? Do electronic scoring programs yield comparable results to those of human raters?

Such questions spark continuing debate for two reasons. First, research results from published studies on the issue may be conflicting or may not apply to other testing situations or populations. Second, these issues involve often value judgments rooted in differing educational philosophies. The final decision on such issues in a specific situation should rest on a rationale that weighs available research evidence, viewpoints of stakeholders, and possible consequences.

EVALUATING THE ITEMS

Despite the item writer's best efforts, subjective item prompts and rubrics will contain flaws. The most serious flaws are: mismatch to the content standards; ambiguity of wording; incorrect information in rubrics; inappropriate level of difficulty; content or wording that is offensive to some examinees, and potential for creating gender or ethnic bias due to the problem context or particular wording. Classroom teachers may ask colleagues to review a draft of items and critique them for such flaws. In large scale testing programs such reviews are conducted by multiple independent panels of experts (Welch, 2006).

After item administration, the examinees' numeric scores on each item provide a data set that can be analyzed to determine if the item functioned properly. This analysis typically includes computations of (a) mean item score and distribution statistics; (b) rater consistency indices (i.e., percentage of examinees receiving identical and contiguous scores from multiple raters or the correlations between the raters' scores); (c) consistency of examinee performance across different subjective items; and (d) relationship between item score and score on an objective section of the test (Schmeiser & Welch, 2006). In large scale assessments, these analyses are conducted after the items are field tested prior to live use. Flawed items can be revised or eliminated. At the classroom level, when the item analysis reveals a problem, adjustments to

the scoring rubric can be made and responses can be rescored before examinees' scores are reported.

TEACHER BELIEFS

In 1975 Dan Lortie coined the term *apprenticeship of observation* to describe the phenomenon that the majority of teachers teach very similarly to their own teachers:

Teaching is unusual in that those who decide to enter it have had exceptional opportunity to observe members of the occupation at work; unlike most occupations today, the activities of teachers are not shielded from youngsters. Teachers tend to underestimate the difficulties involved, but this supports the contention that those planning to teach form definite ideas about the nature of the role (p. 65).

Lortie contends many beliefs teachers hold about teaching originate from personal experiences as students. Some beliefs may derive from other personal experiences such as family traditions and values, social encounters, community participation, popular culture, teacher preparation, observing teachers, professional development, and scholarly literature.

Inasmuch as they originate from personal experience, beliefs are similar to attitudes and knowledge. Much scholarly debate attempts to determine just how beliefs, attitudes, and knowledge differ. In a 1992 article, M. Frank Pajares echoed Lortie's findings and described the difficulty in distinguishing attitudes from beliefs in the

ways researchers have defined and studied them. Likewise, Patricia Alexander has described the challenges in deciphering what knowledge and beliefs have in common and how they are distinct. What is undisputed is beliefs have a motivational component and play a role in driving behavior.

Teachers' beliefs exist on many levels from global to personal and serve as overarching frameworks for understanding and engaging with the world. They can be thought of as guiding principles teachers' hold to be true that serve as lenses through which new experiences can be understood. Teachers' beliefs may be formed without evidence and sometimes in the face of contradictory evidence. They are a part of teachers' identities. Beliefs, and their influence, tend to be unexamined by teachers because many are implicit, unarticulated, or unconscious. The literature suggests failing to examine beliefs can have negative consequences as they guide practice and priorities, determine what is ignored, influence decision making, and shape what types of interactions are valued.

KINDS OF BELIEFS TEACHERS

HOLD

Fundamentally, teachers' beliefs shape their professional practice. However, the study of teachers' beliefs has been tricky because of the multi-dimensionality of beliefs and the traditional boundaries drawn in educational psychology and teacher education about which beliefs constitute a relevant subset. For example, though teachers' beliefs as parents or as members of a religious group matter, much of the literature has focused on the beliefs most directly related to classroom practice. These beliefs can be

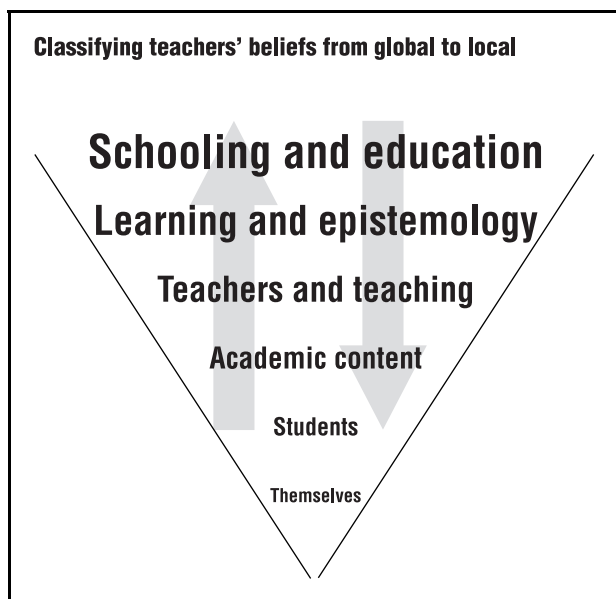

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

organized into categories, each of which operates on a different level ranging from societal to personal. Figure 1 presents these categories as an inverted pyramid with the most global beliefs located at the top and filtering down toward to the most local beliefs teachers have about who they are. Placing teachers' beliefs about themselves as the most local should not, however, suggest they are of lesser importance or that they do not impact other beliefs. In fact, change in teachers' beliefs, at any level, can create a ripple effect throughout the teachers' entire system of beliefs.

Table 1 describes each category of belief along with a working definition synthesizing the related literature and a list of scholars whose work is directly related to that category. The categories are: schooling and education, epistemology, learning, teaching and teachers, academic content, students, and themselves.

BELIEFS ABOUT SCHOOLING, EPISTEMOLOGY, LEARNING, AND TEACHING

At the most global level, teachers hold beliefs about the purpose of schooling. For some teachers, these beliefs are rooted in a holistic perspective wherein the purpose of education is to help all children reach their full potential in every facet of their lives. Other teachers' beliefs, however, are rooted in more essentialist models that position schools as places in which students acquire knowledge critical to becoming productive members of society. Still others believe schooling should envision a new society,

help students become lifelong learners, or enhance the students' individuality.

Beliefs about the role of education can filter down and impact teachers' epistemological beliefs. These include "beliefs about the nature of knowledge and the processes of knowing" (Hofer & Pintrich, 1997, p. 117). They include beliefs about what criteria should be used to determine the validity and value of different types of knowledge. When identifying their epistemological orientation, teachers must ask themselves: Is knowledge singular or multiple? Must all knowledge be consistent or is there room for contradiction? And, who can be the source of knowledge: the teacher, society as a collective, or some singular, external authority?

Just as these epistemological beliefs are shaped by beliefs about the role of schooling, teachers' beliefs about learning are influenced by their epistemological beliefs. Beliefs about learning include those related to how people learn and what it means to have learned (Hofer & Pintrich, 1997). For example, teachers who have essentialist views of education are likely to believe that only certain kinds of knowledge are valid. They, therefore, are likely to focus their efforts on having students learn those kinds knowledge. Similarly, epistemological beliefs impact teachers' understandings of what it means to teach and how teaching is best accomplished. For example, teachers who believe authority figures (e.g., teachers, doctors, scientists) are the only real sources of knowledge may adopt a more behaviorist perspective about learning. They are also likely to enact transmissionist instructional techniques, such as direct instruction, founded on the notions that teachers know and students learn when teachers give them knowledge.

Alternatively, teachers who believe the self can be a valid source of knowing are likely to structure their classrooms in ways that emphasize students' contribution to the learning process. Furthermore, these teachers tend to believe that teachers and students know and learn together and that learning happens best through dialogue and shared interaction. Discussion and discovery learning pedagogies were founded in the belief that individuals and groups can create meaningful understandings.

TEACHERS' BELIEFS ABOUT ACADEMIC CONTENT, STUDENT POPULATIONS, AND THEMSELVES

Global beliefs have local impact on teachers' beliefs about the content they teach, their students, and themselves as teachers. Susan Stodolsky and colleagues argue teachers' beliefs about academic content, particularly with regard to status, stability, sequence, and scope, shape their practice. These beliefs inform the concepts teachers emphasize, the way they order and organize material, the student understandings and misunderstandings they anticipate, and their instructional and assessment decisions.

Teacher beliefs and prominent programs of research		
Type of belief	Working definition	Eminent scholars
Schooling and education	Teachers hold beliefs about the nature and purpose of schooling including the reasons why we send children to school; what it means to educate; and what should be the ultimate goals of an (public or privately funded) education system.	Mortimer Adler, George Counts, John Dewey, Paulo Freire, Barbara Finkelstein, Maxine Greene, Eric Donald Hirsch, Jr., Bell Hooks, Nel Noddings
Epistemology	Teachers hold beliefs about the nature of knowing and knowledge including what types of knowledge are valued and what are the trusted sources of knowledge.	Patricia Alexander, Barbara Hofer, Paul Pintrich, Gregory Schraw, Gale Sinatra
Learning	Teachers hold beliefs about how people learn and the 'best' ways to support conceptual change.	Hilda Borko, James Greeno, Hugh Munby, Tom Russell
Behaviorist	Teachers who endorse behaviorist views of learning believe in the power of external forces, like rewards and consequences, to shape new learning.	Clark Hull, Ivan Pavlov, B. F. Skinner, Edward Tolman, Edward Thorndike, John Watson
Social cognitivist	Teachers who endorse social-cognitive views of learning emphasize the ways in which environmental factors work in combination with students' prior knowledge and their personal motives to create opportunities for performing different behaviors and intellectual tasks.	Albert Bandura, Dan C. Lortie, M. Frank Pajares, Barry Zimmerman
Social constructivist	Teachers who endorse social-constructivist views of learning believe in the power of culture, be it family culture, classroom culture or school culture. They view their role in the classroom as that of a gatekeeper—providing students with intellectual tools that can help them to increase their participation in the school and larger community.	Barbara Rogoff, Lev Vygotsky, Reggio Emilia Approach
Cognitivist	Teachers who endorse a cognitive view of learning emphasize the potentials and limits of students' understanding based on their prior knowledge, their memory capacity, their mental strategies, and their abilities to connect new understandings to what they already know.	Noam Chomsky, Jerome Bruner, Richard Mayer
Constructivist	Teachers who endorse a constructivist view of learning emphasize the individual nature of knowledge construction and emphasize the importance of students' experiential learning.	Paul Cobb, Maria Montessori, Jean Piaget, Virginia Richardson
Teaching and teachers	Teachers hold beliefs about what it means to be a teacher including what roles and responsibilities teachers bear, what it means to serve students, what norms and mores are appropriate for classrooms, and what instruction "should" look like.	Douwe Beijaard, Marilyn Cochran Smith, Linda Darling-Hammond, Lisa Delpit, Fred Korthagen, Lee Shulman, Nancy Zimpher
Classroom management	Embedded in teachers' beliefs about instruction are their understandings of how to best manage a classroom to promote learning. These are, in part, a reflection of their beliefs about the nature and value of student-teacher and peer interactions.	Edmund Emmer, Carolyn Evertson, Nancy K. Martin, H. Richard Milner, Leslie Soodak, Carol Weinstein, Charles H. Wolfgang
Culturally relevant pedagogy	Embedded in teachers' beliefs about instruction are their beliefs about culture in general and classroom culture specifically. These beliefs include beliefs about the role students' home culture should play in the classroom. They focus teachers' efforts on either helping students to assimilate to a predetermined culture or on facilitating students' contributions to a negotiated culture.	David Brown, Geneva Gay, Jacqueline Irvine, Gloria Ladson-Billings
Subject matter/ academic content	Teachers hold beliefs about the nature and structure of the subject matter being taught. These beliefs guide them when planning what the important ideas are in their field, how to sequence their instruction, and what standards should be used in judging student mastery.	Pam Grossman, John Guthrie, Deborah Stipek, Susan Stodolsky
Students	Teachers hold beliefs about the nature of being a student including what it means to be a good student, how students should behave, how students can best spend their time, and the nature of ideal teacher-student relationships.	Jere E. Brophy, Mary McCaslin, Robert Rosenthal, Richard E. Snow, Thomas L. Good
Individual differences in learning	Teachers' beliefs about the impact of learner differences on classroom practice are closely tied with beliefs about the nature of intelligence. They shape teachers' conceptions about the amount of their time and energy different students will require to be successful.	Scott Danforth, Carol Dweck, Howard Gardner, Leslie Soodak, Robert J. Sternberg
Individual differences in interactions	Teachers' beliefs about the nature of students' stable identity characteristics such as their gender, race, religion, or sexual orientation. These beliefs shape can their instruction and interactions with students, privileging some and marginalizing others.	Molly Blackburn, Beverly Cross, Geneva Gay, Etta Hollins, Robert Pianta, Susan Talburt
Themselves	Teachers hold beliefs about themselves in the role of teacher. These include beliefs about their identity, knowledge, capabilities, values, desires, and needs.	Robert Bullough, Jane Danielewicz, Adrienne Dixson, Gail McCutchen, Beverly Tatum, Bruce Toroff
Self-efficacy	Teachers hold beliefs about their own abilities including the extent to which they believe they can be successful in all of their teaching tasks.	Patricia Ashton, Anita Woolfolk Hoy, M. Frank Pajares
Sense of responsibility	Teachers hold beliefs about outcomes they are, and are not, responsible for in their classroom, in their school, with their students.	Thomas Gusky, Julian Rotter

Table 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

Even more local than beliefs about content are teachers' beliefs about their students. These beliefs include what it means to be a student, how students should relate to teachers, and the impact of student differences on classroom practice and culture. Scholars such as Richard Ryan, Edward Deci, and Johnmarshall Reeve assert that in order for students to assume responsibility for their own learning they must feel autonomous, competent, and connected to their classmates and teachers. Underlying their theories is the assumption that in order to be self-determined, students must have these fundamental needs met. However, their research suggests teachers' beliefs about their own need to be in control may be in conflict with students' needs.

Likewise, teachers' beliefs about whether their students need relationships with them may be in conflict with what the literature says students actually need. Robert Pianta argues that all students need to experience close relationships with their teachers. However, the literature (see Davis, 2003) suggests that teachers may regard this need as varying with students' development or social group. Similarly, the work of Jere Brophy and Mary McCaslin (McCaslin has also published under the name Mary Rohrkemper) investigates teachers' definitions of and interactions with problem students. When teachers believe the source of behavior problems is a lack of competence as opposed to an attempt to usurp control in the class, they tend to respond with more caring and are more likely to help those students achieve competence. Other researchers have explored the causes of behavior understood by teachers to be disruptive. For example, Molly Blackburn writes about the experience of lesbian, gay, and bisexual students who are perceived as disruptive but who in actuality may be expressing malcontent with an irrelevant curriculum. More generally, Jacqueline Irvine's work highlights that teachers' beliefs about the way students should behave at school may prevent them from recognizing and appropriately responding to student behavior that critiques marginalizing curriculum. Irvine introduced the concept of *cultural synchronization* to describe how teachers' beliefs about certain student groups may be in conflict with the actual motives, values, and needs of those students. Clashes between teachers' and students' beliefs may have negative instructional and interpersonal consequences.

At the most local level, teachers hold beliefs about themselves—who they are in relation to curriculum, colleagues, and students; perceived strengths and weaknesses; values; self-efficacy; and matters about which they feel responsible. These beliefs may be domain specific; teachers may hold beliefs about who they are as instructors that are different from their beliefs about themselves as classroom managers or content experts. These beliefs may be hierarchically organized such that a teacher may believe they are experts in their fields, they are strong instructors, but they struggle with classroom management. Because teachers

may weigh these domains differently (i.e., placing the most value on being a strong instructor), when asked if they are good teachers, they may respond based on a global perception that they are. Finally, beliefs may not necessarily be calibrated with actual behaviors. In her study of pre-service teachers, Carol Weinstein documented how novice teachers are likely to be unrealistically optimistic regarding their ability to manage classroom tasks.

Finally, it is important to note the majority of the literature on teachers' beliefs has been based predominantly on studies of white, middle class, female teachers (Woolfolk Hoy, Davis, & Pape, 2006). In "The Silenced Dialogue," Lisa Delpit reinforces the notion that teachers from underrepresented or marginalized populations may hold different beliefs about teaching minority students and, therefore, view themselves and their tasks very differently. One African American principal in Delpit's study expressed her experience of being ill-represented in the literature and of her majority colleagues using this literature to ignore her perspective. The principal was quoted as saying: "If you try to suggest that's not quite the way it is, they get defensive, then you get defensive, then they'll start reciting research. I try to give them my experiences, to explain . . . they don't really hear me" (Delpit, 1995, p. 22). Delpit argues alternative, and perhaps transformative, perspectives of minority teachers are not represented in the research base and deserve to be voiced.

THE IMPORTANCE OF TEACHERS' BELIEFS

In the 1960s, Robert Rosenthal (b. 1933) began examining expectancy beliefs and self-fulfilling prophecies research that has remained robust into the early 2000s. When teachers expect students to perform (i.e., high or low), they behave in differential ways that bring about the expected performance. In *Pygmalion in the Classroom: Teacher Expectations and Pupil's Intellectual Development* (1968), Rosenthal and Jacobsen documented how teachers' beliefs about student ability can be subtly manipulated such that teachers believe some students to be more able than their peers and how their beliefs about student ability affect students' actual achievement. Rosenthal's research was extended to understand systemic differences in the way teachers approach students from lower economic standing (Alvidrez & Weinstein, 1999), students in urban settings (Causey, Thomas, & Armento, 2000), and special education students (Soodak, Podell, & Lehman, 1998).

Measuring the power of teachers' beliefs about student intelligence became important. In 1973 W. Burleigh Seaver conducted a naturalistic experiment to examine the effects of teachers' expectations of students' performance given the performance of a high or low achieving sibling

in their class in a previous year. Underlying this study was the assumption that teachers expect siblings to perform similarly given their shared family context and/or genetic makeup. Using school records, and controlling for the younger siblings' actual intelligence, older siblings were classified as either high or low performers and younger siblings' performances when they had the same or different teacher were examined. "When the older sibling had performed at a high level, the expectancy group [i.e., having the same teacher] scored better than the control; when the older sibling had performed poorly, the expectancy group scored lower than the control group" (p. 337). The average size of the effects was .30 on a grade equivalency score, approximately the achievement that happens across one-third of an academic year.

Self-fulfilling prophecies, such as those about student ability, operate through two forms of messages teachers send to students: the explicit (i.e., what is consciously said) and implicit (i.e., what is unconsciously said). In 1973 Rosenthal "derived four major types of teacher behaviors that appear to be associated with [teacher] expectancy effects. These are (1) climate is the teacher warm and encouraging to the pupil? (2) feedback does the teacher offer evaluative comments on the pupil's ongoing performance? (3) input how much does the teacher try to teach the child? (4) output how many opportunities does the teacher give the child to respond?" (Hall et al., 2001, p. 163).

Teachers' beliefs are a form of subjective reality: What they believe is real and true. Their beliefs guide their decision-making, behavior, and interactions with students and, in turn, create an objective reality in the classroom, what students experience as real and true. Teachers' beliefs shape their planning and curricular decisions, in effect determining what should be taught and what path instruction should follow. Moreover, their beliefs are not always a reflection of accepted notions in the field. In a 1998 study of teachers' and students' understandings of knowledge (from prior experience and formal instruction in school) and beliefs, Patricia Alexander and colleagues found teachers and students recognize beliefs and knowledge may not overlap:

Our students and teachers in both Singapore and the United States suggest that there are those objective dimensions of one's understanding (i.e., knowledge) that are factual in nature and learned in school but of limited importance or value. In contrast, there are those personal tenets (i.e., beliefs) that may be unproven or even questioned in schools and society, but which are nonetheless true and which serve as the guiding forces in one's life. (p. 114)

These findings suggest teachers may hold beliefs that are in conflict with their physical and social realities; but

that, nonetheless, inform their practice. Moreover, these findings suggest that teachers cannot assume an understanding of another person's (i.e. another teacher or their students) decision-making even when they share a knowledge base. Teachers need to dig deeper to try to uncover the beliefs, the personal tenets that drive their own, their colleagues', and their students' behavior.

HOW TEACHERS' BELIEFS OPERATE

Essentially beliefs function in a way similar to a lens on a magnifying glass. They clarify and guide interpretation of what may be ambiguous or unfocused. Generally, teachers interpret ambiguous situations in ways that are consistent with their beliefs. Beliefs also serve as a foundation for setting goals and standards by framing what is viewed in detail and focusing teachers' attention and energy. Similarly, they delimit what is peripheral, determining what teachers do not see, emphasize, or examine. Because beliefs help teachers to make sense of what they experience in the classroom, they create meaning for teachers. Moreover, they prepare teachers to experience certain emotions by mapping pleasant feelings onto some experiences (i.e., success or failure) and unpleasant feelings onto others.

Debate continues about the extent to which teachers' beliefs and their identity as teachers are the same. The literature on teachers' beliefs suggests teachers may simultaneously hold beliefs that are inconsistent, in conflict, and even contradictory and still see themselves as a teacher. Fred Korthagen posits teachers are likely to be the most effective when their beliefs are aligned with each other and with the field.

That beliefs are intimately tied with teachers' sense of self (be it their personal identities or their teaching identities) is consistent across the literature, and, for this reason, beliefs tend to be resistant to change. In the face of information that challenges their beliefs, such as policy inducement to reform, to modify/include new populations of students, or to innovate with new technologies, teachers tend to feel threatened (Fecho, 2001; Gregoire, 2003). This reaction constitutes a fundamental challenge and, at times the paradox, of practicing and pre-service teacher education. The problem is to figure out how can teachers be encouraged to approach research in education, professional development, and policy reform with open minds.

HOW TEACHERS' BELIEFS CHANGE

There is an inherent tension in the field of teacher beliefs between the call for teachers to habitually confront and revise their beliefs and the need for teachers to identify and preserve beliefs that serve them well. On one hand, at some point teachers inevitably have some maladaptive beliefs because the nature of childhood, the demands of

society, and the curriculum change. On the other hand, there is an assumption in the literature, particularly with regard to beliefs about diverse students and best practice, that teachers' beliefs are bad and need to be changed. The danger of this thinking is that in order to protect their sense of self as good persons and as effective and altruistic teachers, teachers may defensively hold on to beliefs that do not serve their students. What appears to be a dichotomy here need not be. What teachers need to be encouraged to do is honestly face their beliefs in their entirety, evaluating which beliefs serve them, their content, and their students and which do not.

The question is what teachers should do when they confront beliefs that do not work anymore. The malleability, or persistence, of beliefs and ways to bring about belief change are highly debated issues. In general, the more beliefs are tied to a teacher's sense of self, the more they will resist change. Literature in the field of teacher education often suggests that the ideal conditions for belief change include: 1) bringing pre-existing beliefs to consciousness, 2) creating conditions in which pre-existing beliefs break down, 3) helping teachers to judge the conflict as challenging rather than threatening (Gregoire, 2003), and 4) providing teachers with the necessary time to reflect on their beliefs and reconcile them with the field and their current teaching context (Davis, 2006).

Mere awareness of beliefs may not be motivating enough to create change. Nearly all theories of conceptual change would argue that there needs to be some cognitive dissonance by which teachers see their beliefs do not work given serving a specific student population, teaching a specific concept, or enacting desired outcomes. Dissonance challenges teachers by forcing them to face failures, however small. When studying adaptive teaching Lyn Corno and colleagues (Corno & Snow, 1985; Rohrkemper & Corno, 1988) describe how adaptive teachers face dissonance and learn from it. Corno contends adaptive teaching involves monitoring which students are struggling and identifying the sources of the struggle. She argues that failures can have meaning and can transform teaching. In some cases, student failure can point to beliefs teachers have that are holding students back. Can teachers reframe failure to help themselves grow professionally? By thinking of students' struggles as "functional failures" (Rohrkemper & Corno, 1988; p. 303) teachers can modify what they are doing to help their students learn and, in doing so, help themselves to work more effectively with all students and their subject matter. What makes this so hard, according to Michelle Gregoire Gill, is helping teachers learn to interpret failure (or educational reform) as a challenge and an opportunity for growth rather than as a threat.

Perhaps the most challenging parts for administrators and teacher educators are building in the time and

providing teachers with the tools necessary to engage in productive reflection (Davis, 2006). Elizabeth Davis describes the ways reflection on beliefs can go awry and makes three recommendations. First, teachers should be encouraged to move beyond describing what they see and experience and to analyzing what is happening in their classrooms. Second, teachers should be encouraged to think about problems from an alternate perspective, particularly their students'. Third, to put an end to dichotomous thinking, teachers should be encouraged to integrate what may feel like competing tensions and create space for new solutions. Fundamentally, doing so entails a shift from either-or to both-and thinking. In other words, instead of teachers feeling like they have to choose between following their beliefs or participating in reform, when reform is important, teachers should seek ways to align their beliefs with the reform.

IMPLICATIONS FOR CLASSROOM TEACHERS

If there are three clear messages throughout the literature on teachers' beliefs, they are, first and foremost, that teachers' beliefs have profound impact on classroom life; that the beliefs that impact students are layered, multi-dimensional, sometimes implicit, and difficult to change; and that teachers who fail to examine their beliefs may bring about unanticipated consequences in the classroom. Without intending to, teachers may set aside valuable curriculum, overlook or marginalize students who need them, misinterpret students' motives or behavior, and limit their potential as professionals. Conversely, teachers who are willing to explore their beliefs, and how their beliefs relate to practice and the professional knowledge base, can capitalize on the beliefs they hold to promote students' intellectual growth, autonomy and reciprocity, and equity in their classrooms. Moreover, they create spaces for their own growth as they identify and revise beliefs that do not serve them, their students, or their schools.

TEACHER EFFICACY

The concept of self-efficacy was pioneered by Albert Bandura (1925) who characterized self-efficacy as the extent to which individuals believe they can organize and execute actions necessary to bring about a desired outcome. Self-efficacy is fundamentally concerned with the execution of control rather than the outcome action produces.

In 1984, Patricia Ashton (1946) published a groundbreaking study that fundamentally expanded the concept of efficacy to include the extent to which teachers feel confident they are capable of bringing about learning outcomes. Ashton identified two dimensions of teaching efficacy: general, the extent to which a teacher believes her students can learn material; and personal, the extent to which a teacher believes her students can learn under her instruction. Ashton argued that teachers' beliefs

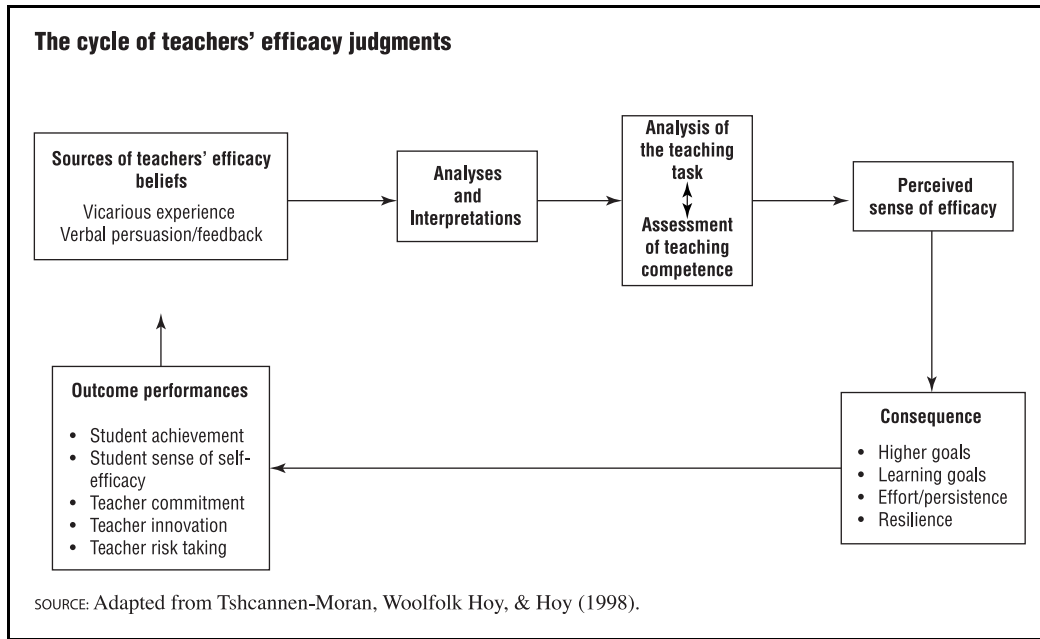

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

about their ability to bring about outcomes in their classrooms, and their confidence in teaching in general, play a central role in their abilities to effectively serve their students. Since then, studies of teaching efficacy and its inclusion in studies of teacher effectiveness have grown exponentially.

Subsequent understandings of teaching efficacy have refined Ashton's understanding of personal efficacy. In a seminal review of teacher efficacy, Megan Tschannen-Moran (1956) and Anita Woolfolk Hoy (1947) operationalized teachers' sense of control over student outcomes in the Teachers' Sense of Efficacy Scale (TSES) (Tshannen-Moran & Woolfolk Hoy 2001). Rather than thinking about efficacy as a proxy for a global sense of confidence, they defined teacher efficacy as teachers' perceptions of their resources and strategies for bringing about student behavioral and instructional outcomes. Rather than ask, "How much can you help your students think critically?" the TSES asks, "How much can you do to help your students think critically?" This minor change in wording illustrates a critical issue in teacher efficacy research: that teachers' sense of efficacy reflects the judgments they make about their capabilities given the emotional and instrumental resources they can gather in a specific context. Because teachers' judgments of their resources and strategies may vary across teaching contexts, Woolfolk Hoy argues that teachers' efficacy beliefs may not be uniform across all disciplines or even across all student populations. It is therefore important to account for context and discipline in order to accurately assess teacher efficacy.

HOW TEACHERS DEVELOP SELF EFFICACY BELIEFS

Tshcannen-Moran and colleagues (1998) developed a model of teacher efficacy identifying the ways in which efficacy judgments result as a function of the interaction between teachers' analysis of teaching task in context and their teachers' assessment of their personal teaching capabilities as they relate to the task (see Figure 1). In addition, Bandura also identified four specific sources of efficacy beliefs: mastery experiences, vicarious experiences, verbal persuasion, and arousal. Mastery experiences are direct encounters with success through engagement in a behavior that brings about a desired outcome. For example, student-teachers who facilitate laboratory experiments in which students demonstrate conceptual understanding may believe their actions led to student learning. These judgments are likely to increase their efficacy for conducting lab experiments in the future. This may be why some studies have found a connection between teacher education coursework and pre-service teacher efficacy. If student-teachers watch experienced teachers successfully facilitate laboratory experiments, they might also develop a sense of efficacy because they saw how to implement the actions necessary to bring about students' success. This would be an example of a vicarious, or observed experience leading to higher efficacy.

When student-teachers do not have opportunities to observe, their mentor teachers might remind them of the teaching skills they have developed and provide them with specific suggestions. This would be an example of

verbal persuasion, which appeals to the teacher's ability to bring about success. Finally, arousal is a physiological state involving the release of hormones that signal an individual to prepare for action. Arousal can be interpreted as both pleasant and unpleasant. On the one hand, the body's natural release of hormones while teaching can help teachers feel alert or excited to take on the challenges of the lesson. On the other hand, heavy release of hormones (as in the case of extreme nervousness) can be paralyzing rather than helpful.

Calibrating and Re-Calibrating Teacher Efficacy. There is little consistency across the literature regarding the stability of teacher efficacy over time; some studies indicate efficacy may increase over time and others suggest it may decline. What is clear is that teachers' efficacy judgments tend to calibrate when they move into new contexts. For example, Woolfolk Hoy and Burke-Spero (2005) found teacher efficacy declined as they entered the field. One explanation for possible initial declines in efficacy may be that when new teachers enter the teaching force, they encounter a "reality shock" as they confront the complexity of the teaching task. Carol Weinstein (1988) suggests this may indicate a tempering, or calibration of overly optimistic efficacy beliefs, or what she termed "unrealistic optimism." Those who continue to feel incompetent are likely to leave the field, while teachers who remain in the field appear to experience a rebound in their efficacy judgments.

THE CONTEXT AND MEASUREMENT OF TEACHER EFFICACY

Teacher efficacy beliefs are one type of belief within a system of interrelated self-beliefs. Moreover, teacher efficacy beliefs emerge, in part, as a function of teachers' global and specific judgments about themselves within the context of their classroom. In the field of teacher beliefs, there has been a lot of debate about how best to study the relationship between teachers' beliefs about themselves and the impact of these beliefs on classroom learning. In part, this is because scholars from across a variety of research traditions developed frameworks for understanding self-beliefs, with each framework critiquing the level at which we should evaluate teachers' beliefs, the domains that matter, and which judgments inevitably lead to action. In an effort to delineate what teacher efficacy is and how it should be measured Table 1 outlines conceptual distinctions among the prominent programs of research on teachers' other self-beliefs.

Although teacher efficacy is related to self-concept, self-esteem, locus of control, and sense of responsibility, it is theoretically and empirically distinct from these constructs. On a global level, teachers hold beliefs about who

they are in their classroom, their teaching self-concept, and how they feel about themselves in their classrooms, their teaching self-esteem. Teachers' self-concepts and self-esteem are considered global because they are broad, descriptive mental representations teachers hold about the work they do in their classrooms. In contrast, scholars studying teacher efficacy attempt to identify specific, task-related judgments teachers make about their ability to bring about task-specific outcomes.

Carl Rogers (1902-1987) defined self-concept as a personal understanding of the self relative to other people and environments but unaffected by tasks or contexts. Teacher self-concept goes beyond merely identifying characteristics, "I am a teacher," to classifying those characteristics, "I am a good teacher." Whereas self-concept is based upon comparative judgments, self-esteem is based upon affective judgments. Teacher self-esteem may be defined as the evaluation of each characteristic contained in teachers' self-concepts. For example, "I am good at motivating students" may be evaluated in terms of satisfaction, or the extent to which being a good teacher is desirable. Although self-esteem may change over time, it is not variable across tasks or contexts.

Scholars studying teachers' locus of control and their sense of responsibility are primarily focused on teachers' perceptions of their roles in student achievement. Role attributes are beliefs about the part a teacher can play in bringing about outcomes. Thomas Guskey (1950) characterizes teachers' perceptions of control as based primarily in the teacher (internal) or other factors (external) and variable across situations. If control over an outcome is attributed internally, individuals are more likely to engage in a behavior. The critical distinction between locus of control and self-efficacy is the emphasis on product rather than process; locus of control asserts that individuals are motivated to act based upon perception of control over the outcome. If teachers believe control lies within the student (e.g., smart/dull) or other external factors (e.g., family/community), they may be less likely to engage in actions that bring about desired outcomes even if they feel they can successfully execute those actions.

Responsibility models address teachers' underlying beliefs about who should bring about outcomes. Teachers' sense of responsibility is both an internal and external orientation deriving from perceptions of professional/ethical and personal/moral obligation. Perceptions of control and responsibility can impact teachers' efficacy judgments. In an environment where schools are becoming increasingly culturally diverse and where teachers are held strictly accountable for their students' success on standardized tests, teachers' ability to serve minority students and address politically sensitive issues is limited. Yet, many teachers are motivated to serve students who

Differentiating between teachers' sense of efficacy and their self-concept, self-esteem and self-worth

Construct	Definition	Characteristics	Sample items	Related articles
Teachers' sense of efficacy	Teachers' perceptions of their ability to accomplish specific tasks in a given context.	Task and context specific; Future-oriented; Not based on comparisons with other people or with other aspects of the self—rather question is "Can I do it?" Judgment of capability.	"How much can you do to help your students think critically?" (Instructional) "How much can you do to control disruptive behavior in the classroom?" (Classroom Management) "How much can you do to motivate students who show low interest in school work?" (Motivation) "Students would come to me when they have problems in their daily life because they know I can help." (Relationships)	Tschannen-Moran, Woolfolk Hoy, & Hoy (1998) TSES: Tschannen-Moran & Woolfolk Hoy (2001) Ho & Hau, 2004
Teacher self-concept	Global perceptions of my competence as a teacher.	Global; present orientation; includes self-efficacy and other self-judgments; based on comparisons with others (e.g., "I work with parents better than most teachers") or with self ("I'm better at lecturing than guiding group work").	"I am a good teacher." "My students learn many important things from me."	Friedman & Farber (1992) Brown (2004)
Teacher self-esteem	Global affective statements reflecting teachers' self-evaluations of their accomplishments.	Judgment of self-worth; not necessarily related to self-efficacy—can have low efficacy for a task, but not value the task, so self-esteem is unaffected.	"On the whole, I am satisfied with myself." "I wish I could have more respect for myself."	Singh (1984) Juhasz (1990) Christou, Phillipou, & Menon (2001)
Locus of control and teachers' sense of responsibility	Teachers' beliefs about their responsibility for student outcomes.	Teachers' attributions for student outcomes (Guskey). Teachers' acceptance or rejection of responsibility for implementing culturally relevant pedagogy (Kozel).	"If a student does well in your class, would it probably be: a. because that student had the natural ability to do well, or b. because of the encouragement you offered?" "It is my responsibility to ensure that all students are able to participate in every lesson." "It is my responsibility to provide accurate information about sexual orientations." (Specific beliefs about racial, religious, and social minorities)	Guskey (1988) Kozel (2007)

need the most help (Winfield, 1986). Teachers may engage in activities designed to serve such students even when they do not feel efficacious or believe the outcome is outside of their control.

HOW TEACHER EFFICACY AFFECTS CLASSROOM LEARNING

In light of so many different ways of defining teachers' beliefs about themselves, why is teacher efficacy such an important construct? Simply put, empirical studies have recognized teacher efficacy as a major predictor of teachers' competence and commitment to teaching—more powerful than self-concept, self-esteem, and perceived control. Four seminal reviews of the impact of teacher efficacy by Ross (1998), Goddard et al. (2000), Labone (2004), and Wheatley (2005) reveal consistent findings: teachers who report a higher sense of efficacy, both individually and as a school collective, tend to be more likely to enter the field, report higher overall satisfaction with their jobs, display greater effort and motivation, take on extra roles in their schools, and are more resilient across the span of their career. Moreover, the extent to which shifts in teacher efficacy take place as teachers transition into new contexts appears to depend upon the level of support in the context; greater support from administrators and colleagues buffers against declines.

Individual Teacher Efficacy. Teachers with higher levels of efficacy are more likely to learn and use innovative strategies for teaching, implement management techniques that provide for student autonomy, set attainable goals, persist in the face of student failure, willingly offer special assistance to low achieving students, and design instruction that develops students' self-perceptions of their academic skills. Moreover, Woolfolk Hoy and Davis (2005) argue that teachers who feel efficacious about their instruction, management, and relationships with students may have more cognitive and emotional resources available to press students towards completing more complex tasks and developing deeper understandings. This is because teachers with a high sense of efficacy may be less afraid of student conflict and more likely to take greater intellectual and interpersonal risks in the classroom.

Teachers' Collective Sense of Efficacy. Collective teacher efficacy is “the perception of teachers in a school that the efforts of the faculty as a whole will have a positive effect on students” (Woolfolk Hoy, et al., in press). Hoy and Miskel (2008) argue that a school's system of shared beliefs binds the teachers together and gives the school a distinctive identity. Like self-efficacy, collective efficacy is associated with the tasks, level of effort, persistence, shared thoughts, stress levels, and achievement of groups. Studies have demonstrated that higher aggregate teacher and collective efficacy is associated with increased rates of parental

involvement, increased school orderliness, teacher innovation, teacher familiarity with colleague's courses, reduced suspensions and dropout rates, and higher achievement across elementary and secondary schools. In a series of studies Roger Goddard (1966) and colleagues found the collective efficacy of a school had a greater positive impact on student achievement than the locale of the school (i.e. urban, suburban, rural) and individual student demographic variables (e.g. race, gender, socio-economic status).

IMPLICATIONS FOR TEACHERS

The literature on teacher efficacy has important implications for the induction of new teachers and the professional development of practicing teachers. Broadly, research on teacher efficacy can help teachers think about the ways in which they approach tasks in their classrooms including how accurate they are in identifying the challenge level of tasks and the extent to which they try to break down complex, challenging tasks into something more manageable. Teachers can think about the ways in which they attempt to structure their teaching tasks (e.g. selecting activities, employing new strategies/methods) in such a way that allows them to both grow professionally and feel competent. Moreover, teachers need to be reflective about the areas where they feel most and least competent. How do discrete experiences of success and failure shape their beliefs about their ability to carry out similar behaviors in the future? Teachers need to be aware that feeling incompetent may lead them to avoid important classroom tasks. Over time, teachers may purposely make decisions to avoid certain schools and students or even avoid examining data as a way to protect their sense of self. When faced with feelings of failure, teachers need to engage in active help seeking aimed at building their efficacy through mastery experiences or observing colleagues.

Preservice and Early Career. The task of teacher education is, fundamentally, to develop competent and confident teachers. Preservice teachers with little or no teaching experience may lack a sense of efficacy, and program developers need to think carefully about how to structure entry into the field in a way that promotes mastery. On the other hand, if all of their early experiences lead to success, preservice teachers may enter the field with a false, or uncalibrated, sense of efficacy because it was developed without the demands of running one's own classroom, dealing with parents and teachers or managing student problems. In a seminal paper by Rohrkemper and Corno (1985), teachers were cautioned not to ignore the value of “functional failure.” They encouraged teachers to create context in which students can learn from mistakes and learn to persist even when unsuccessful. Their work also has important implications for teacher educators, encouraging programs to

rank task difficulty, complexity and frustration of field placements for student-teachers.

Experienced and Veteran Teachers. Throughout their careers, practicing teachers must strive to maintain a “competent teacher” identity while continuing to serve their students. This can be challenging particularly in light of the increasing complexity of the teaching task (Woolfolk Hoy, Davis, & Pape, 2005). Some scholars argue that teachers with higher sense of efficacy may be more prone to experience burnout because they tend to set higher standards and expectations (Fives et al., 2007). Faced with rapid changes in student populations and reform movements, practicing teachers may feel threatened and, in lieu of seeking professional development to build mastery, may engage in behaviors designed to preserve their sense of self. While it may preserve sense of self, resistance to change may come at the cost of serving important populations of students. For this reason, it is important for administrators to consult teachers prior to and during reform movements to identify the types of professional development experiences necessary for building mastery, carefully monitoring and adjusting the level of arousal, and providing the feedback that persuades teachers they can be successful (Gregoire, 2003). Several studies suggest practicing teachers’ efficacy can be enhanced through participation in action research (Henson, 2001), reviewing lessons with colleagues (Puchner & Taylor, 2006), regular feedback on their goal pursuit (Labone, 2004), and self-reflection that helps identify and interpret mastery experiences while developing self-regulatory skills.

TEACHER EXPECTATIONS

How are teacher expectations related to student achievement? For much of the last part of the 20th century social psychologists emphasized the power of expectations to

create and distort social reality through self-fulfilling prophecies and expectancy-confirming biases, whereas educational psychologists typically emphasized the accuracy of teacher expectations. This entry conveys why 40 years of research on teacher expectations shows that teacher expectations are indeed mostly accurate and that they lead to typically small but occasionally large self-fulfilling prophecies.

TEACHER EXPECTATIONS AND RELATED CONSTRUCTS DEFINED

In studies on *teacher expectations*, the term has referred to everything from predictions to beliefs about current levels of ability and performance, to beliefs about students' *normative* behavior (essentially, cooperativeness, rule-following, etc.). This application of the term has been justified because such perceptions and beliefs are often the foundations for predictions, and, to the extent that they are inaccurate, may also produce *expectancy effects*, a term that refers to either of two related yet very different phenomena.

Two Types of Expectation Effects. First, erroneous expectations may bias or distort the expectancy-holder's judgments, a phenomenon sometimes referred to as *expectancy-confirming bias*, *perceptual bias*, or *confirmatory bias*. Sometimes perceivers' (including teachers') erroneous expectations lead them to judge, evaluate, interpret, or explain targets' (including students') behavior in ways consistent with those expectations. For example, if a teacher overestimates a student's academic competence, that teacher may evaluate the student's performance (on tests, homework, etc.) more positively than the same teacher evaluates identical work produced by a student whose academic competence the teacher underestimates. These types of expectancy biases influence the teacher's judgments about students' learning or achievement, but they do not necessarily influence students' actual learning or achievement.

The second type of expectancy effect is a self-fulfilling prophecy, which occurs when a perceiver's originally false expectation leads to its own actual (not merely perceived) confirmation. A teacher's erroneous expectation leads to its own fulfillment when it leads the teacher to behave differently towards high and low expectancy students, and when those students' achievement changes to confirm the teacher's (originally false, but now true) expectation. Thus, the high expectancy student achieves at higher levels, and the low expectancy student achieves at lower levels than they otherwise would have had the teacher's expectation been accurate.

Expectancy-confirming biases and self-fulfilling prophecies are similar because both involve expectations causing their own confirmation in some sense (which is why both are termed expectancy effects). They differ, however, in that expectancy-confirming biases occur entirely in the mind of the perceiver (or teacher), whereas the confirmation in self-fulfilling prophecy occurs as a result of an actual change in the behavior (or achievement) of the target (or student).

Accuracy. Teacher accuracy refers to correspondence between teachers' beliefs (expectations, perceptions, judgments, etc.) about one or more students and those students' characteristics or accomplishments, if the teachers' beliefs have not caused those characteristics or accomplishments. Accuracy is important for two reasons. First, accuracy constitutes a very different explanation (than bias or self-fulfilling prophecy) for why students may sometimes confirm teachers' expectations. When *expectancy confirmation* results from accuracy, it reflects teachers' expertise and competence, rather than their flaws and weaknesses. Second, accuracy represents a plausible alternative explanation (to self-fulfilling prophecy or bias) for evidence that students confirm teachers' expectations.

THE PYGMALION STUDY

The scientific study of teacher expectations was launched by the classic and controversial Pygmalion study (Rosenthal & Jacobson, 1968). Rosenthal and Jacobson led teachers to believe that some students in their classes were "late bloomers" destined to show dramatic increases in IQ over the school year. In fact, these students had been selected at random. Results showed that, especially in the earlier grade levels, the "late bloomers" gained more in IQ than other students. Teacher expectations created a self-fulfilling prophecy.

Rosenthal and Jacobson's study (1968) received considerable attention in the social sciences and the popular press because it seemed to provide a powerful explanation for the low achievement of so-called disadvantaged students. However, it was also criticized by educational psychologists on conceptual, methodological, and statistical grounds. A controversy over the existence of the phenomenon continued through the 1970s, which included numerous attempts to replicate it in classrooms and other contexts (work settings, job training programs, laboratories, etc.). Consistently, only about one-third of the studies attempting to demonstrate a self-fulfilling prophecy succeeded (Rosenthal & Rubin, 1978). This pattern was often interpreted by critics as demonstrating that the phenomenon did not exist because support was unreliable. It was interpreted by proponents as demonstrating the existence of self-fulfilling prophecies because, if only chance differences were occurring, replications would only succeed about 5% of the time.

This controversy was resolved in 1978 by Rosenthal and Rubin's meta-analysis of the first 345 studies of interpersonal expectancy effects, which conclusively demonstrated the existence of self-fulfilling prophecies. The overall expectancy effect size was equal to a correlation of about .30 between teacher expectations and student achievement, and the probability of finding the observed expectancy effects, if the phenomenon did not exist, was essentially zero.

REMAINING CONTROVERSY ON TEACHER EXPECTATIONS AND STUDENT INTELLIGENCE

The most stunning claim that emerged from Rosenthal and Jacobson's 1968 study was that teacher expectations have self-fulfilling effects on intelligence. Although IQ test scores often are the best predictors of many important life outcomes, they are also notoriously resistant to change in response to social interventions designed to increase them. In this context, the claim that teacher expectations influence IQ was extremely important, controversial, and difficult (for some) to believe.

Unfortunately, the original Pygmalion study included some results that some researchers found difficult to believe. Although the methodological and statistical issues were numerous, one particular finding was especially problematic. There were five "bloomers" with wild IQ score gains: 17 110, 18 122, 133 202, 111 208, and 113 211. If one simply excluded these five bizarre gains, the difference between the bloomers and the controls evaporated.

Thus, the claim that the Pygmalion study showed that teacher expectations can have self-fulfilling effects on student intelligence was not universally accepted. Unfortunately, the subsequent evidence was also unclear on this issue, with some reviews concluding that the effect of teacher expectations on student intelligence averages near zero, and others concluding that such effects are small, but above zero. The fairest conclusion that can be reached as of 2008, therefore, may be that, if teacher expectations do have an effect on student intelligence, it is typically quite small.

NATURALLY OCCURRING VERSUS EXPERIMENTALLY INDUCED TEACHER EXPECTATIONS

A limitation of the original Pygmalion study and many follow up experiments was that researchers intentionally misled teachers into believing that some students were likely to show dramatic achievement gains. In general, however, teachers do not develop expectations based on falsified information. Thus, some researchers examined whether self-fulfilling prophecies also occurred when teachers developed their expectations naturally, without intervention by experimenters.

Identifying causal effects of teacher expectations is much more difficult in nonexperimental research than in experimental research. In nonexperimental research any particular correlation between teacher expectations and student achievement might occur because teacher expectations caused student achievement (self-fulfilling prophecy), student achievement caused teacher expectations, or some other variable or variables caused them both.

To address this issue, most naturalistic studies took two precautions. First, they used a longitudinal (over time) design, which takes advantage of the fact that the future cannot possibly cause the past. This rules out one possible causal direction. If teacher expectations are measured early in the year, and student achievement late in the year, that student achievement cannot have caused those teacher expectations. Second, naturalistic studies also typically statistically controlled for many of the most plausible predictors of teacher expectations and student future achievement, including student past achievement and demographics, and, sometimes, student self-concept and motivation. If teacher expectations early in the year predict student achievement late in the year, after controlling for all these variables, many third-variable explanations can be eliminated.

The naturalistic research found consistent evidence of self-fulfilling prophecy. In most studies, teacher expectations early in the year predicted student achievement late in the year, even after controlling for student prior achievement, demographics, motivation, and self-concept. The self-fulfilling prophecy effect sizes in such studies was typically about .1 to .2 (in terms of standardized regression coefficients relating teacher expectations to student achievement). Although statistically significant, these effects were consistently lower than found in Rosenthal and Rubin's 1978 meta-analysis of the experiments. Why might this be?

The most likely explanation was that under naturally occurring conditions, teachers' expectations may often be accurate. Indeed, nearly all naturalistic studies of teacher expectations find: 1) student past achievement has large effects on teachers' expectations; and 2) teacher expectations predict (correlate with) student future achievement much more highly than they cause student achievement. These findings are extremely important because they reflect two types of accuracy. The first shows that teacher impression accuracy is high (*impression accuracy* is the extent to which teachers' expectations correspond with students' current characteristics or achievement). The second shows that teacher predictive accuracy is high (*predictive accuracy* is the extent to which teacher expectations predict but do not cause student achievement). Overall, the naturalistic research has shown that about two-thirds to three-fourths of the reason teacher expectations predict student achievement is that those expectations are accurate, and that

one-fourth to one-third of the reason they predict student achievement is that they create self-fulfilling prophecies.

The naturalistic research has also consistently found that teacher expectations predict student grades more strongly than they predict standardized test scores (even after controlling for prior grades, achievement, and demographics). Because teachers assign grades but not standardized test scores, this result most likely reflects expectancy-confirmation bias—teacher expectations biasing their evaluations of students, rather than influencing students' objective achievement. Both bias and self-fulfilling prophecy can and often do occur for grades, so that their effects are cumulative. Thus, expectancy effects (both bias and self-fulfilling prophecy) for grades often account for about half of the reason teacher expectations early in the year predict student grades (the remaining half being accuracy).

BASES OF TEACHER EXPECTATIONS

Teacher expectations are primarily based on student prior achievement and grades, which helps account for their relatively high levels of predictive accuracy. Because of the obvious social implications, both experimental and nonexperimental research has been concerned with whether teacher expectations are also based on social stereotypes. Again, the results partially diverge. In experimental studies, the most common methodology has been to provide teachers with little or ambiguous information about students from different groups (e.g., boys/girls, African Americans/Whites, etc.), and to assess whether teachers hold higher expectations for students from one group. They often do.

Because in real life, however, groups often do differ in average levels of achievement, such results do not necessarily show that stereotypes cause inaccuracy in teacher expectations. This issue, however, has also been addressed in naturalistic research, which has examined the extent to which student demographics predict teacher expectations, even after controlling for students' actual differences in achievement. Such research most often finds little or no effect of student demographic characteristics, meaning that, when teachers do perceive demographic differences there usually are corresponding bona fide demographic differences. The most notable exception seems to involve student gender and teacher perceptions of effort. Teachers routinely assume that girls try harder at school than do boys, even though there is little evidence that they actually do. Because there is good evidence that, in general, girls are more cooperative and obedient than boys, it seems likely that this reflects a halo effect (the presence of one positive trait in a target leads the perceiver to infer other positive attributes).

In contrast to stereotypes, diagnostic labels (ADHD, learning disabled, neurologically impaired, etc.), presumably because they come with greater scientific credibility,

are often powerful sources of teacher expectations. Unfortunately, however, large minorities of students are often mislabeled, and, even when students are appropriately diagnosed, many teachers lack the training to understand how best to maximize such students' learning and achievement. Thus, diagnostic labels are often a culprit in negative self-fulfilling prophecies.

INTERPERSONAL PROCESSES

Much research has addressed how teachers act on their expectations in such a manner as to produce a self-fulfilling prophecy. This research has shown that teachers hold high expectancy students to higher standards of performance and, at the same time, provide a warmer and more supportive environment to them. Differential treatment can lead to self-fulfilling prophecies through either or both of two general routes. High standards means providing high expectancy students with more opportunities to master difficult material. When coupled with the support for doing so, highs may simply learn more material more quickly. In addition, however, differential treatment also may indirectly affect achievement, by enhancing or undermining student motivation. High standards and emotional support are likely to increase students' psychological investment in school, intrinsic motivation, and self-expectations, all of which have well-established beneficial effects on achievement (and, of course, low standards and a cold emotional environment are likely to be demotivating).

MODERATING CONDITIONS

Research has also examined moderators of self-fulfilling prophecies—the conditions under which self-fulfilling prophecies are stronger or weaker. This research has shown that self-fulfilling prophecies are stronger under the following conditions:

When experimental studies manipulate teachers' expectations early rather than late in the year. It is much harder to mislead teachers later in the year, after they have gotten to know their students.

In first, second, and seventh grades, a result that suggests that it is not younger children per se who are more vulnerable, but children who enter new and unfamiliar situations (seventh grade was the first grade of junior high school in many of the studies).

Among teachers high in dogmatism or cognitive rigidity. Even inaccurate expectations will not lead to self-fulfilling prophecies if teachers readily correct their expectations with new information. Teachers high in dogmatism or cognitive rigidity are unlikely to do so.

Among students with some sort of perceived difference from the majority. Some of the largest self-fulfilling prophecy effects ever obtained have been found to occur among some minority students, those from lower social class backgrounds, and those with histories of low achievement.

Many early researchers speculated that negative expectancy effects (those that undermine student achievement) were also more powerful than positive ones (those that enhance student achievement). The evidence regarding this issue, however, is quite mixed, with some studies showing that positive teacher expectations have more powerful self-fulfilling effects, and others showing that negative teacher expectations have more powerful self-fulfilling effects.

IMPLICATIONS FOR TEACHERS

First, teachers should take considerable comfort from the empirical evidence which, in contrast to some of the more extreme claims, shows that, in general, expectancy effects are small, fragile, and fleeting, rather than large, pervasive, and enduring. Second, any recommendation suggesting that teachers should simply adopt high expectations for all students would be oversimplified, unworkable, and probably dysfunctional. High expectations can work at raising student achievement, but only if they are backed up with the resources and institutional supports to do so.

The most constructive lessons to be learned for teachers from the research are the following:

Teachers should hold expectations flexibly. They might be wrong. The student's label might be wrong. Also, students change.

Teachers should remember that holding high standards without providing a warm environment is merely harsh. A warm environment without high standards is simply feel-good mush. But if teachers can create a combination of high standards with a warm and supportive environment, doing so will benefit all students, not just the high achievers.

High expectations will mean different things for different students. Attaining average performance might be high for one student and low for another. If teachers want to purposely harness self-fulfilling prophecy processes to maximize student achievement, they need to integrate accuracy (a clear sense of students' current levels of skill and learning abilities and styles), with warmth and high standards for future performance in order to develop a clear plan for how those students will maximize their learning and achievement.

TEMPERAMENT

Temperament is a general term referring to individual differences in behavior tendencies that are biologically based, present early in life, and relatively stable across situations and time (Bates & Wachs, 1994; Goldsmith et al., 1987). Individual differences in temperament are evidenced in the unique predispositions students bring to the school setting in terms of activity level, attention span, mood, approach to new experiences, and so on. Many have posited that individual differences in temperament during the early years constitute nascent personality (Caspi, 1998).

Evidence supports both genetic and environmental influences on temperament. Behavior-genetic research studies comparing correlations of temperament characteristics between monozygotic and dizygotic twins indicate significant genetic influences on some temperament characteristics from early childhood through adolescence. Monozygotic twins are much more temperamentally similar to each other than dizygotic twins (Caspi, 1998). Given the evidence supporting the role of genetic factors in temperament, researchers look to physiological, neurological, biochemical, and hormonal variables as the biological mechanisms by which temperament is transmitted across generations (Bates & Wachs, 1994). For example, Werner and colleagues (2007) reported that fetal heart rate activity predicted infant temperament assessed via parental report and behavioral observations at 4 months. With respect to environmental factors, children with difficult temperament are at increased risk of subsequent externalizing behavior

problems when family conflict is present (Guerin et al., 2003).

CONCEPTUALIZATION AND MEASUREMENT OF TEMPERAMENT

Although temperament is an ancient concept (Kagan & Snidman, 2004), a large body of empirical research on temperament in children followed the dissemination of the theoretical perspective developed by Alexander Thomas, Stella Chess, and Herbert Birch (1968). They defined temperament as follows:

Temperament may best be viewed as a general term referring to the how of behavior. It differs from ability, which is concerned with the what and how well of behaving, and from motivation, which seeks to account for why a person does what he is doing. When we refer to temperament, we are concerned with the way in which an individual behaves. (p. 4)

Thomas and colleagues identified nine dimensions of temperament, and these are listed in Table 1. Additionally, they observed three constellations or patterns characterizing young children’s temperament. They labeled the largest temperament pattern, comprising about 40% of their sam-

ple, as “Easy” temperament: regular biological functioning, positive approach to new stimuli, quick adaptation to change, positive mood, and mild/moderate intensity in expression. About 10% exhibited the opposite pattern, labeled “Difficult” temperament. Thomas and Chess labeled the third pattern, seen in about 15% of their sample, as “Slow to Warm Up” temperament. These children’s reactions to new stimuli were more often negative than those of children with “Easy” temperament, but they expressed themselves more mildly than children with “Difficult” temperament. Not all children fit into one of the three categories, however, and most research is based on one or more specific dimensions of temperament displayed in Table 1 rather than the constellations.

Subsequent to the Thomas and Chess model of temperament, other approaches to children’s temperament emerged. Arnold Buss and Robert Plomin viewed temperament as early-appearing inherited personality traits and focused on three temperaments: emotionality, activity, and sociability. Hill Goldsmith and Joseph Campos developed a conceptualization of temperament centering on infant primary emotions, such as fear, anger, sadness, pleasure, and interest, for example. Mary Rothbart and Douglas Derryberry proposed a developmental model defining temperament as constitutional differences in reactivity and self-regulation (Goldsmith et al., 1987). Jerome Kagan and colleagues (Kagan & Snidman, 2004) focused on a single temperament characteristic, children’s initial reaction to unfamiliar events. At the extremes of this continuum are children who respond to unfamiliar stimuli with shyness and restraint (inhibited) and those who are sociable, talkative, and minimally fearful (uninhibited).

The most widely used method to measure temperament in infancy and early childhood is through caretaker (usually maternal) reports on standardized temperament inventories; child, youth, and adult self-report inventories are also available. Inventories for teachers to describe their students’ temperament have also been developed (Keogh, 2003). Inventories offer the advantages of efficiency in assessing a range of temperament characteristics and established reliability and validity, with ratings based on individuals who are well-acquainted with the child over a range of situations and across time. In addition to inventories, a variety of behavioral assessment procedures are available (Goldsmith & Rothbart, 1991). Mechanical (e.g., actometers) and behavioral measures of activity have been employed.

CONSISTENCY OF TEMPERAMENT ACROSS TIME

A growing literature documents the stability of children’s temperament. In the United States, the Fullerton Longitudinal Study in California reported stability on eight of the nine

Temperament dimensions identified by Thomas, Chess, et al.	
Dimension	Description
Activity level	Level, tempo, and frequency of motor behavior
Biological rhythmicity	Regularity of biological functions, such as sleeping, feeding, elimination
Approach/withdrawal	Nature of initial response to new stimuli, such as people, food, toys
Adaptability	Ease with which child responds to new stimuli or changes in situation
Intensity of reaction	Energy level of response, ranging from mild to strong, regardless of whether reaction is positive or negative
Quality of mood	Balance of pleasant, joyful, friendly behavior compared to unpleasant, crying, unfriendly behavior
Persistence/attention span	Continuation of an activity in spite of obstacles and length of time a particular activity is pursued
Distractibility	Effectiveness of external stimuli in altering the direction of ongoing behavior
Threshold of responsiveness	Intensity level of stimulation necessary to evoke a response

Table 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

Thomas and Chess temperament dimensions from ages 2 through 12 years. Additionally, six of the nine dimensions were assessed at ages 14 and 16 years, and they also showed stability from middle childhood (Guerin et al., 2003). Mathiesen and Tambs (1999) reported strong stability of the Buss and Plomin temperament traits in a Norwegian sample followed from 18 through 50 months. Komsuoglu and colleagues (2006) observed significant consistency across infancy and middle childhood in a sample of Finnish children for several temperament dimensions based on the Rothbart framework. In the early 2000s, evidence of stability in inhibited/uninhibited temperament was accumulating (Kagan & Snidman, 2004).

RESEARCH FINDINGS ON TEMPERAMENT AND SCHOOL FUNCTIONING

One question to consider is how these stable, individual differences relate to children's functioning in school. The tasks of school demand not only intellectual ability, but also characteristics such as flexibility and sustained effort (Keogh, 2003). Across the entire span of schooling, temperament characteristics relate to children's ability to successfully negotiate the multiple demands of school, whether in terms of academic achievement, socially appropriate behavior, or relationships.

In elementary school, three primary temperament characteristics relating to accomplishment are activity, distractibility, and persistence (Keogh, 2003). Either high or extremely low levels of activity, high levels of distractibility, and low levels of persistence relate to low levels of academic achievement. Similarly in early adolescence, persistence and distractibility relate to school success (Guerin et al., 2003). Children who can focus on their work and sustain an effort in spite of obstacles and length of time to completion achieve more in the academic realm.

During adolescence and early adulthood the characteristic of persistence, identified as task orientation, again stands out as important in terms of academic success. In the Fullerton Longitudinal Study, task orientation related positively to academic achievement as measured by standardized tests, parent reports, and self-reports. Task orientation related positively to high school GPA and college GPA, over and above socioeconomic status and IQ (Oliver, Guerin, & Gottfried, 2007).

In addition to the intellectual domain, children's temperament relates to classroom behavior as assessed by teachers. Guerin and colleagues found that high levels of persistence and adaptability as well as low levels of activity and distractibility were related to behaving appropriately, learning, and being happy in class (Guerin et al., 2003). Characteristics associated with the "Difficult" temperament constellation relate to children acting out in school, but there are also internalizing behavior

problems related to temperament. Extremely inhibited children lack social competence and have high levels of social anxiety (Martin & Fox, 2006).

The quality of the student-teacher relationship has implications for children's competency and achievement in school. Teachers value certain characteristics such as adaptability, persistence, approach, and positive mood (Keogh, 2003). Thus, the behavior of some students with high activity levels, high distractibility, and low levels of persistence, can be misattributed by teachers as non-compliance and problem behavior. As evidence of the way in which temperament characteristics relate to child-teacher relationships, Guerin and colleagues found that children who are high in activity, low in adaptability, high in intensity, negative in mood, less persistent, and more distractible have greater levels of negative interaction and conflict with their teachers.

APPLYING TEMPERAMENT CONCEPTS IN SCHOOL

Given accumulating evidence that temperament characteristics show long-term stability and that individual differences in temperament relate to children's educational outcomes, numerous temperament researchers and clinicians have provided specific recommendations on using temperament research and theory in the classroom. Indeed, Rothbart and Jones (1998) advocate that college and university teacher-training programs include preparation on both children's temperament characteristics as well as their cognitive-processing capacities. A central tenet of the Thomas and Chess conceptualization of temperament is that development will be optimized when the environment and expectations experienced by children are consonant with their capacities and style of behaving ("goodness of fit"). Because individual children experience the same environment in unique ways, information on children's temperamental patterns could be used to modify classroom management techniques to be more in line with the children's style of behavior and reactivity (Rothbart & Jones, 1998). In addition, recognizing individual differences in temperament helps teachers to anticipate times or situations in which problems are most likely to occur (e.g., in transition periods) with the aim of planning techniques to alleviate or manage the stress of these times (Keogh, 2003). Sources providing specific suggestions to improve the goodness of fit between children's temperament and their classroom experience include Keogh (2003), Kristal (2005), and Rothbart and Jones (1998).

TEST ANXIETY

SEE *Evaluation (Test) Anxiety*.

TEST TAKING SKILLS

In a seminal article, Millman, Bishop, and Ebel (1965) defined test wiseness as “a subject’s capacity to utilize the characteristics and formats of the test and/or the test taking

situation to receive a high score” (p. 707). The construct was first described in 1951 by Robert Thorndike, who considered its effect on test reliability. Test wiseness is generally thought to include an awareness of the process of test taking and knowledge of a number of individual test-taking skills that can be applied to a number of different testing formats to maximize test scores. Specific test-taking skills include using time wisely, answering all items, using effective guessing strategies, eliminating choices known to be incorrect, and making use of specific cues imbedded within individual test items. It has been suggested that there is individual variability in test wiseness, in that test-wise individuals have an advantage over individuals similar in knowledge or ability but lacking in test wiseness.

EFFECTIVE SKILLS

Effective test-takers possess a number of skills that go beyond the simple and direct knowledge of the content being tested. These skills include a complete understanding of the purpose(s) of the test, the specific requirements of the test, and any specific constraints placed upon performance, for example, time limits. Test wise test-takers use this awareness in order to employ strategies designed to meet these purposes, requirements, and constraints.

There has been some debate concerning whether test wiseness is a separate and distinct construct. However, specific tests of test-taking skills have been developed, suggesting that such skills do exist and can be described. Test wiseness tests may include items that are answerable only through the use of a test-taking strategy, imbedded within “real” test items. Following is an example of a test-taking skills item:

The Matharah tree is found most often in the following:

- a. arid areas;
- b. dry regions;
- c. rainy climates;
- d. barren locations.

Because the Matharah tree does not exist, test-taking skills must be employed to answer the question. In this case, items *a*, *b*, and *d*, all provide very similar information, and because they cannot all be chosen, the only logical choice is *c*. This strategy is referred to as *similar options*. It has been found that older test takers score higher than younger test takers on tests such as this. Other measures of test wiseness include passage independence tests (where test takers are asked to answer questions about a reading passage without having read the relevant passage), direct interviews (where test takers are asked to describe their thinking process as they answer test

questions), and tests of the test taker's ability to use different test formats (such as separate answer sheets).

Finally, relative deficits in test-taking skills can be inferred by directly training participants in presumed areas of deficit and evaluating whether training results in increased test performance over participants who have not received such training. If this training includes skills only, and not the information being tested, any difference between the two groups can be considered deficits in test-taking skills. Overall, test-taking skills training has realized tangible, but modest effects. However, effects have been more pronounced for older (e.g., upper elementary) students and longer training periods; and for students with mild disabilities (e.g., learning disabilities) and those from lower socio-economic backgrounds. For some groups of test takers, test-taking skills training can make a significant difference in test scores.

TEACHING TEST WISENESS

A variety of procedures are employed to teach test wisdom. Without doubt, the most important strategy for improving test performance is academic preparation, particularly with respect to the specific purpose and anticipated requirements and format of the upcoming test. For example, a multiple choice test format may require broad, general, and shallower knowledge, while an essay format may require more focused, detailed, and elaborated knowledge. Another general strategy is physical preparation, which includes getting sufficient rest and nourishment prior to taking the test. Positive attitudes toward the test are also important and can be improved by setting realistic goals, taking practice tests, understanding the purpose of the particular test, rewarding effort, and understanding of specific test-taking skills.

While taking tests, people should use their time wisely. It is important to use time efficiently on familiar or easier items, and not to waste time on very difficult items unlikely to be answered correctly. Test-wise individuals monitor their time frequently and pace themselves as they take the test. That is, when the testing period is half over, test-takers generally should have completed about half the test. If the test is completed early, the additional time can be spent returning to the more difficult items. Efficient test-takers recognize that, when guessing is not directly penalized, it is important to answer every question.

In any test-taking situation, it is important for test takers to maximize the knowledge they have, even when it is not complete. Many standardized tests as well as classroom tests employ some type of identification format, such as multiple choice, in which test-takers identify a correct response from an array of choices. In these cases, efficient test-takers are careful to think first of a correct

response, then consider all choices before answering. Test-wise individuals are aware that they may not only select the option most likely to be correct, they may also discard items unlikely to be correct, by using elimination strategies. In addition to the similar options strategy discussed previously, test-takers can also, based upon their prior or partial, eliminate responses known not to be correct. For example, even when the answer is not known, if an efficient test-taker can eliminate two of four possible answer choices, the probability of making a correct choice is increased to 50 percent from 25 percent. Over the course of a number of test items, this difference can increase a test score significantly. In other cases, particularly in the case of teacher-made tests, the syntactic or semantic content of the item stem (the "question") may provide a cue to the correct answer choice. This strategy can be enhanced if the test-taker has some partial knowledge of the item content. Test-wise individuals consider carefully choices that use absolutes such as *always* or *never* because few statements allow for no exceptions when choosing their answers.

DIFFERING TEST FORMATS

Some tests include specific formats unique to that particular test. For example, a multiple choice phonics test may require test takers to match sounds in different printed words, or a math test may require test takers to identify which missing information is required to solve a particular problem. Test-takers should practice applications of their knowledge in a variety of different contexts in order to be able to address such formats.

Test formats that require test takers to produce, rather than identify, correct responses also lend themselves to specific test-taking strategies. For example, for short answer or sentence completion items, it is important for test takers to guess if unsure, use partial knowledge when necessary, look for cues in the test item, and make the completed sentence appear logical and consistent. For essay tests, it is generally important to study the question and consider command words (e.g., *discuss*, *compare*, *justify*), note important points, organize thoughts, and write directly to the purpose of the question.

It has been argued that test-taking skills training should be discouraged because it encourages test-takers to outsmart the test, rather than by correctly applying content knowledge. Certainly, some strategies (e.g., the longest or most qualified answer choice will be correct) lend themselves to this criticism. However, in most cases, test-wise individuals employ appropriate strategies in conjunction with their content knowledge to maximize the impact of their knowledge on their test score. To the extent that a test-taker's score should reflect the test taker's level of content knowledge, and not be limited

by relative awareness of test format requirements, test-taking skills training is an important overall component of educational measurement.

THEORIES (AS A FORM OF KNOWLEDGE)

The term *theory* has been historically used to describe forms of disciplinary knowledge. For example, one may speak of Einstein's theory of general relativity or Keynesian economic theory. However, despite or perhaps because of its common usage both in everyday and professional discourse, there is little agreement on just what a theory is. To illustrate, one traditional approach to describing formal disciplinary theories (such as scientific theories) is to think of them as axiomatic systems comprising of natural laws that correspond to empirical regularities in the world (Hempel & Oppenheim, 1948). Within the tradition of scholarship that construes laws as central to theory, there is disagreement about the nature of laws. Some scholars argue that true laws of nature are universal (Armstrong, 1983) while others argue that scientific laws such as Newton's laws are not universal generalizations and should be viewed as causal powers (Cartwright, 1983). More recently, scholars such as Giere have argued that laws serve no useful purpose in the context of scientific theory. Giere (2004) proposes that scientific knowledge is composed of families of models that selectively represent theoretically important features and relationships of things in the world.

THEORIES AS MENTAL REPRESENTATIONS

In the 1980s psychologists and educators who were interested in the nature of mental representation began to draw attention to theory-like properties of mental representations. Although the specific forms of mental representation proposed such as schemas (Rumelhart, 1980) mental models (Gentner & Stevens, 1983; Johnson-Laird, 1983) naïve theories (Carey & Spelke, 1994; Gopnik & Wellman, 1994), and explanatory frameworks (Samarapungavan & Wiers, 1997) vary greatly, they share certain features. These mental representations are molar or larger in scale and scope, and form structures that coordinate a variety of conceptual elements in complex and multifaceted relationships. Such representations serve important explanatory functions, allowing people to organize, predict, and control their experiences of the world. For example, Rumelhart (1980, p. 37) says of schemas, "it is useful to think of a schema as a kind of informal, private, unarticulated theory about the nature of events."

The most explicit analogy between everyday mental representations and theories is drawn in the research on "naïve theories" (Gopnik & Wellman, 1994). "Novice-as-theorist" accounts assume that people are theory generators. Carey and Spelke (1994) have suggested that some conceptual frameworks, such as a naïve physics of object identity and motion, appear in early infancy and may be innate. A key issue for naïve-theoretic accounts of knowledge acquisition has to do with general structural and qualitative properties of naïve belief systems or their degree of "theoreticity." Three important aspects of theories are:

1. *Structure and content*: Theories comprise of a core of interrelated conceptual elements which constitute the explanatory principles for a target domain. The core explanatory principles are not mere empirical generalizations from experience but rather are abstract interpretations of experience. This is reflected in the fact that competing theoretical principles can provide different interpretations for the same body of experiential data. Theories form conceptual topographies. For example, in addition to domain-specific explanatory principles (e.g., natural selection in Darwinian theory), they contain ontological principles (Chi, Slotta, & de Leeuw, 1994) and epistemological principles or beliefs about what the central problems of the domain are, what sorts of data or evidence can be brought to bear in solving these problems, and how the explanatory fit of concepts can be evaluated (Samarapungavan & Wiers, 1997).
2. *Function*: Theories are explanatory devices. The core beliefs of a theory provide causal explanations for the

phenomena it circumscribes. Frameworks also allow for generative predictions;

3. *Corrigibility through epistemic processes*: Theories can be revised as a result of various epistemic processes of knowledge evaluation (Laudan et al., 1986).

The naïve theory approach has borrowed heavily from the work of historian and philosopher of science Thomas Kuhn (1962). Kuhn claimed that major historical changes in scientific theories are accompanied by changes in the explanatory core and boundaries of a discipline, whereby notions of what counts as data and which problems a theory should address change as well. Using similar ideas to explain why students have particular difficulty with the scientific concept of heat, Wiser (1988) suggests that novices have intensive rather than extensive concepts of heat that resemble a historical precursor of the current scientific theory, one in which heat and temperature were not differentiated. Thus, while students correctly predict that on identical burners, a big vessel of water must take longer to boil than a small one, they also make the “wrong” prediction that it would not take more heat to boil water in the big vessel because their concept of heat is intensional. In other words, in the latter situation the students are using the term “heat” in the sense of “temperature” and their predictions are correct with regard to temperature. Wiser concludes that like their historical counterparts, students’ theories of heat are both different from and incommensurate with the expert theory.

Chi and her associates (Chi, Slotta, & de Leeuw, 1994) have proposed an interesting version of the incommensurability argument. They suggest that novices have ontological theories or beliefs about what “kinds” of things exist and what sorts of ontological properties each class or subclass in an ontological hierarchy of “kinds” can possess. Specifically, they propose that peoples’ ontological knowledge is organized into at least three “trees” or taxonomies matter, processes, and mental states. The three trees are defined by mutually exclusive ontological attributes. For example, objects in the category of matter (e.g., water, cars, and dogs) have ontological attributes such as having volume and mass. Similarly, processes have ontological attributes such as “occurring over time.” Chi and colleagues argue that novices have difficulty with the acquisition of scientific concepts because these concepts require a restructuring of their ontologies. For example, while novices typically classify heat as a substance belonging to the ontological tree of matter, scientists see heat as a constraint-based interaction belonging to the ontological tree of processes.

THE DEBATE OVER NOVICE KNOWLEDGE

There is a vast body of research that shows that novice ideas about the natural world differ in conceptual content from those of scientists (Vosniadou & Brewer, 1992, 1994; Wiser, 1988). However, researchers disagree profoundly about the qualitative nature of such lay concepts. For example, based on research about naïve concepts in the domain of motion and force, diSessa and his colleagues (diSessa, 1993; diSessa, Gillespie, & Esterly, 2004) describe novice knowledge as a weakly organized system of beliefs that lacks internal coherence, is unstable over time and problem context, and malleable in the face of anomalous evidence. In a reinterpretation of the work in intuitive physics, diSessa and associates suggest that novices do not have anything like a naïve “theory” of motion or force. According to diSessa (1993), what novices have is a fragmented, unstable, and malleable collection of beliefs which are low-level abstractions of everyday experience. diSessa refers to such beliefs as *p-prims*, short for *phenomenological primitives*. He argues that novice beliefs are unlike scientific theories because they are not constrained by epistemic requirements of coherence or “systematicity.”

Research in several domains suggests that people’s belief systems about some aspects of the natural world are theory-like, at least in some important respects. For example, children and lay adults appear to construct coherent and robust biological constructs based on principles of biological essentialism across a variety of cultures and task contexts (Ahn et al., 2001). Samarapungavan & Wiers, (1997) describe novice beliefs about species and speciation in terms of explanatory frameworks which they describe as a small set of explanatory principles that constrain but do not fully pre-specify the mental models that children construct when presented with novel biological problems about the nature of species and speciation. Part of the evidence for theoreticity comes from the observation that at least some of the core beliefs of novice biological frameworks cannot be induced directly from experience. For example, it is hard to conceive of any direct phenomenal experience that would lead elementary school children to a belief in the spontaneous generation of complex species (Samarapungavan & Wiers, 1997).

Vosniadou and Brewer and colleagues have conducted research on children’s conceptual development in the domain observational astronomy. Their research shows that across a variety of cultures many elementary school children construct scientifically inaccurate but coherent and explanatory mental models of the earth’s shape and the day-night cycle (Samarapungavan, Vosniadou & Brewer, 1996; Vosniadou & Brewer, 1992, Vosniadou,

Skopeliti, & Ikospentaki, 2004). These representations allow people to generate explanations for phenomena such as the seasons, eclipses, and the day/night cycle and to make and evaluate predictions about what will happen in novel scenarios. Additionally, their research shows that initial theory-like representations are corrigible because children revise their mental models over time to integrate new information presented in formal schooling.

Some researchers claim to have obtained empirical results that contradict Vosniadou and Brewer's findings in the domain of astronomy (Nobes et al., 2003). However, Brewer and Vosniadou and colleagues (Brewer, 2008; Vosniadou, Skopeliti, & Ikospentaki, 2004) point out serious methodological flaws in these studies.

THEORIES AS FORMS OF KNOWLEDGE: OPEN QUESTIONS

The debates about the utility of viewing knowledge as being organized in theory-like structures are hard to resolve definitively because of the great variability in the empirical studies on both sides of the issue. For one thing, findings about the degree of coherence and explanatory power in novice knowledge vary by domain. For example, Nakhleh and Samarapungavan (1999) found that elementary school children's ideas about the nature of matter cohered loosely at an ontological level but were not sufficiently coherent in terms of the specific explanations generated for phenomena such as phase transitions to be called explanatory frameworks. It may be that it is easier for people to form coherent knowledge structures in some domains than in others.

A second difficulty in resolving the debates about novice knowledge is the methodological variation in the studies. The studies draw from different populations; vary dramatically in sample size, in the nature and variety of tasks used to elicit data, and the methods for analyzing and aggregating data. One sub-domain in which two studies employed fairly similar methodologies but resulted in radically different conclusions about novice knowledge is that of force and motion. Ioannides and Vosniadou (2002) conducted a cross-sectional study with 105 Greek children (preschoolers through ninth graders) to investigate the development of concepts of force and motion and concluded that children used a small set of coherent constructs to explain phenomena in this domain. diSessa, Gillespie, and Esterly (2004) conducted a quasi-replication of the Ioannides and Vosniadou study with 30 American children across a similar age range. diSessa and colleagues found that the American children invoked a greater number of constructs to explain the phenomena of force and motion, and their use of these constructs varied contextually, showing a lack of coherence.

Although the two studies were relatively similar in the methods used to elicit data, there were nonetheless important differences. One difference was linguistic; the Greek children were tested in the Greek language while the American children were tested in English. Therefore, it is possible that at least some of the questions were not equivalent in translation between the two studies. A second, more important difference was that the American sample was much smaller, less than a quarter of the size of the Greek sample. Given the wide range of ages involved, the subsamples at each age point may have been too small to be truly representative of the population at large. Thirdly and most importantly, although the procedures for data collection were similar in the two studies, the procedures for data analysis were not. Ioannides and Vosniadou (2002) scored children's explanations of their initial answers to each question while diSessa, Gillespie, and Esterly (2004) noted that they were unable to score children's explanations. Thus, despite the similarities in data collection procedures, the actual data set that was analyzed across the two studies was likely to be quite different.

Differences of the kind described above make it hard to render definitive judgments about the utility of regarding lay or everyday representations of the world as theory-like. In general, even if people represent some aspects of the natural world in theory-like ways, it would be implausible to suggest that all knowledge is organized in theories. Even highly regarded scientists such as Charles Darwin, Albert Einstein, or Michael Faraday, probably did not have good theories for every realm of experience. The extent to which knowledge representations are theory-like probably depends on a number of factors including the nature of domain phenomena, the individual's sustained interest and curiosity in the domain, as well as educational and cultural factors. For example, for American children, the dominant cultural model for observational astronomy corresponds to the scientific model. In other domains such as biology, there are often salient competing cultural models to the scientific theory of evolution for important phenomena such as speciation. The availability and salience of such competing cultural models, and the epistemic authority that students accord to various sources of information, are likely to affect both the content and the quality of students' representations.

Given the diversity of theoretical perspectives and empirical findings described above, it appears that while both children and adults may spontaneously construct theory-like representations of the world in some domains of knowledge, they are unlikely to do so uniformly across domains. Additionally, scientific theories are the products of the public institutions of science and their coherence stems in part from their development and modification under processes of rigorous evaluation and critique by the community of scientific practice. In contrast, individual

knowledge representations used in everyday life are rarely subjected to such scrutiny and evaluation. Consequently, when compared with their scientific counterparts, naïve theories are invariably likely to be far less cohesive and consistent.

THEORIES OF INTELLIGENCE

Students' theories of intelligence are their beliefs about the nature and workings of their intellect. Some students believe that their intelligence is a fixed trait—that they have been given a certain amount of intelligence and that is that. This is called an *entity* theory of intelligence, and students with this view become very concerned with how much intelligence they have. Other students believe that their intelligence is a quality they can develop through their effort and education. This is called an *incremental* theory of intelligence, and students with this view are more focused on learning and becoming smarter. Each theory affects not only students' motivation to learn but also their success in learning and their achievement in school.

HISTORY OF THE CONCEPT

Research on theories of intelligence grew out of the study of students' achievement goals (Dweck, 2000). Research had found that some students were strongly oriented toward validating their ability (they pursued *performance goals*), whereas other students were oriented toward learning in the same situation (they pursued *learning* or *mastery* goals). This raised the question: What determined which goals students would favor? Research by Carol Dweck with Mary Bandura and later with Ellen Leggett, Ying-Yi Hong, and C.Y. Chiu (see Dweck, 2006) showed that students' theories of intelligence predicted which goals they would tend to pursue. Students who held a fixed (entity) view of intelligence tended to pursue performance goals in an attempt to document their ability (or in an attempt to avoid a negative judgment of their

ability), whereas students who held a malleable (or incremental) view of their intelligence tended to pursue learning goals in an attempt to develop their ability (e.g., Dweck & Leggett, 1988).

As this work developed, it was shown that this concept applies to a wide range of abilities, including athletic ability and social skills. Individuals can have theories about the fixedness or malleability of many different abilities, and their theories will predict their goals and motivation in these different domains.

More and more research from cognitive psychology and neuroscience is supporting the idea that important parts of intelligence can be developed through educational programs and that the brain has far more plasticity throughout life than was previously believed. It is interesting to note that Alfred Binet (1857–1911), the inventor of the IQ test, had a very strong incremental theory. He developed the IQ test, not to measure fixed intelligence but to identify students who were not on course in the public schools in the hopes of developing better curricula for them.

PREVALENCE, STABILITY, GROUP DIFFERENCES, AND DEVELOPMENTAL CHANGES

It is found that about 40% of students endorse an entity theory, about 40% endorse an incremental theory, and about 20% do not indicate a preference for either theory. Students' theories tend to be relatively stable over time (Robins & Pals, 2002), but they can be changed by a workshop or an intervention. It is not consistently found that the endorsement of a particular theory of intelligence differs by a student's past achievement level, gender, race, or ethnicity. However, it is increasingly found that the theories of intelligence may matter more for females or for students in ethnic or racial groups that are subject to negative stereotypes about ability. In these cases, it is found that holding an entity theory makes students more susceptible to the harmful effects of these stereotypes, whereas holding an incremental theory makes students less vulnerable to them (e.g., Good, Aronson, & Inzlicht, 2003). Overall, it is found that holding an incremental theory of intelligence favors the growth of ability over time (see, e.g., Blackwell, Trzesniewski, & Dweck, 2007).

Researchers have detected the impact of children's theories in children as young as 5 years of age (Heyman, Dweck, & Cain, 1992). However, these are not theories of *intelligence* but rather theories about goodness and badness, which are the issues that young children are dealing with. Vulnerable young children tend to believe they are bad when they fail or are criticized, and they believe that badness is a stable trait. In contrast, resilient young children

tend to believe they are still good children when they fail or are criticized, and that badness can be changed.

METHODS AND ASSESSMENT

TOOLS

Students' theories of intelligence are studied in several ways. First, their theories of intelligence can be measured. This is typically done by asking them to disagree or agree (on a six-point scale) with statements such as "You have a certain amount of intelligence, and you really can't do much to change it" (entity theory) or "No matter who you are, you can change your intelligence a lot" (incremental theory) (see Dweck, 2000 for measures). Students' theories of intelligence are then used to predict their motivation or achievement. Measuring students' theories of intelligence works best with children 10 years of age and older.

Students' theories of intelligence can also be induced (temporarily) by exposing them to stories or articles that espouse an entity or incremental theory of intelligence or by telling them that a task measured a fixed ability or an ability that can be developed. It is then found that these induced theories will predict students' motivation and performance.

Finally, students' theories of intelligence can be changed through workshops or interventions. In these cases, students are taught an incremental theory by means of lessons that convey that the brain is like a muscle that gets stronger with use and that every time students work hard and learn new things, the neurons in their brains form new connections. Researchers then follow the students and look for changes in motivation and achievement.

MAJOR FINDINGS

The research shows that each theory of intelligence creates an entire psychological and motivational framework that has widespread effects (Blackwell et al., 2007). First, the theories, as noted earlier, affect students' goals, orienting them toward documenting their intelligence or toward learning. It has been shown that students with an entity theory will pass up important opportunities to learn if there is a danger that they will do poorly or expose a deficiency (e.g., Hong, Chiu, Dweck, Lin, & Wan, 1999). This is true even if it means that they are putting future achievement in jeopardy by passing up such opportunities. Students with an entity theory may also act defensively and conceal or lie about their deficiencies rather than confront and rectify them. For example, they are more likely to engage in self-handicapping (Rhodewalt, 1994). These are strategies that put students' performance at risk (e.g., watching television instead of studying the night before a test), but allow them to preserve their sense of their ability if they fail.

Next, students' theories of intelligence create different attitudes toward effort. Those with an entity theory believe that effort is a sign of low intelligence (Blackwell et al., 2007). They believe that if you have ability you would not need effort. In contrast, students with an incremental theory believe that effort is a good thing, something that helps build abilities. These different beliefs play an important role in dampening the achievement of entity students and enhancing the achievement of incremental students.

The theories of intelligence also influence students' reactions to setbacks. Students with an entity theory believe that failures, even at the beginning of a new course, signify a lack of ability (Blackwell et al., 2007). In line with this, they display a lack of persistence. For example, compared to students with an incremental theory, they report that they would study less after a poor grade in a new subject, that they would try never to take a course in that subject again, and that they would seriously consider cheating on the next test. Thus, when students believe they lack a fixed ability, they do not see good options for bringing about success in the future. Students with an incremental theory believe that school failures reflect more readily on their effort and their study or learning strategies. As a result, they react to challenges and setbacks with persistence. They step up their effort and they seek new learning and strategies.

When students have been tracked over challenging school transitions, researchers have found that those with the incremental theory out-achieve those with the entity theory (Blackwell et al., 2007). Those with an incremental theory also show increasing self-esteem over challenging times, in comparison to those with an entity theory, who show eroding self-esteem (Robins & Pals, 2002).

Finally, as noted above, several studies have sought to change students' theories of intelligence by creating workshops that teach students an incremental theory. After these workshops, students have shown significant increases in their motivation to learn, their grades, and their achievement test scores (Aronson, Fried, & Good, 2002; Blackwell et al., 2007; Good, Aronson, & Inzlicht, 2003).

TEACHERS' THEORIES OF INTELLIGENCE

There is less research available on teachers' theories of intelligence and how they affect students' achievement. However, work by Falko Rheinberg in Germany has shown that when teachers believe they have an impact on their students' intelligence, many students who were previously low achievers blossom in their classes. However, when teachers believe they have no impact on their students' intelligence, students who entered their classes as low achievers tend to remain low achievers.

It is interesting to note that in the famous Rosenthal and Jacobson research on the teacher expectancy effect, teachers were in a sense given an incremental theory of intelligence. They were told that certain students in their class would blossom intellectually that year (not, as commonly believed, that certain students were simply smart). Their results speak to the efficacy of teachers' holding an incremental theory of a student's ability.

Butler (2000) has examined the impact of teachers' theories of intelligence on their judgments of students' intelligence. She gave teachers information about two students, one whose performance increased over 10 tests and one whose performance decreased over 10 tests. Teachers with an incremental theory judged the student with the increasing performance to have higher ability than the one with decreasing performance, but teachers with an entity theory believed the opposite. Incremental teachers were focusing on progress over time as an index of ability, whereas entity teachers judged students by initial performance even if that performance was not maintained over time.

There has also been research on practices that foster an entity and incremental theory of intelligence in children (e.g., Mueller & Dweck, 1998). In experimental studies it has been shown that when adults praise children for their intelligence (*person praise*), as opposed to their effort (*process praise*), it fosters an entity theory of intelligence. Praising children for their intelligence also led them to care more about looking smart than about learning, made them lose confidence in their abilities when a task became difficult, led them to show impaired motivation and performance after difficulty, and led them to lie about their performance afterward. In contrast, praising children for their effort led them to embrace challenges, maintain confidence in the face of difficulty, maintain their motivation, and show enhanced performance after difficulty. Interestingly, the self-esteem movement has advocated praising children's intelligence and talents as a way to build their confidence and motivation. However, this research shows that, instead, praise for intelligence backfires by fostering an entity theory of intelligence with all of its vulnerabilities.

IMPLICATIONS FOR TEACHERS

The research reviewed shows that an incremental theory of intelligence promotes in students a greater desire to learn and enhanced resilience in the face of difficulty. It also predicts better performance on difficult tasks and across challenging school transitions, and it appears to be particularly important for the achievement of students who labor under negative stereotypes. It has been shown that an incremental theory of intelligence can be directly taught to students by teaching about the brain, for

example, by telling them that the brain is a muscle that gets stronger with effort and learning and that every time they apply themselves and learn new things, their brain forms new connections. As discussed above, an incremental theory can also be encouraged by process praise. This would include praising children's effort, challenge-seeking, strategies, or improvement rather than their product, outcome, or ability. These are messages that can be readily incorporated into everyday classroom practices without altering the curriculum and without a great deal of additional time and effort on the part of teachers.

Carol S. Dweck

THEORIES OF LEARNING

Learning is one of the most important activities in which humans engage. It is at the very core of the educational process, although most of what people learn occurs outside of school. For thousands of years, philosophers and psychologists have sought to understand the nature of learning, how it occurs, and how one person can influence the learning of another person through teaching and similar endeavors. Various theories of learning have been suggested, and these theories differ for a variety of reasons. A theory, most simply, is a combination of different factors or variables woven together in an effort to explain whatever the theory is about. In general, theories based on scientific evidence are considered more valid than theories based on opinion or personal experience. In any case, it is wise to be cautious when comparing the appropriateness of different theories.

In addition to formal theories, people hold personal theories, including theories of learning and teaching. Some typical questions such theories might involve are: How does one determine if learning has occurred? What factors determine whether or not learning occurs? Are these factors located in the environment or within the individual?

This entry focuses first on different conceptions and definitions of learning. Next, the evolution of theories and conceptions of learning over the past 100 years is discussed, highlighting some of the advantages and limitations of different theoretical perspectives. Following a discussion of the relationship between theory and practice, examples of different types of learning are presented, and the appropriateness of different theories for different learning situations is pointed out.

CONCEPTIONS OF "LEARNING"

Understanding any theory requires a clear idea of what the theory is trying to explain. When a particular word is used, people usually assume everyone has a common understanding of what the word means. Unfortunately, such is not always the case. In trying to understand the various theories of learning and their implications for education, it is helpful to realize that the term "learning" means different things to different people and is used somewhat differently in different theories. As theories of

learning evolved over the past half-century, definitions of learning shifted from changes that occur in the mind or behavior of an individual to changes in participation in ongoing activities with other individuals to changes in a person's identity within a group (e.g., a change from being a follower to being a leader). Although, most definitions of learning involve a *change* in an individual's knowledge, ability to perform a skill, or participate in an activity with other individuals, there is considerable variation among the theories about the nature of this change.

Further difficulty in understanding similarities and differences among various theories results from the frequently overlooked fact that there are different types of learning. In many cases, the various theories are relevant to different types of learning and are not necessarily incompatible with one another. Rather, they provide different perspectives on the complex phenomena of learning and complement one another in their ability to explain different types of learning situations. Thus, radically different theories are relevant to the classroom by addressing different aspects of classroom learning, and it is wise to avoid comparing apples with oranges. Examples of different types of learning are presented later in this entry.

EVOLVING THEORIES OF LEARNING

The modern psychological study of learning can be dated from the work of Hermann Ebbinghaus (1850–1909), whose well-known study of memory was published in 1885. Other early studies of learning were by Edward L. Thorndike (1874–1949), whose dissertation on problem solving was published in 1898, and Ivan Pavlov (1849–1936), whose research on classical conditioning was begun in 1899 but first published in English in 1927. These theories focused on explaining the behavior of individuals and became known as behavioral theories. These theories use a stimulus-response framework to explain learning and dominated psychology and education for over half a century. Because behavioral theories focus on environmental factors such as reinforcement, feedback, and practice, they conceptualize learning as something that occurs from the outside in.

Behavioral theories provide very good explanations for certain kinds of learning but poor explanations for other types of learning. Operant conditioning, for example, is better than other theories at explaining the rote acquisition of information, the learning of physical and mental skills, and the development of behaviors conducive to a productive classroom (i.e., classroom management). In these situations, the focus is on performing behavioral tasks rather than developing a learner's cognitive structure or understanding. Although classical con-

ditioning frequently is dismissed as irrelevant to human learning (Pavlov's initial research paradigm involved dogs salivating), this type of learning provides by far the best explanation of how and why people, including students, respond emotionally to a wide variety of stimuli and situations. The many types of emotional reactions acquired through classical conditioning include: anger toward or hatred for a particular person or group, phobias to a particular subject area or to school itself, and infatuation with another person. However, they are very poor at explaining how individuals come to understand complex ideas and phenomena.

But environmental factors are not the only ones that influence learning. Serious consideration of other perspectives began to enter mainstream psychological thinking about learning during the 1960s. For example, people clearly learn by observing others, and a learner's belief about his or her ability to perform a task (i.e., self-efficacy) plays an important role in their learning. In 1963 Albert Bandura and R. H. Walters published the first formal statement of social-learning theory in their book, *Social Learning and Personality Development*. Social-learning theory has clear roots in behavioral theory but differs from these theories in significant ways. During the 1980s the theory became known as social-cognitive theory. Although essentially the same theory, the new name more accurately reflects the cognitive features of the theory and aids in differentiating it from behavioral theories of learning.

During the 1970s and 1980s conceptions and definitions of learning began to change dramatically. Behavioral theories gave way to cognitive theories that focused on mental activities and the understanding of complex material. An information-processing metaphor replaced the stimulus-response framework of behavioral theories. These theories emphasized that learning occurred from the inside out rather than from the outside in. During the late 1970s John Flavell and Ann Brown each began to study metacognition—the learners' awareness of their own learning, an ability to reflect on their own thinking, and the capacity to monitor and manage their learning. During the mid 1980s the study of self-regulated learning began to emerge (see Zimmerman & Schunk, 2001).

Then, especially during the later 1980s and the 1990s, these cognitive theories were challenged by theories that emphasized the importance of social interactions and the sociocultural context of learning. The work of the Russian psychologist Lev Vygotsky (1896–1934) first became available in North America and along with the work of anthropologists such as Jean Lave began to have a major influence on theories of learning. Individuals were seen as initially participating in peripheral activities of a group (known as legitimate peripheral participation)

before becoming fully integrated into group activities. Apprenticeship became a metaphor for the way people learn in natural settings. The notion that people learn by observing others, first articulated in social-cognitive theory, was expanded in a new context.

Traditionally, learning has been viewed as something that occurs within an individual. Individuals may participate and learn in groups, but it is the individual person that learns. With few exceptions, the educational systems in Europe and North America have adopted this perspective, if not entirely with regard to instructional practices, certainly in the evaluation of student performance and the assignment of grades. Many psychologists and educators currently consider learning to be a phenomenon that is distributed among several individuals and/or environmental affordances (such as calculators, computers, and textbooks) or situated (existing or occurring) within a “community of practice” (or community of learners). Both a social and a material dimension are involved in this distribution (Pea, 1993). For example, a student may use a calculator to help learn how to solve a three-digit multiplication problem (the material dimension) and/or work with another student to understand the proper procedures to follow (the social dimension). In either case, the student is not learning totally on his or her own but is taking advantages of resources (affordances) available in the environment. If the student is not able to solve a subsequent problem without the aid of the calculator or another student, then it is possible to see the distributed nature of learning. In such situations, participation or activity rather than acquisition becomes the defining metaphor (Greeno, 2006).

The evolution from behavioral to social to distributed to situated theories of learning was accompanied by new conceptions of knowledge (for a good discussion of these changes, see Schraw, 2006). Traditional theories conceive of knowledge as a commodity capable of being transmitted, more or less intact, from one individual to another. According to these theories, knowledge is something an individual acquires; when a student successfully learns it, he or she can reproduce the knowledge in its original form. In contrast, more recent theories conceive of knowledge as something each learner constructs or creates afresh rather than something that is assimilated in its preexisting form. According to current theories, truly “objective” knowledge does not exist, although something similar exists in the form of collective knowledge within a particular culture or discipline. Knowledge resides in the community of learners (individuals) that creates it and is distributed among members of the community and the various environmental affordances available to the group. Because each person constructs his or her own understandings, the knowledge they acquire is unique. Communities and cultures are composed of

individuals with common understandings, and these groups provide opportunities for new members (e.g., children) to construct similar knowledge of the world through schools and/or a variety of informal activities.

The 1990s were dubbed “The Decade of the Brain,” and huge advances were made in neuroscience and how the brain relates to human behavior and learning. The study of how the brain relates to learning is in its infancy (for an introduction to some of the issue, see Bransford et al., 2006). An understanding of how the neurophysiology of the brain affects learning and cognition will add greatly to our understanding of human learning and have a large influence on future theories of learning. Nevertheless, a psychological component to these theories will remain critical for learning in educational settings. Education as it is presently understood is based on psychological processes and interactions capable of being influenced by instruction, and it seems likely that psychological interventions will continue to be important for the foreseeable future.

THE RELATIONSHIP BETWEEN THEORY AND PRACTICE

The relationship between theories of learning and educational practices is complicated by several factors. One would think that instructional practices should be based on the best theories of learning available, but this relationship is not as straightforward as one might think. Schools and educational practices are far more likely to be based on philosophical beliefs than on empirical studies and theoretical understanding of learning. Schools are established according to different community and cultural beliefs about the world, the nature of humankind and children, locus of authority, and what should be learned. Schools also differ in their beliefs about teaching and learning, but the philosophical beliefs often come first. Every educational system and instructional program contains a theory of learning, although frequently this theory is implicit and goes unrecognized.

These philosophical and theoretical differences are formidable. Many have endured for centuries, and the debate is unlikely to end anytime soon. For example, the “factory model” of schooling dominated education in the United States for many years. This model is based on production and management procedures successful during the industrial revolution. It stands in sharp contrast to the voices of Henry David Thoreau (1817–1862), John Dewey (1859–1952), and others who advocated discovery, social reform, and freedom as the appropriate means of education. Both perspectives are clearly evident in modern-day discussions of education and instructional practices.

The correspondence between these philosophical perspectives and the various theories of learning is quite apparent. Classroom activities in a traditional classroom, for example, revolve around and are controlled by the teacher, who presents the to-be-learned material and dictates the type of learning activities in which students engage. Students are expected to study the information (via classroom activities and homework) until it is mastered. The knowledge being learned is seen as a commodity being passed from one individual (the teacher) to another (the student).

Very different classrooms emerge from different philosophical perspectives. If one believes, for example, that knowledge is something created afresh by each student, that learning occurs from working on authentic tasks in a social environment, and that the mental activities of the student determines what he or she learns, then the resulting classroom is likely to be one in which students work in groups and/or on projects, discussing how best to solve a problem, or negotiating the meaning of a concept. Once again consistency exists between theoretical beliefs and classroom practices. However, it is not always clear which comes first, for there is evidence that individuals seek out and accept information that confirms their existing beliefs while tending to reject information that would disconfirm those beliefs.

This reality leads to another realization regarding the relationship between theory and practice, namely that the relationship is two-way. A common belief is that knowledge flows from scientific theories to the development of effective practices, that sound theories of learning dictate effective educational practices. Science, however, does not always operate in such a linear fashion. In both the physical and social sciences, ideas often come from observing and questioning things that occur in the real world: “Why did that apple fall from the tree?” (a question asked by Isaac Newton [1643–1727] that led to his discovery of the three laws of motion). Scientific breakthroughs also come from trying to solve a practical problem (Stokes, 1997), such as “what is the best way to teach the concept of photosynthesis?” Established educational practices that teachers have found effective can and should be a source of ideas in developing a viable theory of learning.

A third caveat in understanding the relationship between theory and practice is realizing that the student is more important than the teacher in determining what is learned. This does not mean the teacher is not important; only that it is the students’ perceptions, prior knowledge, and beliefs that determine what and if they learn something approximating the instructional goals of the teacher. The bottom line in the teaching-learning process is the learning activities in which the students engage, not the instructional activities in which the teacher engages.

Modern-day conceptions of learning and teaching recognize that students are active, often proactive, participants in the learning process, even if they appear otherwise. This dynamic nature of the learning process is one reason why instructional interventions that appear the same to the teacher can result in very different student outcomes and why rather different instructional methods can result in very similar outcomes (e.g., Nuthall & Alton-Lee, 1990; Olson, 2004).

DIFFERENT TYPES OF LEARNING

The relationship between theories of learning and educational practices is complicated by the reality that there is more than one type of learning. None of the present theories is capable of explaining learning in all situations, and scholars working within a particular theoretical perspective often ignore or deny the importance of other types of learning and the relevance of other theories for different situations. Nearly every educational setting involves several types of learning, each with its unique importance to the functioning of the classroom.

There is little agreement on how many types of learning actually exist. Nevertheless, it should not be too difficult to identify different types of learning in the following examples: (a) learning to tie a shoelace or necktie, (b) being afraid (fearful in a literal sense) to work in a math class after a lengthy public ridicule by a teacher two years earlier for being unable to explain a problem to the class, (c) understanding and explaining causes of the French and American revolutions, (d) learning to cook by watching one’s father or mother, and (e) negotiating an understanding of “learning” with a person holding a different theoretical perspective. Different theories are good for explaining one example but poor for explaining other examples.

When evaluating the validity or usefulness of different theories, especially from the perspective of the student doing the learning, it is helpful to consider what the person is learning and what is taken as evidence that learning has occurred. Students do not always engage in the type of learning sought by the teacher. For example, a teacher conducts a lesson on the Civil War that includes authentic activities, having students question one another about the war, and finally giving the students a quiz. It would not be at all uncommon for the teacher to conclude that a particular student *understood* what happened at Gettysburg when in reality he or she only *memorized certain facts*.

Theories of learning are efforts to explain how people learn. Different theories are based on different assumptions and are appropriate for explaining some learning situations but not others. Theories of learning can inform teaching and the use of different instructional resources

including technology, but ultimately the learning activities in which the student actually engages (mental, physical, and social) determine what a student learns in the classroom. Classroom learning involves social, emotional, and participatory factors in addition to cognitive ones, and theories of learning need to take these factors into account. Most current theories of learning presuppose that the goal of education is to develop the ability of students to understand the content and to think for themselves, presumptions that are consistent with the majority of modern-day schools.

Thomas J. Shuell

THEORY OF MIND

Theory of mind (ToM) is the intuitive understanding of one’s own and other people’s minds or mental states including thoughts, beliefs, perceptions, knowledge, intentions, desires, and emotions and of how those mental states influence behavior. Sometimes called intuitive psychology, folk psychology, or even mind-reading, ToM is an innate human ability. The understanding that others have mental states different from one’s own makes it possible to infer what others are thinking and to predict their behavior. This ability to recognize one’s own state of mind and those of others is central to human consciousness. The study of ToM and identification of the skills comprising ToM is a rapidly changing field of developmental psychology.

THE THEORY OF TOM

The word *theory* in ToM refers to a person’s tacit belief rather than to *theory* in the scientific sense. However, ToM is similar to a scientific theory in that it enables one to interpret and predict another’s actions by evaluating their thoughts, beliefs, desires, or emotions. ToM also qualifies as a theory in the sense that the representations of reality generated by ToM are not directly observable.

The ability to develop a ToM is a cognitive ability that develops by degrees from infancy through childhood and adolescence on into adulthood. It forms a basis for a child’s acquisition of language and the development of appropriate social behavior and skills. ToM includes the ability to understand that the representations generated in one’s mind do not necessarily reflect the real world and that other people may hold different representations. Empathy—the ability to understand another person’s perceptions on a deep level without reference to one’s own perceptions—may be a culminating feature of ToM development.

ToM is involved in all aspects of daily living and social interactions. It underlies learning and teaching and the ability to follow directions and understand socially based information. ToM skills are essential for working cooperatively. They also underlie the ability to manipulate and deceive others. A lack of ToM skills is considered by many to be a core deficit in autism, and studies of autism have promoted research on the development and complex functioning of ToM.

As a basic component of human consciousness ToM has roots in philosophy, particularly in the groundwork for a science of the mind laid down by René Descartes (1596–1650). The Swiss psychologist Jean Piaget (1896–1980) suggested that before the age of 3 or 4 egocentrism prevents children from understanding that other people’s thoughts and viewpoints may differ from their own. In 1978 Nicholas Humphrey proposed that introspective

consciousness has a specific function; it enables social animals to predict each other's behavior. Being aware of the effects of emotions on one's own behavior enables humans to predict the reactions of others to those same emotions.

FALSE BELIEF

In 1978 David Premack and Guy Woodruff coined the term *theory of mind* as it is now used in developmental psychology. They argued that chimpanzees and perhaps other nonhuman primates could understand the intentions of others and therefore possessed ToM. Although that issue remains controversial, Premack and Woodruff's work was an inspiration for psychologists studying normal and abnormal child development.

In 1983 Josef Perner and Heinz Wimmer applied Premack and Woodruff's false-belief test to children using an "unexpected location" task. In one version of this test a puppet named Maxi puts a chocolate in the cupboard and leaves the scene. The experimenter moves the chocolate to a new location and asks the child where Maxi will look for it. In another version called the "Sally-Anne" task, Sally and Anne put a marble in a box. Sally leaves and Anne takes the marble out and puts it in a different box. Up until about the age of 4 most children ascribe their own beliefs to Maxi and Sally and tell the experimenter that Maxi or Sally will look for the chocolate or marble in its new location. However, older children understand that Maxi will look for the chocolate where he last saw it in the cupboard, and Sally will look in the first box. The task requires that children understand that other people's beliefs may differ from their own and then predict how those people will react based on their differing beliefs.

Over the years many permutations of the false-belief test have been developed to ensure that it does not require advanced language skills. In the "unexpected contents" or "Smarties" task a child opens a candy box expecting to find a candy called Smarties and finds pencils instead. Until the age of 3 or 4 children assume that someone else will expect to find pencils in the candy box. Furthermore, children claim that they expected to find pencils when they first opened the box, a phenomenon called hindsight bias. The ability to pass the false-belief test is seen as a major milestone in the development of ToM in young children.

TOM IN INFANTS AND TODDLERS

Although children clearly begin to develop ToM at an earlier age than Piaget thought, researchers disagree as to which behaviors indicate a developing ToM in children younger than 3, and it has been very difficult to assess ToM in preverbal children. Some researchers argue that mimicking by infants is indicative of a developing ToM.

Infants under 1 year expect hands and objects to move in ways that are goal-oriented. Between 6 and 12 months infants develop "joint attention" looking in the direction of someone else's gaze. Between 12 and 18 months babies will look in the direction that someone is pointing, rather than at the person's finger, and will themselves point to draw someone's attention to something. In 2000 Charman and colleagues found that children who showed the highest rates of joint attention at 20 months scored the highest on ToM tests at 44 months.

Some researchers argue that as early as 14 months babies can understand intentional behavior and therefore understand that other people are intentional and mental beings. An 18-month-old who watches an adult try unsuccessfully to hang a loop on a hook will imitate the intended rather than the failed action, even though the baby has only seen the failed action. Toddlers begin to recognize that other people have desires and likes and dislikes that are different from their own. For example, a child can predict that another child who wants a cookie will go to the cookie jar. Two-year-olds understand and use words for their senses and their wants. They engage in pretend play and learn to distinguish between physical and mental events such as a real versus an imaginary playmate.

Three-year-olds begin to understand that other people's minds are distinct from their own but cannot yet clearly distinguish between what they know and what others know. Nevertheless, 3-year-olds have a fairly well-developed ToM. Most 3-year-olds can talk about mental states using words such as *think*, *know*, and *remember*. They can distinguish mental states such as dreams. They also understand that perception can lead to knowledge: Someone who looks inside a box will know what is in it, but someone who cannot see inside the box will not know.

TOM IN PRESCHOOLERS

At about age 4 children recognize that other people have minds and that their minds may hold different information. They also recognize that appearances may be deceptive and can mislead. The appearance-reality (A-R) task is used to assess a child's ability to distinguish between reality and representation. A child is given a sponge that is painted to look like a rock. When asked what the object looks like and what it is really, a 3-year-old will give the same answer to both questions—either a rock or a sponge. In contrast, a 4-year-old will correctly answer that it looks like a rock but is really a sponge. By the age of 5 children can understand that someone who appears happy may actually be sad. However, since the ability to recognize that others may have mistaken beliefs is central to ToM, the false-belief test remains the basic criterion for assessing ToM.

Although it is clear that the abilities to pass false-belief and A-R tasks at about age 4 represent important milestones

in ToM development, the nature of these cognitive shifts is unclear. Simulation theory argues that children learn to understand other's beliefs through imagination by imagining themselves in another person's situation. Other scientists believe that this milestone occurs through a process of conceptual change or through the maturing of structures in the brain that facilitate reasoning about the minds of others. Many psychologists believe that failure on false-belief and other ToM tasks is due to children's immature executive functioning.

Although understanding false belief is universal in normal children over the age of 5, a number of factors appear to affect the exact age at which the skill is acquired. Success on false-belief tests correlates with short-term memory ability. Children with larger vocabularies and those from larger families pass false-belief tests at earlier ages. However, attempts to teach younger children about false-belief have been unsuccessful; the children may show improvement on the specific task that is taught, but not on other false-belief tasks.

ToM development in young children is strongly correlated with language ability. Bilingual preschoolers have increased understanding of both mental and non-mental representations. The acquisition of ToM is delayed in children with some specific language impairments. Both language and ToM skills predict later metamemory knowledge and beliefs about one's own memory and metacognition knowledge and beliefs about one's own cognitive processes.

ToM development appears to be advanced in children with older siblings, in children who participate in early pretend play, and in children whose families talk about mental states. Activities that seem to promote the development of ToM skills include:

- Pretend play and role playing
- Talking about past events
- Reading stories
- Discussing situations such as misunderstandings, teasing, and forgetfulness
- Imagining
- Discussing opinions and perspectives

Deaf children of deaf parents who are exposed to American Sign Language from birth perform similarly to hearing children on ToM tests. However, deaf children with hearing parents are significantly delayed in ToM development. A 2002 study by Schick and colleagues found that certain language skills of deaf children correlated with their ToM skills. For example, a deaf child who could understand the sentence "He thought his cake was in the cupboard" was more likely to pass ToM tests.

It has been suggested that deaf children undergo normal ToM development but lack the language necessary to understand the stories that are generally used in ToM tests.

TOM IN SCHOOL AGE CHILDREN

By age 6 children can pass second-order false-belief tests. In contrast to first-order belief tests (Sally believes the marble is in the first box when it is really in the second), second-order tests require a child to understand that Sally thinks Mary thinks the marble is in the first box, but both Sally and Mary are wrong. By the age of 6 children have acquired another ToM skill—the ability to deceive others. In a 2007 study Talwar and colleagues found that among elementary-school children the ability to maintain consistency between an initial lie and subsequent statements increases with age and correlates with the children's scores on second-order false-belief tests.

ToM skills and knowledge about mental states and attitudes increase dramatically throughout childhood. Compared with younger children, 8-year-olds show more skill in first- and second-order false-belief tests involving physical facts and positive and negative emotions and have a much easier time explaining their responses. However, there are far fewer tests for evaluating ToM in children older than 6 and few ToM studies have focused on children older than about 7.

By elementary school children have gone from a state of self-recognition to a state of self-consciousness. At about age 7 they realize that thinking is an ongoing process or stream-of-consciousness, with each thought triggering a new thought. In contrast, preschoolers believe that mental activity starts and stops with each thought. Whereas very young children are unclear about what it means to know something and how they know it, and older preschoolers often insist that they have always known something that they learned just a few minutes ago, with middle childhood comes the realization that knowledge requires adequate information. Furthermore these children are starting to understand that interpretations of knowledge and situations can be influenced by expectations or biases. They are increasingly able to consider other people's points of view. ToM studies have shown that at about age 7 children come to understand that a person's facial expressions and thoughts do not necessarily coincide and they are increasingly able to link physical symptoms with anxiety. Researchers have found that sarcasm, irony, and bluffing are not well understood until about age 8.

Between the third and fifth grades children's understanding of the role of memory develops significantly. Although it has been both assumed and suggested by research that ToM is closely related to episodic

memory—the ability to re-experience past events—recent research has suggested that ToM may function independently of episodic memory. Perner and colleagues reported in 2007 that episodic memory emerges later than false-belief skills, together with the ability to use imagery to solve visual rotation tasks.

A 1999 study by Simon Baron-Cohen and colleagues examined the ability of 7- to 11-year-olds to recognize a faux pas—saying something that is inappropriate or could be misconstrued—such as mistaking a boy for a girl or a customer in a restaurant for a waiter. The researchers found that the ability to recognize a faux pas developed by age 9 and that girls were better at it than boys.

TOM IN THE CLASSROOM

It is likely that ToM skills underlie a child's ability to understand and make up stories and therefore are important for developing reading skills. Astington and Pelletier (1996) have argued that there is a relationship between the degree of ToM development and the ability to learn by instruction and collaboration, and that ToM skills are linked to the development of scientific and critical thinking.

In a 1998 study Perry Klein found that students' skills in predicting or explaining a doll or cartoon character's behavior correlated with their abilities to plan controlled experiments and explain the causes of events. He suggested that first through fifth graders use science strategies that are dependent on their ToM development. Most 6-year-olds understand the concept of evidence, and 8-year-olds can distinguish between ambiguous and unambiguous evidence. Younger children often hold on to prior beliefs despite evidence to the contrary, whereas older children can revise their beliefs. Likewise, younger children manipulate multiple variables when planning science experiments, failing to hold any factor constant, whereas older children and adults understand the concept of testing only one variable at a time and holding the other factors constant.

In school children need to be able to discuss mutual understandings and misunderstandings and their own beliefs and those of others and to make conceptual changes. These activities all require ToM skills. Helping students to reflect on and talk about their thinking may help improve ToM abilities. Teachers report that children with more advanced ToM skills have better social skills. However, advanced ToM skills can also be utilized for antisocial purposes such as bullying.

The development of ToM may be particularly relevant to classroom learning during middle childhood and adolescence. Although all normal children develop ToM skills in basically the same sequence, the pace of ToM development may be different in different cultures, par-

ticularly among older children. This may be a function of the vocabularies about mental states in different languages or cultural differences in amount of thinking and talking about mental states. There also appear to be gender differences in the development of at least some aspects of ToM. In a 2000 study Bosacki found that 11-year-old girls scored higher than boys on tests of self-understanding and social understanding.

ToM development continues throughout adolescence and into adulthood. However most research with adolescents has focused on metacognition rather than on ToM. Adolescents are well known for a particular type of ToM error—believing that those around them, especially peers, are thinking about them and judging them when there is no evidence that this is the case.

THE NEUROSCIENCE OF TOM

Brain imaging while performing ToM tasks has suggested the involvement of a patch of neurons above the eyes called the anterior paracingulate cortex. Some researchers believe that this region is responsible for the central ToM task of distinguishing between one's own mind and that of another person. The frontal cortex is known to be important for both ToM and cognitive abilities and this region continues to develop during adolescence. Moriguchi and colleagues (2007) studied 9- to 16-year-olds and found that, as in adults, activation of the medial prefrontal cortex, the bilateral superior temporal sulcus (STS), and the temporal pole adjacent to the amygdala were associated with ToM, and that during late childhood and adolescence ToM activation of the medial prefrontal cortex switched from the ventral side to the dorsal. Researchers have found that the left medial prefrontal cortex is strongly activated when normal subjects read a story that requires understanding the mental states of characters, whereas this region is not activated when autistic subjects read the same story. The STS senses biological motion. It is activated by a moving hand but not a moving car and is particularly sensitive to eye and lip movements. The temporal pole is crucial for recalling memories. The amygdala, which is important for emotion, may also be involved in ToM.

Autism researchers have focused on the hypothesis that autistic children do not undergo normal ToM development. Autistic children who do manage to pass ToM tests usually have far more verbal knowledge than other 3- to 5-year-olds. They also laboriously explain their reasoning, whereas normal young children cannot explain their reasoning, suggesting that the autistic children use a different method to succeed on the test. In Baron-Cohen's 1999 study children with Asperger syndrome or high-functioning autism who passed false-belief tests were nonetheless unable to recognize faux pas or recognized them but

continued to make them. Autistic children also have difficulty understanding and carrying out deception. Studies on autistic individuals have helped distinguish between ToM and cognition since autistics can have exceptional cognitive abilities while lacking ToM skills.

THORNDIKE, E(DWARD) L(EE) 1874–1949

“Whatever exists at all exists in some amount. To know it thoroughly involves knowing its quantity as well as its quality” (Thorndike, 1918, p. 16). This quotation captures the attitude that E. L. Thorndike brought to the study of education. The hallmark of his work was his abiding faith in the quantifiability of all aspects of human experience.

LIFE EVENTS

Edward Lee Thorndike was born in Williamsburg, Massachusetts, on August 31, 1874, to Edward Roberts and Abbie (Ladd) Thorndike. E. R. Thorndike was a Methodist minister who served churches in Maine and Massachusetts. Perhaps in reaction to a strict religious upbringing, throughout his life, E. L. Thorndike favored science over religion.

Upon graduation from Wesleyan University in 1895, Thorndike went to Harvard University to study with William James and begin his psychological studies of learning. He soon moved from Harvard to James McKeen Cattell's lab at Columbia University where he undertook his famous puzzle box studies with cats. After earning his doctorate Thorndike spent a year at Western Reserve University before becoming a member of the founding faculty at Teachers College (TC), Columbia University, in the fall of 1899. He remained at TC until his retirement in 1940, publishing approximately 500

E. L. Thorndike THE LIBRARY OF CONGRESS.

books, monographs and papers. (For a list of publications, see Gates, 1949.)

Thorndike married Elizabeth Moulton on August 29, 1900. They had four children, all of whom earned PhDs. The second son, Robert L., followed in his father's footsteps at Teachers College.

E. L. Thorndike's work was widely recognized within his own lifetime. He was elected president of the American Psychological Association (1912), the American Association for the Advancement of Science (1933), and the Psychometric Society (1936). Cattell ranked him first among American psychologists in a 1921 poll for American Men of Science. Thorndike died of a massive cerebral hemorrhage on August 9, 1949.

THORNDIKE'S RESEARCH AND THEORY

E. L. Thorndike formulated a theory of mental associations called connectionism. He believed that the central nervous system was the basis of all behavior. Learning took place when connections were formed between neurons. The purpose of education was to facilitate the formation of desirable connections.

Thorndike was fascinated with individual differences, trying to measure them, explain them, and use them for prediction. He believed that science could solve human problems, and he applied scientific method to problems of education. Much of his career was spent trying to develop methods to measure individual differences and to use these measurements to make education more efficient and successful.

Thorndike set out to place education on a sound scientific footing. The prevalent educational practice in 1900 was the doctrine of mental discipline. Curriculum was founded on opinion, not evidence. Based on his studies he concluded that education must be conducted in the subject to be learned and tailored to the ability levels of the students. He continued his pursuit of quantification and scientific method in education in one of the first books on psychological and educational measurement (Thorndike, 1904).

In addition to his efforts to make education more efficient and scientifically sound, Thorndike expended considerable effort from 1900 to 1925 in developing measures of intellect. Beginning in 1903, he and his students developed a wide variety of measures of human abilities, culminating in the CAVD, a "test constructed (in 1922 1925) as a sample of what a measuring instrument for a mental ability should be" (Thorndike, 1949, p. v.). The acronym stood for Comprehension, Arithmetic, Vocabulary and Direction following, four of the more important dimensions of intellect in Thorndike's view.

In the 1930s, Thorndike turned his attention to problems of lexicography, and in this work, he revolutionized the way dictionaries were produced. For years he had been keeping records of the frequency of word usage in the English language. He used these counts to determine which words to include in his dictionaries and what the order of definitions should be. He also required that each word be defined only using words that were more frequently used than the word being defined. All modern dictionaries now apply these principles.

E. L. Thorndike's influence on education and psychology is so pervasive that it is hard to detect. He pioneered the scientific study of education and made major contributions to the measurement of human abilities, comparative psychology, and social psychology. The hundreds of students he taught have spread his ideas throughout American education and psychology. Most 21st-century education faculty can trace their intellectual ancestry to him through their mentors. A full biography of E. L. Thorndike is available in Joncich (1968).

TIME ON-TASK

Arguably, the primary goal of schooling is to provide students with a safe and engaging environment and ample opportunities to learn. A large portion of a student's typical school day is allocated towards providing these opportunities. However, once lunch, recess, and passing periods are accounted for, the amount of time teachers allocate for learning is far more than the amount of time students are actually engaged in learning. Martella, Nelson, and Marchand-Martella (2003) report that students only spend about 42% of their school day engaged in learning. Time on-task, also known as engaged time, is the amount of time actually spent learning (Slavin, 2003). It is important to acknowledge that engaged time is more than a behavioral concept; it also encompasses the emotional commitment to academics (VanDeWeghe, 2006). For example, students should demonstrate behaviors such as writing, participating in tasks, reading aloud, reading silently, and asking questions; they should also be attentive, interested, and invested in their learning (Greenwood, Horton, & Utley, 2002; Marks, 2000).

Some research concludes that engaged time is the most important influence on academic achievement (Greenwood et al., 2002; Marks, 2000; Slavin, 2003). According to Greenwood and colleagues (2002) academic engaged time increases through second grade and levels off through fifth grade. Conversely, off-task behavior is stable through second grade, increases momentarily through fourth grade, and then declines through fifth grade. Examples of off-task

behavior include talking out of turn, walking around the class, disturbing peers, and daydreaming. Students who engage to a high degree in off-task behavior "will be unable to respond to academic opportunities or manage subject matter tasks rapidly and accurately" (Greenwood et al., 2002, p. 328). This pattern "can lead to dysfunctional school behavior [which can] ultimately culminate in some students leaving school entirely" (Marks, 2000, p. 155).

Children from specific populations seem to experience lower levels of on-task behavior than others, particularly those with attention-deficit/hyperactivity disorder (ADHD; Brock, 2005). A literature review by Junod, DuPaul, Jitendra, Volpe, and Cleary (2006) reported that children with ADHD typically struggle academically because of their lower rates of academic engagement. More specifically, they reported that these individuals experience higher rates of retention and lower grade point averages, college enrolment, and socioeconomic status. Children with ADHD are typically 2.5 times more likely to engage in off-task behavior, which was suggested by Junod and colleagues to be the most influential variable associated with academic difficulties.

It is important to acknowledge that too much emphasis on academic engagement can have adverse outcomes on learning. An overemphasis on engagement as a teaching strategy can create an environment of mock participation, within which students pretend to be on-task but are not engaged in learning. While mock participation may achieve one's desire for students to stay on task behaviorally, it can negatively impact academic achievement as it lowers students' rate of emotional engagement (Slavin, 2003).

MEASURING ON TASK BEHAVIOR

Direct observation can be used to assess levels of on- and off-task behavior. The observation might be conducted by a teacher, teacher's aid, behavior specialist, or school psychologist. Two considerations essential to obtaining accurate data are that (a) the observation be discrete and conducted in a way that does not alter the natural environment and (b) the behavior being observed must be concrete and measurable (O'Neil et al., 1997).

Two observation techniques often used to assess engaged time are frequency (the number of times a behavior occurs) and duration (the length of time that the behavior is expressed from beginning to end) strategies. For low frequency academic engagement behaviors event or frequency data is the easiest to collect and can be done as instruction occurs. For example, a teacher can tally the number of occurrences of a behavior throughout any given week, day, hour, or minute, and a behavioral rate calculated by dividing the number of occurrences by the duration of the observation. Examples of off-task

behaviors often assessed via frequency data are calling out during instruction, number of worksheets completed, and getting out of one's seat. Duration recordings measure the length of time a behavior occurs. This type of recording is best for behaviors that occur over a period of time and have a clear beginning and ending. It requires the observer to attend to the behavior throughout its duration, typically with a stop watch. Examples of off-task behaviors often assessed via duration data are moderate temper tantrums and aggressive outbursts (Browning-Wright & Gurman, 2001).

Another common strategy for measuring on-task behaviors that occur relatively frequently is momentary interval time sampling. This technique entails dividing the observational period (usually 20 minutes) into equal time intervals (e.g., one minute intervals) and recording what the student is doing at each time interval. When measuring engaged time behaviors are typically coded using one of the following four categories: on-task (O), passively off-task (P), verbally off-task (V), or actively off-task (A). Once the observation is complete, the examined behavior is divided by the number of observation periods to obtain an estimate of on- and off-task behavior. Examples of off-task behaviors often assessed via momentary interval time sampling include talking to peers, walking around the classroom, or tapping a pencil.

BETWEEN AND WITHIN TASK TRANSITIONS

Transitioning from one activity to the next, although essential and inevitable, can negatively impact a student's engagement in academics (Martella et al., 2003). Effective transitions, either between-tasks or within-tasks, can have a positive effect on engaged learning as they increase allocated time and decrease the opportunity for disruptive behavior (Lee, 2006). Between-task transitions are tasks that include moving from one subject to another (e.g., math to reading, lunch to reading, or music to science; Martella et al., 2003). According to Slavin (2003) maintaining smoothness is important in decreasing the amount of time spent between tasks. Poor smoothness between tasks can cause abrupt breaks, possibly increasing disruptive behavior; instruction should be as seamless and sequential as possible. Within-tasks transitions are discrete activities that happen within a given task (e.g., passing out math worksheets during a math lesson or passing back graded papers during silent reading; Martella et al., 2003). Teachers can keep students on-task during within-task transitions by maintaining the momentum during the task. Momentum "refers to the avoidance of interruptions or slowdowns" once an activity has started (Slavin, 2003, p. 372).

In a literature review by Lee (2006), behavior momentum was examined in relation to facilitating between and

within task transitions. It was found that when students are presented with several high-probability requests (i.e., those that evoke a high probability of compliance) prior to a low-probability request (i.e., those that evoke a low probability of compliance), task initiation increased and became more efficient. For example, when transitioning from silent reading to writing, a teacher could ask the students to take out a piece of paper, take out a pencil, and write their name on the paper immediately before asking the students to write about what they read; the momentum generated by positive responses to the high-probability request carried over to the low-probability request. The same idea can be used to facilitate within-task transitions in that several high-probability requests can be woven within low-probability requests to establish and maintain behavior momentum.

To alleviate the negative effects of transitions, teachers should be knowledgeable of strategies to maintain on-task behavior. Examples of such include the following:

- Establish a consistent routine and illustrate such via a visual daily schedule (Brock, 2005).

- Make lessons engaging and use materials that are interesting and motivating (Brock, 2005).

- Reinforce on-task behavior and work completion (Brock, 2005).

- Ensure that challenging lessons include relatively easy tasks (Lee, 2006).

- Provide students with reminders as transitions approach; reminders can become more frequent as the transition approaches.

- To maintain momentum and smoothness, avoid stopping instruction for longer than a minute to deal with missing papers, pencils, or other mild off-task behaviors (Slavin, 2003).

- To decrease the amount of total class time spent transitioning, ask students to make transitions as a group and not individually (Slavin, 2003).

TRANSFER

Can humans benefit from their prior experience when attempting to solve novel problems? Transfer research suggests the complexity within this question. This entry describes the various complexities in studying transfer. First competing definitions of transfer are described, and then the discussion turns to the dimensions along which transfer may occur and the types of evidence that different researchers argue is needed to demonstrate the existence of transfer. Obstacles that prevent some from transferring their experience to new situations are described next, and the interventions that have been undertaken to surmount them. Finally, dominant approaches to studying and conceptualizing transfer are discussed, such as the preparation-for-future-learning view, information processing, and situated cognition approaches.

DEFINING TRANSFER

One definition of transfer is: “the carrying over of an act or way of acting from one performance to another” (Wood-

worth & Schlosberg, 1954, p. 734). Another definition is: “the ability to extend what has been learned in one context to new contexts” (Bransford, Brown, & Cocking, 1999, p. 39). A third definition is: “a situation where information learned at one point in time influences performance on information encountered at a later point in time” (Royer, Mestre, and Dufresne, 2005). The broadest of these conceptions suggests that transfer should be a widespread phenomenon: past learning must affect future performance frequently, and, indeed, formal schooling is predicated on this assumption. However, others disagree. Detterman points out: “Transfer has been one of the most actively studied phenomena in psychology . . . Reviewers are in almost total agreement that little transfer occurs” (1993, p. 8). Detterman goes on to suggest, therefore, that the educational implications of the assumption of transfer are misplaced: “Cognitive psychologists, and other people who should know better, continue to advocate a philosophy of education that is totally lacking in empirical support” (1993, p. 16). One wonders who is correct.

The disparity lies, in part, in what qualifies as successful transfer, both in terms of the extent and nature of the initial learning experience and in terms of the novelty and difficulty of the transfer test. The history of this debate goes back over a century to the debate between two famous early psychologists, Edward L. Thorndike (1874–1949) and Charles Judd (1873–1946), about the implications of their findings. Beginning around 1900, Thorndike and his colleagues reported a series of experiments finding poor or uneven transfer across tasks, despite dependence upon similar operations. For example, after training subjects to estimate the area of certain geometric shapes (e.g., 100 sq. cm rectangles), they did not transfer their learning to solve other problems concerning estimating geometric area, such as estimating the area of other rectangles and triangles (see Thorndike & Woodworth, 1901). By contrast, in Judd’s 1908 experiment, boys throwing darts at a submerged target, adapted better to a change in target depth if they were given an explanation of the principle of optical refraction that made the underwater target appear to be at a different depth.

This disparity in experimental evidence regarding transfer success has continued into the 2000s. For example, Gick and Holyoak (1980) employed an analogical transfer experiment using the classic Dunker tumor radiation problem (how to destroy cancer cells within the body without damaging surrounding flesh by converging on the diseased cells from many directions so as to spread out and dilute the potentially damaging effects of the rays) and an analogous military situation (troops spread over many roads to avoid detonating weight-sensitive mines). They found that if subjects were told to think about the training problem, when tackling the transfer test, transfer was superior. By contrast, Reed, Ernst, and

Banerji (1974) failed to demonstrate transfer on most performance measures, using the missionary-cannibal problem (how to get safely across a river in a limited-capacity boat without having the cannibals in the group ever outnumber the missionaries) and an analogous problem substituting wives and jealous husbands. Judd's underwater target findings suggest that a theoretical understanding of principles may be important for successful transfer, a claim supported by Brown's extensive body of work on transfer which also points to the need to foster theoretical understanding, though not necessarily by explicit instruction (e.g., Brown & Kane, 1988; Brown, 1989). (The above study by Gick and Holyoak also points to the need to foster a connection between the training and transfer materials.)

Given that the world outside of psychology experiments does not generally tell problem solvers which aspects of their experience are likely to be most relevant to current problem-solving situations, it could be argued that spontaneity is a requirement for true transfer and, therefore, that this work shows that such transfer is difficult to obtain. Further, much of the evidence for transfer described above is dismissed by some (e.g., Detterman, 1993) as demonstrating only near transfer, in which the transfer test is so close in some way to the training situation as to be trivial. This viewpoint argues that such near transfer does not count as true transfer because the situations in which society values transfer, such as from school learning to work performance, require far transfer, which is rarely obtained. However, others dispute this gloomy conclusion, claiming that training can enhance general thinking skills, which would constitute far transfer of learning (see, e.g., Perkins & Grotzer, 1997; Halpern, 1998). In sum, as of 2008, "There is little agreement in the scholarly community about the nature of transfer, the extent to which it occurs, and the nature of its underlying mechanisms" (Barnett & Ceci, 2002, p. 612).

DIFFERENT DIMENSIONS ALONG WHICH TRANSFER CAN OCCUR

The conflicting evidence concerning whether transfer occurs can be better understood if the disputed claims are dissected and the findings categorized according to the contextual and content dimensions along which transfer of learning has been assessed. Barnett and Ceci (2002) detailed a taxonomy of 6 context and 3 content dimensions along which transfer might be assessed and along which studies have suggested transfer success may differ, with near transfer (transfer to more similar contexts) generally resulting in easier transfer than far transfer (to more dissimilar contexts). The contextual dimensions include knowledge domain (e.g., physics vs. math), physical context (e.g., school vs. home), temporal context (e.g., in 5 minutes vs.

in a month), functional context (e.g., as an academic exercise vs. a task for earning money), social context (e.g., individual vs. group) and modality (e.g., written vs. verbal).

The content dimensions along which transfer success may vary involve the nature of the skill to be transferred (e.g., rote procedure vs. abstract principle), the performance change measured for this skill (e.g., percentage of correct answers vs. speed of response), and the memory demands of the transfer task used to measure it (e.g., spontaneous recall vs. prompted recognition). For example, as suggested by Gick and Holyoak's 1980 work, discussed earlier, transfer assessed after prompting may be easier to achieve than transfer assessed by spontaneous recall. Transfer may also be more likely when "learning contexts are framed as part of a larger ongoing intellectual conversation in which students are actively involved" (Engle, 2006, p. 451). Engle conducted a detailed case study of fifth graders in a Community of Learners classroom and suggested that future research should take into account not just the content to be transferred but also the framing of the wider learning context. The use of the terms *successful transfer* and *far transfer* without specifying and discriminating between these various dimensions has been the source of much confusion.

OBSTACLES TO SUCCESSFUL TRANSFER

Successful transfer requires encoding and subsequently identifying and retrieving relevant knowledge, followed by application of the knowledge to the transfer problem. Problems can occur at any or all of these stages. For example, knowledge may be adequately encoded but a student may fail to recognize its relevance. Successful near transfer combined with unsuccessful far transfer could be due to either a failure to recognize the relevance of the information, a failure to adapt the knowledge to the new situation, or encoding of such a specific interpretation of the initial learning situation that it is not applicable to the new situation. For example, Schliemann and Nunes (1990) found that school math class learning did not transfer to a fishing problem to which the same mathematical concepts could be applied (e.g., calculating proportions). This failure could be because the math class taught the material in a superficial manner, which did not lead to an understanding of the principles underlying the mathematical routines involved but merely showed the students how to mechanically reproduce a very specific arithmetic procedure. Alternatively, it could be that the relevant knowledge was encoded, but the subjects failed to recognize the relevance of that knowledge to the fishing questions, perhaps because that knowledge was, for them, embedded in their knowledge of the school situation. This kind of situation-specificity was explored by Lave (1988) in her classic work with supermarket shoppers, which found a lack of evidence for

PERSPECTIVES ON TRANSFER

The process of prior knowledge influencing the way students solve a present task is known as *transfer*. The traditional view of transfer is known as *direct application*, where old knowledge is automatically applied to new tasks. So if a student is given the “know how” to perform a mathematical procedure in an algebra class, such skills should transfer to chemistry class if needed. However, transfer fails to happen as often as we expect. Direct application theorists have viewed transfer as a relatively rare phenomenon but believe that transfer is more likely to happen when the new task resembles the original one.

Those who favor *high road transfer* take a different perspective. From this view, transfer occurs when students are made aware that new knowledge or skills are in their “mental toolbox.” In the algebra example, students learning a mathematical procedure might be told by their teacher, “Please keep in mind that this mathematical procedure will be used in your science class today.” Later that day when students are solving a chemistry problem which calls for this procedure, the science teacher might remind them to “think about the skill you learned in math class today.” Proponents of the high road transfer perspective believe that a student’s awareness of how his or her skills can be applied in other situations makes all the difference in whether or not transfer occurs.

These different perspectives have led to different methods for testing the occurrence of transfer, and

subsequently, different conditions under which transfer occurs. Those endorsing high road transfer would say that students must correct their misconceptions through inquiry and discussion with their teacher; giving students a take home message to be generally applied in other domains. Advocates of direct application transfer believe students must practice a skill over and over in similar scenarios, until the behavior becomes second nature. This way, there is little need for deliberation when confronted with a new, yet similar task.

The *situated cognition* offers a both an explanation and a potential solution for past difficulties in demonstrating and explaining transfer. Whereas repetition often may be initially helpful in mastering a given skill, students often maintain a narrow perception concerning when and where the skill should be employed. In other words, a strategy that has worked to solve a problem may only seem applicable in the context in which the student originally learned the strategy. For instance, students in a math class might see a particular algebraic formal as being used only for mathematics, because they never had the opportunity to use it in another context (e.g. science). From a situated cognition perspective, this problem can be aided by advising teachers to present information in various contexts and to switch the activities so that students will grasp the skill while thinking critically, and retaining basic strategies and themes.

DeLeon L. Gray

transfer from school math to shopping; despite knowing how to carry out elementary arithmetical operations on a math test, the same procedures were not used to determine unit prices at the market.

Some efforts to resolve these issues have focused on hypothesizing about the precise components of knowledge encoded in the initial training and mapping them onto the components of the transfer problem. Singley and Anderson’s 1989 production rule approach to modeling computer programming learning is of this type. However, applying such approaches to modeling complex and less well structured learning situations, or those

in which similarities are abstract and less apparent, may be difficult.

Transfer processes may also be affected by motivation, which could influence initial learning, initiation of transfer attempts, spontaneity, and persistence in transfer tasks. Studies have shown that having mastery goals consistently predicts cognitive engagement and, in particular, results in activities such as deep processing and metacognitive strategies or insights into the workings of one’s own cognitive systems (Pugh & Bergin, 2006). However, engagement does not always predict achievement, though this may be because of the kinds of achievement measures used, which may not reflect the deep processing associated with transfer

(Pugh & Bergin, 2006). Performance goals may have damaging effects on engagement and transfer because a focus on avoiding a display of incompetence hampers deep processing and a focus on trying to do well shows mixed results. For example, a study by Bereby-Meyer and Kaplan (2005) found that, for a group of grade-school children, the performance-approach goal condition did not differ from the control condition when the goal was induced before encoding and performed worse than the control when the goal was induced after encoding but prior to the transfer test.

INSTRUCTIONAL INTERVENTIONS THAT PROMOTE TRANSFER

Experimental studies have generally found that learning experiences that promote deep, theoretical understanding are most conducive to transfer to different domains (see Barnett & Ceci, 2002, for a review). Deep understanding can be facilitated by encouraging learners to compare and contrast a variety of examples and by requiring them to explain and justify their decisions. A number of researchers have reached similar conclusions and have investigated ways in which training can promote such understanding. Generally, these approaches focus on getting the learners to engage with the training materials at a deep, structural level. Catrambone and Holyoak (1989) used comparison questions with multiple examples, which improved transfer, for example. Similarly, Cummins (1992) found that inter-problem processing (focus on comparison questions) promoted more transfer than intra-problem processing (focus on specific wording or details). Needham and Begg (1991) encouraged their subjects to fruitfully engage with learning materials by using problem-oriented training (e.g., trying to explain) in contrast to memory-oriented training. However, it is not obvious what deep theoretical understanding really means. Wagner (2006) has suggested that it may not necessarily be more abstract but instead may be “increasingly complex sensitivity to the contextual differences . . . encountered” (p. 4).

Halpern, Hansen, and Riefer (1990) suggested that hard work pays off in their study that enhanced subjects' ability to draw inferences from a studied passage by including far analogies in their training materials, presumably encouraging a focus on deep, structural processing. Their subjects did not derive the same benefit from a near analogy, which the authors suggest may be because they did not have to work as hard to make sense of it. Similarly, Reed and Saavedra (1986) showed that a task involving more concrete and effortful processing, termed the *discovery method* (running a computer simulation with feedback), improved performance more than a passive task (observing a computer-generated graph).

The merits of the discovery method of learning have been the subject of much debate. Chen and Klahr (1999)

studied children's learning of the scientific method, specifically the “control of variables strategy” (the idea that one can figure out whether something is causal by changing it while holding all else the same). They compared training using probing questions with or without direct instruction and found that direct instruction was necessary for learning and transfer. Later, Klahr and Nigam (2004) compared the effectiveness of direct instruction and discovery learning on learning and transfer. They concluded that more children learned from direct instruction, challenging the “widely accepted claim in the science- and mathematics-education community . . . that discovery learning, as opposed to direct instruction, is the best way to get deep and lasting understanding” (p. 661). However, Kuhn (2005, 2006) disputes this conclusion, suggesting that “direct instruction appears to be neither a necessary nor sufficient condition for robust acquisition or for maintenance over time” (2006, p. 384) based on her research. Klahr (2005) disagrees with her interpretation of her findings, instead stating that “they show how difficult it is to achieve long-term transfer with anything less than extremely detailed and direct instruction” (p. 871). Further research is needed to resolve this debate.

PREPARATION FOR FUTURE LEARNING

The constructivist view of learning argues that the challenge is for learners to construct new knowledge for themselves and that one factor which determines their ability to do so is their level of prior knowledge (Bransford et al., 2000). For example, Schwartz and Bransford (1998) demonstrated that preparatory work, such as generating distinctions between contrasting cases in psychological experiments, enhanced future learning from a lecture, as measured by transfer one week later. They proposed a distinction between this preparation-for-future-learning view and a sequestered approach which does not provide access to outside sources of information, suggesting that much classical transfer research is from the latter paradigm and advocating for the former. Sequestered problem solving is inadequate as an assessment of learning because it artificially restricts the problem solver's access to other sources of information which are an integral part of problem solving. Their preparation-for-future-learning view advocates exploration of how past learning prepares the learner for future learning in contrast to the sequestered problem-solving approach. However, learning and transfer could theoretically be assessed in an information-poor or an information-rich environment (sequestered or not), independent of the transfer measure used (problem-solving performance or enhanced future learning).

The broader concept of transfer suggested by the preparation-for-future-learning view fits within the tradition of

studying more generalized outcomes such as the development of practical intelligence (see Sternberg & Kalmar, 1998) and metacognitive and critical thinking skills. As stated by the renowned transfer researcher, the late Ann Brown, “Effective learners operate best when they have insight into their own strengths and weaknesses and access to their own repertoires of strategies for learning. For the past 20 years or so, this type of knowledge and control over thinking has been termed *metacognition*” (Brown, 1997, p. 411). Halpern’s 1998 critical thinking program is an attempt to boost such general reasoning skills: “to promote the learning of transcontextual thinking skills and the awareness of and the ability to direct one’s own thinking and learning” (p. 451). Halpern’s program of instruction builds skills such as verbal reasoning, argument analysis, hypothesis testing, probability, and decision-making. Training also aims to promote transfer by focusing on awareness of which skills to use and providing practice with a broad range of examples, supported by feedback and probing questions. One of the goals is to develop the rich, interconnected knowledge structures the deep understanding that Brown (1989) suggested is important for transfer. In line with this view, the National Research Council’s Committee on the Development of the Science of Learning (Bransford, Brown, & Cocking, 1999) concluded that transfer can be facilitated by training students in metacognitive awareness through activities that encourage introspective awareness and self-monitoring.

DIFFERENT THEORETICAL PERSPECTIVES TREATMENT OF TRANSFER

Some cognitive scientists have studied much more tightly specified learning and transfer processes. Holland and colleagues (1986) described the mechanism of analogical transfer, in terms of four steps: “encoding of the target, selection of a source analog, mapping of the source and target, and transfer of knowledge to the target by generation of new rules” (p. 307). Each step can then be broken down further, for example, encoding involves representing the problem in terms of the initial state, goal state, relevant operators, and path constraints. Singley and Anderson (1989; Anderson 1993) took this information processing approach further and proposed that cognitive skills can be understood in terms of production rules which represent knowledge, which can then be instantiated in, for example, computerized tutors for teaching programming skills.

Such decontextualised approaches have been criticized (see, e.g., Lave, 1988) for neglecting the embeddedness of learning and knowledge in context. Lave has advocated a strong view of this “situated cognition” hypothesis and suggests that learning is inextricably entwined with the context in which it was acquired: “Cognition . . . is distributed

. . . not divided among mind, body, activity and culturally organized settings (which include other actors)” (p. 1). More nuanced interpretations suggest that aspects of context may moderate transferability (Barnett & Ceci, 2002).

Lobato (2003) distinguished between what she called the classical transfer approach and actor-oriented transfer and suggested that the apparent failure to transfer in many traditional experiments was, in fact, a failure on the part of the experimenters to adopt the perspective of the learner. On this view, success or failure on the particular outcome measures the researcher had in mind is immaterial; what matters is how the learners make connections between the new and old situations. This approach often uses case studies as an investigative method, either alone (see, e.g., Lobato & Siebert, 2002) or in conjunction with group data (see, e.g., Dufresne et al., 2005). Lobato (2006) contrasts the classical transfer approach, of using highly controlled experiments and statistical analysis to assess whether particular learning opportunities result in predetermined differences on carefully designed transfer assessments, with her actor-oriented approach, using ethnographic methods to search for effects of prior learning on novel situations. This method increases the likelihood of capturing subtle effects on future performance that may not have been the intended lesson to be learned, but that may nevertheless provide insight into the mechanisms underlying the transfer process and generate hypotheses for further investigations. She emphasizes that generalization involves the construction of relationships rather than simply the reproduction of existing relations.

However, the implication that traditional transfer researchers have ignored the wider effects of prior learning and focused exclusively on a narrow, experimenter-imposed measure of transfer is somewhat misleading. Traditional researchers have often devised multiple assessments of learning outcomes and explored the consequences of many experimental manipulations to capture the richness of the learning and transfer processes, as well as used microgenetic methods to understand the step-by-step processes of learning (see, e.g., Brown & Kane, 1988; Chen & Klahr, 1999).

TRIARCHIC THEORY OF INTELLIGENCE

Webster (1996) defines intelligence as the “capacity for learning, reasoning, understanding, and similar forms of mental activity” (p. 990). This definition implies that intelligence is both multifaceted (i.e., captures many aspects of mental ability) and reflective of differences in capacity, ability, and aptitude among individuals. Yet this definition is not necessarily embraced by all scientists. In fact, there is no consensus on the definition of intelligence among professionals who study it (e.g., psychologists, educators, and computer scientists), and many attempts have been made to define and generate supporting theories about exactly what constitutes intelligence. Among the many theories of

intelligence are those that define intelligence as a cognitive “system.” The overarching assumption of these systemic theories is that intelligence is not a single entity but a multifaceted structure and that traditional definitions of intelligence have been excessively narrow. The quest for theories that reflect the variety of ways in which humans think, learn, and adapt to their environment was initiated in the early 1980s in the United States. Most notable among systemic theories of intelligence is Robert Sternberg’s *Triarchic Theory of Intelligence* (Sternberg, 1996). Other examples are Howard Gardner’s *Theory of Multiple Intelligences* (Gardner, 1993) and the theory of *Emotional Intelligence*, initially presented in the scientific literature by Peter Salovey and Jack Mayer (Salovey & Mayer, 1990) and popularized by Daniel Goleman (Goleman, 1995).

Sternberg’s Triarchic Theory of Intelligence was developed about the same time as Gardner’s Theory of Multiple Intelligences. Rejecting traditionally narrow definitions of intelligence, Sternberg defined intelligence as mental activity central to one’s life in real-world environments; individuals “succeed” in life when they use mental skills to adapt to, select, and shape external environments. Correspondingly, in the late 1990s, Sternberg changed the name of the theory to the *Theory of Successful Intelligence*. As per its original name, the theory comprises three types of intelligence: *analytical* (also referred to as componential); *practical* (also referred to as contextual) and *creative* (also referred to as experiential). *Analytical intelligence* is evoked while analyzing, evaluating, criticizing, reasoning, and judging. *Practical intelligence* is used while implying, implementing, and using. *Creative intelligence* is manifested while discovering, inventing, dealing with novelty, and creating. The theory predicts that “intelligent” people will identify their strengths and weaknesses, make the most of their strengths and compensate for their weaknesses. Individuals are not limited to strength in only one of the three areas; both integrated and uneven profiles of intelligence are possible.

Sternberg’s work on the Theory of Successful Intelligence unfolded in three phases. The first phase was the validation of the fundamental importance of different abilities and the collection of supporting evidence from different cultures and societies. This work took place in a number of countries (e.g., China, India, Jamaica, Kenya, Russia, Taiwan, Tanzania, the United States, and Zambia) and in a variety of settings, both educational and occupational. These studies provided compelling evidence that the focus on traditionally-defined cognitive abilities (i.e., interpreting intelligence through the so-called *general factor* of intelligence, or *g*, as something common to all tests of intelligence) underestimates the importance of practical and creative abilities in human cultures. In one study, for example, Sternberg and his colleagues found that knowledge of herbal medicine among rural Kenyan children was perceived by adults in their communities as equal to or

more indicative of cognitive competence and, thus, as valuable or more highly valued, given the ecological conditions of a relatively isolated African village, than the children’s performance on conventional tests of *g* (such as the Raven Matrices) or their achievement at school. A set of studies has been conducted to investigate implicit theories of intelligence in laypeople around the world. People from different cultures were found to differ widely in their emphasis of what they view as intelligence behavior. For example, even in the United States, people in some cultures, such as Latinos, value and emphasize social functioning facets of intelligence more than other cultures, such as Anglos. Around the globe, people also differ in their taste for when and how intelligence behaviors should be manifested. For example, Taiwanese Chinese appear to value a sensitivity to when one’s intelligence should be shown off and when it should be concealed.

The second phase included studies designed to develop valid and reliable methods to assess analytical, practical, and creative abilities. This domain of research combined multiple efforts to design different instruments that can capture these abilities in both educational and employment settings. As an illustration, Sternberg and his colleagues worked with the U.S. Army to quantify the practical abilities of U.S. officers by capturing, describing, and measuring their “tacit” knowledge of military leadership so that this knowledge could be integrated into the training of military cadets preparing for future leadership roles. Similarly, the theory has been realized in the creation of different assessment instruments. An early version of such an instrument was referred to as The Sternberg Triarchic Abilities Test, or the STAT. The STAT had three subtests, analytical, practical, and creative, and contained items in two formats, multiple choice and essays. The latest generation of this instrument is referred to as the Aurora Battery.

The battery is designed for children in elementary and middle schools and captures their analytical, practical, and creative abilities in the domains of dealing with and manipulating words, numbers, and images (i.e., tapping into verbal, mathematical, and spatial representations). The Aurora Battery contains four components, engaging multiple methods and multiple informants. Specifically, it includes (a) group-administered assessment of abilities, which are captured by multiple-choice, right/wrong responses, and open-ended items; (b) a teacher rating scale; (c) a parent interview; and (d) a portfolio-based observation schedule (i.e., a collection of one-on-one assessments in which children are given a chance to generate specific products in situations modeling real life).

The third phase was designed to apply the Theory of Successful Intelligence to the educational environment. Sternberg and his colleagues completed multiple studies in U.S. schools in a variety of subject matters across

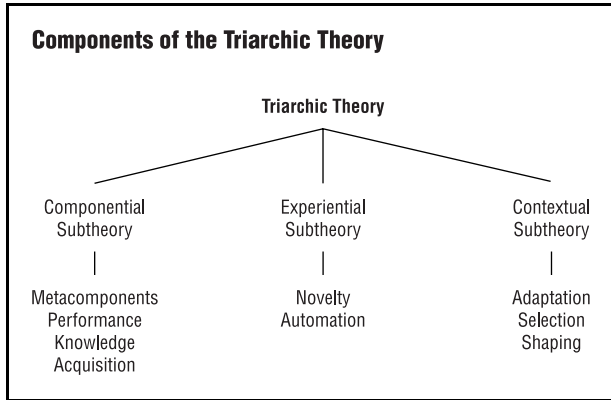

ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

multiple grade levels. The main thrust of this research was to demonstrate the value of multiple pedagogical approaches that ensure that children are taught in ways that challenge and develop their analytical, practical, and creative abilities. Pedagogical intervention studies based on the theory were carried out across different levels of schooling (elementary, middle, and high) and across a number of academic subjects (e.g., mathematics, science, language arts, social studies). In one of the largest studies, a triarchic theory-based curriculum was administered to a few thousand children enrolled in fourth grade in various locations in the United States. The curriculum was developed for language arts, mathematics, and sciences; it was based on the national standards and, prior to implementation, was adapted to specifics of requirements of the various states and districts where it was delivered. The study included three other comparison groups, all with a large number of children: (a) a group of children to whom a traditional (i.e., “treatment-as-usual”) curriculum was delivered; (b) a group of children to whom a curriculum based on modern theories of memory was administered; and (c) a group of children who were taught with a curriculum based on theories of critical thinking. In each case, the study group was followed for approximately six months.

Although the profile of results is complex and variable for each domain of studies, there is a strong indication of an overall advantage of triarchic-based teaching. In general, this and similar studies have demonstrated the benefit of this approach: students not only developed competencies in thinking analytically, creatively, and practically, but also improved their performance on standardized tests. Capitalizing on empirical evidence obtained in his research studies, Sternberg has brought his work on the Theory of Successful Intelligence to a policy level. As the Director of the PACE (Psychology of Abilities, Competencies, and Expertise) Center at Yale Uni-

versity, Sternberg worked with the College Board on developing a triarchic assessment, referred to as the Rainbow Assessment, augmenting the SAT. As Dean of Arts and Sciences at Tufts University, within the framework of the Kaleidoscope Project, he ensured that, in addition to scores on standardized tests, assessments of creative and practical abilities are considered in student admission decisions.

Sternberg’s theories have two main complements in the literature. The first is Howard Gardner’s Theory of Multiple Intelligences. This theory (also referred to as the *MI* theory) was developed at roughly the same time as Sternberg’s theory and also assumes the presence of a number of distinct forms of intelligence. Individuals possess these types of intelligence in varying degrees, which establishes their unique cognitive profiles. Like Sternberg’s, Gardner’s theory is based on the argument that traditional definitions of intelligence do not capture the wide variety of abilities humans display. To support his argument, Gardner analyzed case studies of individuals with unusual talents, such as child prodigies in music or mathematics; reviewed neuropsychological evidence on specialized areas of the brain that process particular types of information; and integrated evolutionary theory and results of psychometric tests.

According to Gardner, there are eight primary forms of intelligence: *linguistic* (manifested in dealing with spoken or written words); *musical* (demonstrated in dealing with rhythm, music and hearing); *logical-mathematical* (invoked while reasoning inductively or deductively and dealing with abstractions and numbers); *spatial* (engaged in vision and spatial judgment); *bodily-kinesthetic* (required for movement and doing); *interpersonal* (needed for interactions with others); *intrapersonal* (manifested in dealing with self) and *naturalistic* (demonstrated in dealing with nature, nurturing, and classification). The addition of a ninth form of intelligence, *existential* (descriptive of the capacity to raise and consider abstract philosophical questions), is still being considered.

Because of its humanistic approach to acknowledging and promoting the value and contributions of each individual student, the theory has been embraced and supported by the educational community around the world. A number of schools and many teachers claim to use this theory as the fundamental framework for their pedagogy. Yet the theory has been widely criticized as well; it has been argued that the theory is based primarily on Gardner’s intuition and observations rather than evidence, that there are limited empirical data to support the evidence, that the separation between the constructs of multiple intelligences and personality types is blurry, that the assumption that all students are gifted in something might lead to intellectual relativism, and that there has been no systematic evaluation of the value of the theory in the classroom.

The second complementary stream of research, focused on the construct often called emotional intelligence, is associated with both Sternberg's theories (through his concept of practical intelligence) and Gardner's theories (through his concept of intrapersonal and interpersonal intelligences). Emotional intelligence is typically referred to as the ability, capacity, or skill to perceive and register, judge and assess, and manage and act on the emotions of self and others; yet there is currently no consensus definition for this term. The roots of the theory are in the use of the term *social intelligence* by American psychologist Edward Thorndike (Thorndike, 1920), who used this term to refer to the skill of getting along with other people. The term *emotional intelligence* is associated with the doctoral work of Wayne Payne (Payne, 1985); the systematic research on the construct definition and measurement is linked to Peter Salovey and Jack Mayer (Salovey & Mayer, 1990), and the popularization of the concept is associated with Daniel Goleman (Goleman, 1995). The field of emotional intelligence is relatively new, and a number of psychologists and educators are now working on the definition, assessment, and predictive power of this concept.

These three theories, although differing in detail, are aimed at diversifying the views and values of different abilities and competencies as they are exhibited by members of today's complex societies. All three theories stress the importance of expanding teaching approaches so that they encompass and target abilities and competencies that are distinct from those that only memorize and accumulate new knowledge. Although all three theories have been applied in the field of education, the Theory of Successful Intelligence appears to have accumulated the largest body of empirical evidence in its support.

Sternberg's theory has three major implications for educational psychology. First, teaching for all types of intelligence is important because students need to capitalize on their strongest abilities at the same time they work to develop the abilities in which they demonstrate weaknesses. Second, students' strongest abilities are directly connected to their most amenable learning styles. Teachers should know the learning preferences of their students and, when possible, capitalize on them. Third, because these variable abilities exist there should be many diverse assessments of school achievement, not only those that focus on traditional analytical abilities.

Sternberg's theory is widely referenced in the psychological and education literature and can be found in virtually any psychology or education textbook. Yet in the realm of practical applications, the theory has been regarded critically. The major points of criticism focus on the difficulties of reliably measuring "unconventional" (e.g., creative and practical) abilities and differentiating them psychometrically from abilities measured by more

conventional tests of intelligence and achievement. These criticisms, however, are not specific to Sternberg's work and are often extended to the work on MI theory and the theory of Emotional Intelligence. Thus, study in the field continues with the goal of developing psychometrically sound assessment instruments suitable for quantifying these abilities, tracking them developmentally, and demonstrating their importance in educational and occupational contexts.

TUTORING

Tutoring refers to an instructional method in which a tutor teaches or guides a tutee about a specific subject matter or for a particular purpose by providing explanations, modeling targeted behaviors, and/or providing prompts and feedback to students' performance. Although one tutor can teach two or three tutees simultaneously, most tutoring involves one tutor teaching one student (thus the term "one-to-one" tutoring). Everyday tutors are often peers and other paraprofessionals with little experience in teaching, although they are knowledgeable about the content domains they teach (Bloom, 1984; Cohen, Kulik & Kulik, 1982). Terms such as *expert* and *novice* tutors are used to differentiate tutors with and without pedagogical expertise. The development of artificial intelligence and information technology has also made it possible for computers to serve as tutors.

EFFECTIVENESS OF TUTORING

One-to-one human tutoring has been shown to be a very effective form of instruction. The average tutored students achieved performance gains about two standard deviations (thus usually referred to as the *2 sigma effect*) above the average students in conventional classrooms with a class size of 30 students (Bloom, 1984). A meta-analysis of school tutoring programs reported superior academic performance of tutored students in 45 of the 52 studies. The average effect size was modest (.4), but it varied from study to study with the largest effect size reaching 2.3 (Cohen et al., 1982).

Tutoring effectiveness varied depending on a number of features of the tutoring program. The effect was larger when mathematics was taught as compared to reading and also when lower level skills were assessed. The effect was also larger in structured tutoring programs and also in programs of shorter durations. However, age difference between the tutor and the tutee did not seem to matter. Providing tutors with pre-training did not increase the effect sizes either (Cohen et al., 1982).

Tutoring produces effects not only on the cognitive level, but also on the affective level. In addition to higher achievement scores, tutored students developed positive attitudes toward the subject matter covered in the instruction. Tutoring also benefits both tutors and tutees. Although the amount of improvement was smaller than that of the tutee's learning, tutors' achievement test scores also improved in 33 out of the 38 studies (Cohen et al., 1982). This effect is often called *learning by teaching* (Bargh & Schul, 1980) or the *tutor learning effect* (Roscoe & Chi, 2007).

WHAT TUTORS DO

The tutoring session is predominantly controlled by tutors. Tutors, not the students, are the ones who set the agenda, introduced the subtopic, and/or proposed problems to solve. Tutors also speak first, take more turns, and make more statements than tutees (Chi, Siler, Jeong, Yamauch, & Hausmann, 2001; Graesser, Person, & Magliano, 1995; McArthur, Stasz, & Zmuidzinas, 1990). Given their dominance of the tutoring session, it is only natural to assume that tutoring is effective because of what tutors do. This leads to the conjecture that tutors would undertake an array of sophisticated pedagogical moves during tutoring. Research on tutoring, however, shows that although certain moves are frequently undertaken by tutors, they rarely undertake other, often more sophisticated pedagogical moves in spite of the conjectures and expectations that they would do so.

Feedback and Explanation. Earlier research on human and computer tutors highlighted the role of tutorial feedback (Anderson, Boyle, & Reiser, 1985; Anderson, Con-

rad, & Corbett, 1989; McArthur et al., 1990; Merrill, Reiser, Merrill, Landes, 1995; Merrill, Reiser, Ranney, & Trafton, 1992). For example, Merrill and colleagues (1995) studied natural human tutoring in computer programming and found that tutors kept the students' problem solving on track by providing ongoing confirmatory feedback and setting new goals. When errors were made, tutors immediately drew students' attention to them if students did not notice their errors first. Later studies of tutoring, however, reported that tutorial feedback was not only infrequent but also unimportant to student learning (Graesser et al., 1995; Chi et al., 2001). Because the majority of the studies emphasizing the role of tutorial feedback came from studies of tutoring procedural skills (e.g., programming language, algebra, and geometry), it is likely that the value of immediate feedback on errors might be most useful in the procedural domain where following the right problem solving steps is important. However, there is considerable variability in how tutors handle errors even in the procedural domain. Some tutors provide explicit feedback, sometimes even telling students how to solve a problem (McArthur et al., 1990), whereas other tutors give very subtle and indirect responses to student errors (Fox, 1990; Lepper, Woolverton, Mumme, & Gurtner, 1993).

Another frequent tutor move during tutoring is giving explanations. Graesser et al. (1995) examined the tutoring of algebra and research methods and reported that one of the noticeable tutor behaviors was providing explanations along with specific examples that connected student understanding to concrete real-world examples. Chi and colleagues (2001) analyzed various tutor statements made by novice biology tutors in a naturalistic tutoring session, such as: (a) giving explanations, (b) giving feedback followed by short corrective explanations when the feedback was negative, (c) reading text sentences aloud, (d) making self-monitoring comments (e.g., "I don't know whether this will help you"), (e) answering questions that students asked, (f) asking content questions, (g) scaffolding with generic and content prompts, and (h) asking comprehension gauging questions (e.g., "is this starting to stick?"). Of the eight types of tutor statements they coded, the most prevalent tutor statement was explanations. Giving explanations is also frequent in the procedural domain (Anderson et al., 1989; McKendree, 1990), but the prevalence of explanation might vary depending on the nature of the content domain. Conceptual domains such as biology are more conducive to tutor explanations than procedural domains such as algebra. In addition, the role of tutorial explanations seems to be limited as they only correlated with shallow measures of students' learning (Chi et al., 2001) or not at all (VanLehn, Siler, Murray, Yamauchi, & Baggett, 2003).

Socratic Technique and Error Diagnosis Rare. Although tutors dominate the tutoring dialogue, this does not necessarily mean that they employ sophisticated tutoring techniques. One such technique that is absent in typical tutoring is Socratic technique. Socratic technique refers to a tutoring method in which the tutors lead students to discover their own misconceptions and construct understanding through a line of questioning instead of giving out information to students directly (Collins & Stevens, 1982). Socratic tutoring appears to produce superior learning outcomes compared with didactic tutoring (Rosé, Moore, VanLehn, & Allbritton, 2001), but it is rare not only in typical tutoring session involving novice tutors (Graesser et al., 1995) but also when tutors have years of experience (VanLehn et al., 2003).

Another tutoring technique that has often been attributed to tutors is the ability to perform a detailed and accurate diagnosis of student understanding especially with respect to errors and misconceptions. An accurate diagnosis and monitoring of students' misunderstanding is essential for tutors to be able to decide how and when to deliver the feedback and explanations and also to tailor their moves to the needs of individual students. Chi, Siler, and Jeong (2004) analyzed how accurately novice biology tutors diagnose and monitor the status of students' misunderstandings. The results indicated that tutors could assess only what students did not know against the normative understanding that the tutors were teaching and were dismal at diagnosing the students' alternative understanding or misconception. Additional evidence indicated that even experienced tutors did not engage in detailed error diagnosis and monitoring (McArthur et al., 1990; Putnam, 1987). It seems that tutors have some sense of what students understand and are aware of the general level of their competence, but are insensitive to the specific errors or misconceptions students have.

REASONS FOR TUTORING EFFECTIVENESS

In spite of the initial belief that tutors would play a critical role in tutoring, a closer examination of tutor behaviors revealed that their contribution is rather limited. This led to a realization that tutoring effectiveness needs to be examined from a broader perspective that considers not only what tutors do but also what students do in the context of interactive tutorial dialogue.

Tutorial Dialogue. To examine the potential mechanisms responsible for the tutoring effect, Graesser et al. (1995) studied the tutoring dialogues of unskilled tutors as they tutored algebra and research methods in psychology and examined the extent to which tutoring dialogues manifest

components that have been emphasized in contemporary pedagogical theories and intelligent tutoring systems. These components were: (a) active student learning, (b) sophisticated pedagogical strategies, (c) anchored learning in specific examples and cases, (d) collaborative problem solving and question answering, (e) deep explanatory reasoning, (f) convergence toward shared meanings, (g) feedback, error diagnosis and remediation, and (h) affect and motivation. Of these, only three components were prominent in a typical tutoring session: collaborative problem solving and question answering, explanatory reasoning, and anchoring in the context of specific examples.

Because most of the sophisticated techniques were underdeveloped or virtually non-existent in typical tutoring, Graesser and colleagues (1995) postulated that the tutoring effect would come from the use of localized strategies embedded within tutorial dialogues. They identified frequent dialogue patterns between tutors and tutees in the following five broad steps (p. 504):

1. Tutor asks a question.
2. Student answers question.
3. Tutor gives short feedback on the quality of the answer.
4. Tutor and student collaboratively improve the quality of the answer.
5. Tutor assesses student's understanding of the answer.

The first three steps of tutoring dialogue roughly correspond to the initiate, response, and evaluation cycle of the classroom dialogue in which the teacher initiates the dialogue typically by asking questions, the students respond, and then the teacher evaluates the responses. There are two extra steps in tutoring dialogue, however. Graesser and colleagues (1995) postulated that these extra steps of tutoring dialogue provided the advantage of tutoring over classroom instruction as tutors and tutees collaboratively construct knowledge during these steps.

Tutor-centered, Student-centered, and Interactive Hypothesis. Chi and colleagues (2001) conceptualized that tutoring effectiveness can be attributed to either what tutors do, what students do, or what tutors and tutees do together, and formulated three corresponding hypotheses: a tutor-centered, student-centered, and interactive hypothesis. The tutor-centered hypothesis states that tutors' pedagogical tactics are responsible for the effectiveness of tutoring and predicts that tutors not only employ sophisticated pedagogical moves during tutoring but also that their moves would make a significant contribution to students' learning. The student-centered hypothesis, derived from the findings that students' generative and constructive activities such as self-explanations aid learning (e.g., Chi, de Leeuw, Chiu, & Lavancher,

1994), states that tutoring is effective because it provides more opportunities for students to be generative and constructive. It predicts that students would be active during tutoring and that their active construction (e.g., question asking, self-explanations) would correlate with their learning outcomes. Lastly, the interactive hypothesis states that the key to tutoring effectiveness is not what the tutors or the students do alone, but the interaction between them. Tutorial interaction is critical because it elicits constructive responses from students. The hypothesis predicts that tutor and student would be interactive and that students' constructive and interactive responses (e.g., responding to tutor questions and scaffolding prompts) would foster learning more so than constructive but non-interactive responses (e.g., self-explanations) or interactive but non-constructive responses (e.g., acknowledgements).

In their analysis of naturalistic tutoring by novice biology tutors, Chi and colleagues (2001) found evidence for all three hypotheses. As for the tutor-centered hypothesis, tutors provided extensive amount of explanations, which was significantly correlated with student learning outcome. However, explanation was the only tutor move significantly correlated with student learning and did so only with shallow measures of learning. As for the student-centered hypothesis, they found that although tutors dominated the tutoring session, students were still more active during tutoring than in the classroom. Students asked far more questions during the tutoring sessions (e.g., about eight questions per hour) than in the classrooms (e.g., less than one question per hour according to Graesser et al., 1995). They also found that some of the students' constructive moves were correlated with learning outcomes, but they were all interactive moves (i.e., responses to scaffolding prompts and comprehension gauging questions), lending support to the interactive hypothesis as well. As for the interactive hypothesis, although tutors were not very interactive (after all, they dominated the tutoring session), students were. They never ignored tutors and always responded to prompts and questions from tutors. Tutorial interaction was also essential to student learning in that interactive construction was correlated with learning outcomes, whereas non-interactive construction was not.

Tutoring is a complex process. On the surface, it appears that tutors play a critical role in making it so effective. However, tutors in general do not use sophisticated tutoring strategies such as the Socratic technique or error diagnosis. In addition, even the tutorial moves frequently used by tutors such as explanations only made a limited contribution to students' learning. A deeper look at the tutoring session suggests that what students do in response to tutorial interaction also plays an important role. Being in a one-to-one situation with a tutor gives

students more chances to engage in active learning and to be constructive, but it is not merely students' construction that mattered. Student constructive responses elicited by tutor moves played a more important role in their learning than self-initiated constructive responses.

MAKING TUTORING MORE EFFECTIVE

Although tutoring is already a quite effective form of instruction, there is still room for further improvement. As Graesser and colleagues (1995) noted, many of the components that have been emphasized in contemporary pedagogical theories are either poorly executed or rare in typical tutoring situations. Thus, one obvious way to improve the effectiveness of tutoring is by training tutors in these missing pedagogical components. Although efforts to teach tutors to use specific strategies can be challenging, it seems that some of the strategies such as scaffolding seem to be relatively easy to implement (Chi et al., 2001).

Alternatively, tutoring can be made more effective by making tutors do less instead of trying to make them do more. Chi and colleagues (2001) also manipulated the kind of tutoring strategies tutors were permitted to use. In order to make tutoring less didactic and promote a more interactive style of dialogue, tutors were asked to refrain from giving explanations and feedback. They were encouraged to prompt the students instead. The results showed that students were just as effective at learning the materials even when tutors were suppressed from giving explanations and feedback. Even in the absence of tutor explanations and feedback, students were able to learn from a greater amount of scaffolding episodes as well as by taking greater control of their own learning by reading more.

COMPUTER BASED INTELLIGENT TUTORS

Computer-based intelligent tutors began to appear in the mid 1980s. These Intelligent Tutoring Systems (ITSs) heavily relied on the cognitive model of competence about how students learn and solve problems (e.g., Anderson et al., 1985; Anderson, Corbett, Koedinger, & Pelletier, 1995). A detailed cognitive model of students allowed computer tutors to trace students' problem-solving behaviors closely and provide directive step-by-step feedback to ensure that students stayed on the right paths. There are now well-tested tutors of algebra, geometry, computer languages, physics, and electronics (e.g., Koedinger, Anderson, Hadley, & Mark, 1997; Lesgold, Lajoie, Bunzo, & Eggan, 1988; VanLehn et al., 2005). According to one estimate, they produce learning gains of approximately 1.0 standard deviation units compared with students learning the same content in a classroom (Corbett, Anderson,

Graesser, Koedinger, & VanLehn, 1999) and are actively implemented and used in schools in the United States (Alevin & Koedinger, 2002; Koedinger et al., 1997).

In spite of their success, existing ITSs are often too rigid, allowing only one strategy for problem solving and providing perhaps too much scaffolding in the form of error correction. They are also limited in promoting deep learning, failing to help students to articulate reasons behind the problem-solving procedures and to apply what they learn to more qualitative problems (Alevin & Koedinger, 2002; Graesser, VanLehn, Rosé, Jordan, & Harter, 2001; Ohlsson, 1986; VanLehn et al., 2000). Several attempts have been made to remedy these shortcomings and make computer tutors as competent as expert human tutors. One approach, based on the research showing the importance of students' own construction activities, is to provide more opportunities for students to self-construct their understanding (Alevin & Koedinger, 2002). Another approach is to endow ITSs with natural language capability so that computers could engage in tutorial dialogue with students using natural language, thereby eliciting collaborative knowledge construction more actively (Graesser et al., 2001; Person, Graesser, Kreuz, & Pomeroy, 2001; VanLehn et al., 2000). The preliminary results from these attempts look promising. Students who explained their steps during problem-solving practice with a computer tutor learned with greater understanding compared to students who did not explain steps (Alevin & Koedinger, 2002). Students tutored by an ITS with natural language enhancement also outperformed students tutored with an earlier version of ITS without the enhancement (Graesser et al., 2001).

INSIGHTS INTO IMPROVING CLASSROOM INSTRUCTION

The tutoring effect demonstrates that most of the students have a potential to reach a high level of learning. In spite of its effectiveness, tutoring has not been used as actively and widely as it should be. The main reason has been the cost. There are ways, however, to circumvent this limitation and introduce the benefits of one-to-one tutoring into classroom instruction. One traditional solution is to use peer tutors. Because the majority of tutors are novices and yet produce significant effects, pairing students with other students of either same-age or cross-age across grades can be an effective alternative to using professional tutors. Peer tutoring can also help those students who serve as tutors since tutors themselves engage in active knowledge construction processes as they tutor (Roscoe & Chi, 2007). Peer-tutoring also brings other benefits such as community building and integra-

tion of students with diverse cultural and linguistic backgrounds (O'Donnell, 2006; Webb & Palincsar, 1996).

Benefits of tutoring can also be obtained by combining collaborative learning with tutoring. For example, Chi, Roy, and Hausmann (in press) examined the effectiveness of collaborative observation of tutoring against several other instructional conditions such as one-on-one tutoring and collaboration without observation. The results showed that students learned to solve physics problems just as effectively from observing tutoring collaboratively as the students who were being tutored individually. It seems that learning conditions such as collaborative observation of tutoring can serve as a promising alternative to one-to-one tutoring while providing all the same benefits.

Research on tutoring has demonstrated and reinforced the idea that students learn best if they construct knowledge for themselves rather than being told the knowledge. Tutoring seems to be a particularly effective form of instruction because it facilitates active knowledge construction within the interactive context of tutorial dialogues. Regardless of whether teachers implement tutoring into the classroom, classroom instruction can benefit greatly by finding ways to elicit more active construction from students in interactive contexts.

V

VALIDITY

Validity denotes the meaning of a test score or assessment result. Although historical notions of validity have suggested there are multiple forms of validity, contemporary views of validity consider it to be a unitary construct supported by distinct forms of evidence. Contrary to popular belief, validity is neither obvious nor intuitive. Therefore, the validity of any test or assessment, from teacher-made quizzes, tests, and assignments to published tests and procedures, should be established by collecting relevant forms of evidence so that educators can draw appropriate interpretations of assessment results.

HISTORICAL VERSUS CONTEMPORARY DEFINITIONS OF VALIDITY

Until the twentieth century, the validity of a test or assessment was determined primarily by the content of the assessment process. That is, a test was deemed to reflect mathematical skills if the questions on the test were primarily mathematical in nature; likewise, a test composed of questions about Elizabethan England was viewed as revealing a student's knowledge of history. However, advances in testing and assessment during the early twentieth century challenged these assumptions, in large part because the inferences about what tests were intended to measure changed from direct inferences (e.g., the student knows or does not know trigonometry) to less direct inferences (e.g., the student has strong or weak aptitude for quantitative reasoning). Therefore, the meaning of tests and assessments could not be directly inferred from test content. For example, the answer to the question "Who

wrote *Romeo and Juliet*?" could reflect a student's understanding of a unit on British literature, or it could be a reflection of a student's ability to acquire knowledge incidentally from the environment (especially if the student had not yet had a course in British literature). Content analysis alone is insufficient to determine whether the question was a measure of literary knowledge or student ability.

By the 1980s, assessment experts generally agreed that there were three types of validity: content, construct, and criterion (AERA, APA, NCME, 1985). The meaning of a test result was determined in part by the test's content, but also by evidence that the test result behaved in ways consistent with its theoretical construct (e.g., raw scores on a test of intelligence should increase with age up to the mid- to late teens), and should predict socially valued criteria (e.g., a mechanical aptitude test should predict grades in an industrial arts class). Test users could expect to have all three forms of evidence (content, construct, and criterion) available for published tests, while also recognizing some forms of evidence were more important for some test uses than others.

However, by the end of the twentieth century, professional standards redefined validity so that there was only one "type" of validity i.e., the meaning of a test score or assessment result (AERA, APA, NCME, 1999). However, standards outlined five forms of evidence needed to determine test score meaning: (1) content, (2) response processes, (3) internal structure, (4) relationships to other variables, and (5) test consequences. Test developers (and users) are expected to consider the forms of evidence most relevant to determining the meaning of a test result, and collect and provide relevant evidence to define the meaning of the test score or assessment result. Each of these forms of evidence is

Validity

described to help those who use assessment results (e.g., teachers, psychologists, administrators) to understand, demand, and collect such evidence.

Content. Primary evidence in this domain includes the specification of the intended content and expert judgment of test items regarding adherence to those specifications. For example, tests of state standards (required by the No Child Left Behind Act of 2002) are validated in part by specifying what students are supposed to know and do in a given domain, the degree to which these skills should be represented in a given test, and the cognitive complexity and type of item to be used to assess the skill. A reading test at third grade might therefore have more items devoted to phonological skills (e.g., grapheme/phoneme correspondence), word attack, and vocabulary than an eighth-grade test of reading, which might have fewer items for phonological and word attack skills, but more items reflecting inferential comprehension. For domains with less clearly specified content (e.g., intelligence), judgments regarding content are more dependent on theory than on exact specification of intended domains. In all cases, judges evaluate the test content against the intended interpretation of the test to evaluate the degree to which the test content represents the intended meaning of the test. Additionally, panels of judges with expertise in diversity (e.g., linguistic, ethnic, gender, religious) may also evaluate the content to identify any content that may be problematic for diverse groups.

Response Processes. The psychological processes test takers use when responding to an assessment are known as *response processes*. Evidence that a test elicits the processes it intends to measure, and only those processes, is useful for establishing the meaning of the test score. One cannot assume that a test item will elicit the intended process; for example, the item “Use a barometer to calculate the height of a tall apartment building” could elicit use of air pressure to estimate altitude, but it might elicit social knowledge (e.g., “Offer to give the barometer to the building superintendent in return for telling you the height of the building”). Test takers may get an item right (or wrong) without ever using the process intended to be elicited by the item. Forms of evidence supporting response processes are direct (e.g., ask test-takers how they solved items), and indirect (e.g., analysis of eye gaze, brain activity, or error patterns).

Internal Structure. Simply put, tests should behave the way the developers expect them to behave—meaning items purporting to measure the same thing should be more related to each other than items purporting to measure something different. For example, a mathematics test might intend to measure probability and geometry; if so, the items and subscales measuring probability ought to be more

related to each other than items and subscales measuring geometry. The primary forms of evidence, then, are internal consistency (items that measure the same thing should correlate with each other), and factor analysis (items should aggregate into common scales, and scales into expected patterns).

Relationships to other Variables. Assessment results ought to relate to measures outside of the assessment in ways that are consistent with the intended meaning. Evidence is often framed as *convergent* (i.e., the assessment should relate to things expected to be related), and *divergent* (i.e., the assessment should not relate to things that are expected to be unrelated). Forms of convergent evidence include grades given by teachers or scores on tests of similar constructs; forms of divergent evidence include a proposed independence between creativity and general intelligence (which rarely occurs, calling into question whether creativity is really different from general intelligence).

Test Consequences. Assessments are intended to benefit the test-giver and the test-taker. Therefore, test developers (and users) should collect and provide evidence that tests achieve their intended benefits, and avoid unintended consequences. For example, some argue testing mandates in No Child Left Behind benefit students by holding schools accountable for student achievement; critics argue that tests demoralize students and educators. The evidence needed to determine whether benefits are realized, or whether unintended consequences outweigh benefits, is often lacking from tests in educational settings. For example, in their 2005 study Braden and Niebling note that many popular cognitive ability tests claim to help educators match programs and instruction to student needs, but those promoting the tests do not actually provide supporting evidence.

A fundamental assumption is that no one form of evidence is sufficient to establish validity; rather, multiple forms of evidence must be presented and evaluated to support (or reject) an interpretation of a test score. Therefore, test users should obtain and weigh multiple forms of evidence to determine the validity of a test score or assessment result.

CRITICAL ISSUES IN ASSESSMENT VALIDITY

There are a number of issues that are particularly relevant to educators and educational settings. The following is a brief selection of critical issues.

Distinguishing Validity from Reliability. Validity refers to the meaning of a test score or assessment result, whereas

reliability is the consistency of a score or result. Consistency of assessment results is established over time (i.e., test-retest reliability or “stability”), agreement among test items (internal consistency), and agreement between raters (i.e., inter-rater reliability). A test that is not reliable cannot be valid; therefore, educators should evaluate reliability evidence before they even consider validity evidence. Reliability is most often expressed as a number, which is somewhat analogous to a percentage; reliability indexes of .80 (i.e., 80%) or higher are generally considered to be adequate for use in making educational decisions.

Causes of Test Score Invalidity. In addition to poor reliability, Messick’s 1995 study identified two causes of invalidity: *construct under-representation* and *construct-irrelevant variance*. Construct under-representation means the test inadequately taps what it intends to measure. For example, many multiple choice tests intend to measure skills ranging from lower order (e.g., recognition, recall) and higher order (e.g., analysis, synthesis, application, evaluation) skills. However, it takes time, energy, and expertise to create multiple choice items that tap higher order thinking skills, and so many multiple choice tests over-represent lower-order skills and under-represent higher-order skills. If the test purports to measure a broad range of cognitive skills, but has few items tapping evaluation and application, its scores will be invalid because they under-represent higher-order thinking in the domain.

Construct-irrelevant variance occurs when an assessment demands skills it does not intend to measure. For example, most reading comprehension tests intend to measure the test-taker’s ability to decode and comprehend written text. However, tests demand that the test taker has the visual acuity to discriminate the letters and words in the text. If the test-taker does not have that ability (e.g., the test-taker has an uncorrected visual impairment), then the test score will not reflect reading comprehension; instead, it will reflect the test taker’s skill in an unintended domain (i.e., visual acuity). In cases in which construct-irrelevant variance is high (e.g., limited visual acuity), the test-taker’s score will be invalid if the test taker lacks the construct-irrelevant skill.

Test Accommodations. The principles of construct under-representation and construct-irrelevant variance can help identify ways in which tests can (and cannot) be changed to accommodate test takers. Essentially, changes that reduce construct-irrelevant variance without creating construct under-representation are valid accommodations; those that either fail to reduce construct-irrelevant variance, or that reduce construct representation, are invalid accommodations. Returning to the example of a reading comprehension test, enlarging the text print, or allowing the use of eye-

glasses, reduces construct-irrelevant variance while maintaining construct representation, and is therefore a valid accommodation. However, reading the text to a person with a visual impairment is invalid, because it reduces construct representation (i.e., it under-represents decoding of text). It is important to note that test standards place the burden of proof for accommodation validity on the party recommending the change; the default assumption is that, in the absence of additional evidence, any changes to standardized assessment procedures and materials reduce the validity of the assessment result.

Assessment Bias. Assuming tests are equally reliable across groups (which is typically true), bias occurs when the meaning of the test score is different for one group relative to another (i.e., the validity is not consistent across groups). To determine if an assessment is biased, multiple forms of evidence must be presented showing different meanings for different groups. Simply looking at test content (e.g., claiming that a test is biased because it presumes cultural knowledge more prevalent in one group than in another) is insufficient to demonstrate bias. Most published assessments used in educational settings are not biased for groups whose native language is English; that is, the test scores represent the same thing for all groups of test-takers across ethnic, gender, and socioeconomic groups. Or to put it another way, tests generally reveal, rather than create, differences between groups. However, the validity evidence for test takers whose native language is not English is often limited, and less consistent, leaving open the possibility that assessment results have different meanings for native English versus non-English speakers. Simply noting that one group has lower scores than another is not in itself evidence of bias (i.e., groups can, and often do, differ).

Constructed versus Selected Response Assessments. Many educators and advocacy groups (e.g., Fairtest) are critical of selected-response or multiple choice tests. Critics contend that multiple choice tests emphasize low-level cognitive skills. Advocates of selected-response tests argue such claims are not supported by validity evidence, and they argue selected-response tests are reliable and cost effective. The bulk of evidence across the five validity domains suggests carefully developed assessments can overcome most limitations associated with item formats. For example, development of rubrics and rater training can produce adequate reliability in constructed-response assessments (e.g., performances, portfolios), and carefully constructed selected-response tests elicit higher-order cognitive processes. However, the greater costs in terms of time, scoring, and storing constructed-response assessments are not offset by better validity evidence, so most educational assessment programs primarily use selected-response assessments.

Validity

Teacher-developed Assessments. Most teachers have limited assessment training and even less time to develop and evaluate their own tests. Yet teachers routinely develop, administer, and score tests without considering validity issues. Some practical steps teachers can take to ensure student test scores reflect intended meanings include the following:

1. Develop student assessments before developing instructional units. By deciding in advance what students should know and do, teachers ensure content validity (e.g., breadth and depth of coverage), and can also align their instruction to ensure students learn the intended materials.
2. Specify assessment content and format with an item specification table. For example, a reading test might target 10% phonemic awareness, 20% alphabetic principle/phonics, 30% fluency, 15% vocabulary, and 25% comprehension distributed so that 50% of items are selected-response, 30% are fill-in-the-blank, and 20% are short answer. The resulting two-dimensional table helps teachers ensure content coverage is distributed as they intended, and also helps ensure that methods of assessment are distributed across content domains.
3. Provide multiple opportunities for students to demonstrate knowledge. Large-scale projects or final exams with a single score are less likely to be reliable, and therefore less likely to be valid, than a series of smaller, more frequent assessments.
4. Look for evidence that test scores might not convey intended meanings. Even tests developed by experts have unexpected problems; teacher-made tests are no exception. Teachers should look for evidence of unexpected outcomes (e.g., students who do well on quizzes do poorly on the unit test; items that nobody passes; evidence that groups differ in unusual ways on particular tests or items), and adjust tests if they conclude that the test did not accurately reflect its intended meaning.

Weighing the Evidence. Test makers and users want as much evidence as possible to understand what test scores mean. However, collecting and reporting evidence costs time and money, and so evidence is often incomplete. Test users must therefore weigh evidence to evaluate the degree to which it supports the validity, or intended meanings, of the test. Test users should invoke a four-step process to weigh evidence:

1. Identify the stated claims or purposes of the test.
2. Determine whether test scores have adequate reliability or consistency.

3. Decide which forms of evidence are most important.
4. Evaluate the degree to which the evidence supports intended meanings.

For example, suppose a test purports to measure mathematical knowledge and skills (step 1). Test users should decide what forms of consistency are most important (e.g., inter-rater agreement, stability), and then determine whether the test scores have reliability values greater than or equal to 0.80 (step 2). If the test has reasonable evidence of reliability, users should decide which forms of evidence are most salient. Achievement tests should have substantial evidence of test content (e.g., items should represent domains identified by the National Council of Teachers of Mathematics), internal structure (e.g., items purporting to measure common subdomains actually relate to each other), and relationships to other variables (e.g., the test correlates with other math tests). If the test also claims intended consequences (e.g., it will help plan educational interventions), then evidence showing how test scores enhance intervention selection, implementation, or outcomes should be provided. It should be noted that some domains (e.g., content) are more important than other domains (e.g., response processes). Finally, users should assess the evidence provided to judge the degree to which evidence supports the claims. Test reviews can be helpful, but test standards mandate that test users are personally responsible for ensuring that the tests they use have appropriate supporting evidence.

VISUAL IMPAIRMENTS

Vision is an integral part to standardized learning. Students who lack visual abilities often feel lost in a confusing educational maze. Although the U.S. Department of Education reported that less than 1% of U.S. students had visual impairments in 2004, the actual number of children with visual impairments is higher. The consequences of visual impairment can range from missed opportunities in learning to obstacles to gaining independence.

At one point the term *visual impairment* referred to an eye disorder at the tissue level, but subsequently, visual impairments took on a broader meaning to include the consequence of a functional loss of vision caused by a number of eye disorders.

VISUAL IMPAIRMENT DEFINITION

The definition of visual impairment includes a range of vision loss, including low vision. Specifically, it is defined as “an impairment in vision that, even with correction, adversely affects a child’s educational performance. The term includes both partial sight and blindness” (Pierangelo, 2007, p. 331). In the educational context, three terms describe levels of visual impairment.

The first level, partially sighted, refers to a visual problem that has resulted in the need for special education.

Low vision is used generally to refer to a severe visual impairment. The impairment is not necessarily limited to distance vision, but includes students with sight who are unable to read a newspaper at normal viewing distance, even with the aid of contacts, eyeglasses, or electronic devices. Students with low vision use a combination of vision and other senses to learn; they may require adaptations to lighting, print size, or provision of written materials in Braille.

Legal blindness is defined by vision of 20/200 or less in the better eye after correction, or limited field of vision (measuring 20 degrees at its widest point). Limited field of vision results in some confusion for students. Legal blindness also includes total blindness, or a person with “no vision or only light perception.” These are students who must receive instruction via aural methods, Braille, or other nonvisual media.

Visual impairments are caused by a number of eye disorders, including albinism, cataracts, retinal degeneration, diabetic retinopathy, glaucoma, corneal disorders, congenital disorders, and infection. Although the Department of Education listed fewer than 26,000 students age 6 to 21 as receiving special education services under the visual impairment category in 2004, the actual number is likely higher. Many students with visual impairments have other disabilities as well and are listed in those categories. Visual impairments actually occur at a rate of 12.2 per 1,000 people under age 18. Legal blindness occurs at a rate of .06 per 1,000 people under age 18.

ASSESSING VISUAL IMPAIRMENTS

Early assessment is key to helping a student benefit from appropriate intervention programs. Severe visual impairments are more easily identified in schools than milder vision losses. However, there are warning signs of visual impairment, such as lack of coordination in the eyes or excessive eye movement and blinking. Children who rub their eyes or who have frequent watering and signs of eye infections may need assessment for visual impairment. If children confuse colors, complain of headaches, or have poor posture when reading or writing, they may have vision impairment. More obvious signs include squinting, sitting very close to the chalkboard or screens, messy work, or complaining of difficulty seeing things clearly.

Among the goals set forth in the National Agenda for the Education of Children and Youths with Visual Impairments, Including Those with Multiple Disabilities, is Goal 6. It reads: “Assessment of students will be conducted, in collaboration with parents, by personnel having expertise in the education of students with visual impairments” (American Foundation for the Blind, 2005, p.1). Because the National Agenda emphasizes providing timely, quality educational services for children with visual impairments, initial and ongoing assessments are critical.

Students are assessed by a certified teacher of students with visual impairments (TVI). A functional visual assessment helps to determine how the children currently use any partial or low vision and what visual skills need further development or assistance. The TVI observes each child performing routine tasks and speaks with parents, teachers, and others involved in the child’s care about how the child uses vision. The child’s eye doctor also provides important clinical information on visual acuity, visual field, and diagnosis. A child with visual impairments may be examined by an ophthalmologist, who specializes in diagnosis and treatment of medical and surgical problems of the eye; an optometrist, who specializes in vision problems and treating vision conditions; and other providers such as an optician, who dispenses eyeglasses and other optical aids, or a low vision specialist.

Visual Impairments

The TVI will review the eye doctor's findings of visual acuity and summarize them on the report. The teacher also includes notes from observers and observes the child's visual skills from near and far distances. The teacher also observes how well the child sees objects that are to the sides, above or below the eye level to assess visual field, and notes other visual functions such as ability to localize, fixate, scan, track, and shift gaze. Eye preference and eye-hand coordination, as well as color vision, are additional concerns. The TVI observes the child in different settings and assesses visual abilities in relation to environmental considerations such as lighting, object size, and additional time to complete tasks. A team that consists of the TVI, parent or guardian, a general classroom teacher for the child, and other education professionals such as a school counselor or school psychologist, generally meet to make final recommendations and discuss the child's potential placement. The evaluation should include recommendations for services, adaptations, and instructional skills that will help the student learn.

Alternative media and tools such as books in Braille can aid the visually impaired student. WILL & DENI MCINTYRE/PHOTO RESEARCHERS, INC.

If a child has no vision, he or she still needs a functional visual assessment to confirm medical information and blindness, as well as noting recommendations for instruction modification.

CHARACTERISTICS OF CHILDREN WITH VISUAL IMPAIRMENTS

Many factors determine how visual impairments affect a child's learning experience. Age of onset and severity of vision loss, as well as presence of multiple disabilities, are some of the factors that make each child's situation unique. The U.S. Department of Education reported in 2004 that more boys than girls had visual impairment. As more and more infants are born prematurely, the incidence of visual impairments is expected to rise.

The cause of visual impairment and overall functioning level of a child also determine how the visual impairment affects a child's development. In general, visual impairments have cognitive, academic, social and emotional, and behavioral effects.

Restricted movement within the environment, particularly for children with congenital visual impairment, can affect a child's development. Children with visual impairments often have limited interactions with their environments, less reason to explore interesting objects, and as a result missed opportunities to learn. This lack of exploration may continue until some sort of intervention begins to motivate learning.

Academic performance may suffer for children with visual impairments, particularly in reading and writing. Alternative media and tools may help, such as Braille or an alternative form of print.

Children learn much about social behavior by observing others, so those with visual impairment may not understand nonverbal cues and other nuances of social behavior normally learned through imitation. The functional limitations caused by visual impairments may create obstacles to a child's independence as he or she ages. Studies have shown that some children with visual impairments can display social immaturity, more isolation, and less assertiveness than their peers.

Many myths surround children with low vision. In addition to later discovery of their visual impairment in some cases, those with low vision may not receive the adaptations and services they need as compared with their peers who are declared legally blind. Yet students who have low vision have unique social and emotional needs, such as identity issues, and they may need help with developing communication and self-advocacy skills.

Overall, children with visual impairments require assistance with technology, special print, auditory, or Braille materials. Other specialized needs depend on the

functional visual assessment and ongoing assessments concerning the child's development.

EXAMPLES OF EYE DISORDERS

More than 30 specific diseases and conditions are associated with visual impairments. An ophthalmologist can make the definitive diagnosis as to the cause of the visual impairment based on a physical examination and associated tests. According to a report from the U.S. Preventive Services Task Force, the most common causes of visual impairment in children under age 5 years are amblyopia and its risk factors and refractive error not associated with amblyopia. The common name for amblyopia is lazy eye. It develops in early childhood and involves one eye not working well with the brain, resulting in reduced vision in the affected eye. Amblyopia affects about two to three out of every 100 children.

Amblyopia may be due to effects of other conditions that interfere with normal binocular vision, such as strabismus (ocular misalignment), anisometropia (a large difference in refractive power between the eyes), cataract (lens opacity), and ptosis (eyelid drooping). In anisometropic amblyopia, the two eyes have different refractive powers; one can be nearsighted, while the other is farsighted. The misalignment of the eyes in strabismic amblyopia causes one eye to be used less than the other. The nonpreferred eye does not receive adequate stimulation, and the visual brain cells do not develop normally.

Refractive error not associated with amblyopia primarily includes myopia (nearsightedness) and hyperopia (farsightedness). These problems are correctable regardless of the child's age at detection.

Retinopathy of prematurity can blind a child. It generally develops in premature infants with low birth weights or less than 31 weeks of gestation. It is classified in five stages, from mild to severe. Diabetic retinopathy is a complication of diabetes, brought about by damage to tiny blood vessels in the retina. It is the leading cause of blindness in the United States. Retinoblastoma is a malignant tumor of the eye. Although it can occur at any age, it most often occurs in children younger than age five. The tumors may be present in one or both eyes.

Nystagmus is an involuntary movement of the eye that reduces vision. Typically, the movement is from side to side, but it can be up and down or circular. There are several forms of nystagmus. The condition may be hereditary and can result in severe reduction in vision. Students may need extra time for reading to scan text.

Strabismus is the misalignment of one eye and comes in several forms, such as esotropia, the inward turning of the eye, and exotropia, or outward deviation of the eye. Hypertropia refers to vertical deviation of the eye. Strabismus also can occur intermittently. The cause of strabismus

generally is unknown. Other disorders often are associated with strabismus, including retinopathy of prematurity, retinoblastoma, traumatic brain injury, hemangioma near the eye, Apert syndrome, Noonan syndrome, Prader-Willi syndrome, and others.

EDUCATIONAL PRACTICES

At one time, students with visual impairments were taught only in residential schools for blind children. Early in the 20th century, local school districts began educating students with visual impairments, but primarily in special classrooms. In the early 2000s, itinerant teachers, resource rooms, general education classes, and special schools all may be used in the education of students with visual impairments. By 2004 the U.S. Department of Education reported that about 90 percent of children with visual impairments spent at least some time in regular classrooms with peers.

The Individuals with Disabilities Education Improvement Act (IDEA) was introduced in 1975 and passed in 1990. It was reauthorized in 1997 and 2004 and includes provisions for children with visual impairments as defined above. Students with visual impairments also may be eligible for accommodations for general classroom inclusion under Section 504 of the Vocational Rehabilitation Act, passed in 1973.

The National Agenda for the Education of Children and Youths with Visual Impairments, Including Those with Multiple Disabilities is a grassroots effort that has helped improve education for children with low vision and blindness. In 2003 the National Agenda was updated to include 10 goals. The goals range from ensuring referral to an appropriate education program within 30 days of identification of suspected visual impairment to recommending ongoing professional development for those providing services to students with visual impairments. The National Agenda also encourages implementation of policies that involve parents as equal partners in the education process, that local education programs ensure access to a full array of services, and that access to educational and developmental services include assurance that materials are available to students in the appropriate media and at the same time as their sighted peers. Educational goals should be based on the assessed need of students with visual impairments and goals and strategies should be set throughout the student's life continuum.

The TVI works with local and national professionals as needed to provide access to educational materials for students with visual impairments. Students who are blind may use raised maps and charts and other materials to facilitate tactile learning. Many rely on auditory information from books on tape or CD-ROMs, spoken output from a computer, or tape computers, in addition to large

print or Braille materials. Each state has specific policies and practices for broad programming of curriculum. The National Agenda has an expanded core curriculum that describes the skill areas needed for students with visual impairments to prepare for a successful adult life. This curriculum goes beyond academic skills to include other considerations for the individualized education plan (IEP) team. Examples of expanded core curriculum areas are orientation and mobility, social interaction skills, career education, technology, independent living skills, and visual efficiency skills.

ASSESSMENT AND INSTRUCTIONAL ISSUES

Students with visual impairment should be included in general education when possible through careful assessment, strategies, and use of assistive equipment and materials. A TVI coordinates the instructional program. As children get older, it often is advisable to introduce them to adults with visual impairments so that they can experience normal work situations.

As stated previously, children with visual impairments may have difficulty with reading and writing and some low vision problems simply require more time for students. These issues can be particularly trying during standard testing at schools. The No Child Left Behind (NCLB) Act was signed into law in 2002 by President George W. Bush. The act revised the Elementary and Secondary Education Act, which is the primary federal law in precollegiate education. NCLB requires annual testing of all students in reading and math proficiency.

A student's functional visual assessment may need to include adaptation of achievement and other standardized tests such as those administered to satisfy school and state requirements under NCLB. The test may be conducted in Braille, on a computer, with magnification, or in a number of other ways, depending on the child's visual impairment. Responses may be given orally or through word processors or Braille writers. Scheduling accommodations such as extended time also may be made for students with visual impairments who need them.

There are challenges particular to educating students with visual impairments. Teachers who specialize in educating students with blindness and low vision often are isolated from their colleagues in the field because they may be the only TVI in the school district. They should remain connected with the larger community of professionals serving students with visual impairments. Some of the assistive devices for students can be difficult to find or expensive, so careful assessment, proof of need, and at times assistance from specialized resources may be required. Educators and parents of students with visual impairments should try to provide assistance to students

only when needed, within the guidelines of the assessment plan and IEP, and help students develop a sense of initiative and independence.

Teresa Odle

VOLITION

From the late 1980s to the late 2000s, psychologists analyzed personal qualities other than intelligence that predict accomplishments such as success in school. Qualities such as dependability and conscientiousness, which lead to high levels of competence, were recast in information processing terms. What underlies conscientiousness, for example, are wishes and desires that become goals and intentions, which must be implemented and protected from competing goals and other distractions (Kuhl, 1984). Duckworth and colleagues (2007) refer colloquially to a quality they call "grit," which they define as "perseverance and passion for long-

term goals.” Their “Grit Scale” reliably distinguishes students who attest to finishing tasks, persisting under difficulty, and overcoming obstacles from those students who say they tend to vacillate or are easily distracted on tasks. These authors find that “grit” plays a key role in leadership and other long-term achievements.

Cognitive-motivation researchers and positive psychologists alike recognized that there is something in the notion of purposive striving that cannot be captured within the concept of motivation, so they put a new interpretation on the old idea of willpower by returning to serious study of the psychological concept of volition. Volition is that quality of the will that takes a student from implementation to follow-through, reflecting an ability to persist in the face of difficulty. Whereas motivation denotes a process of goal setting leading to commitment, volition denotes a process of implementation leading to goal accomplishment. To the extent that volition helps a student to protect established goals and follow-through on tasks, it is highly important for success in academic settings such as classroom learning.

PROCESSES THAT CONTRIBUTE TO VOLITIONAL CONTROL

The key processes that define volition are the management, protection, and maintenance of attention, motivation, and emotion in tasks: Breaking a task into smaller pieces; beginning without procrastinating; resolving to avoid distraction and concentrate; thinking of the satisfaction completion will bring. Evidence of the ability for selective control of attention and emotion even in very young children has been shown to predict school performance later on (Shoda, Mischel, & Peake, 1990).

Psychologists offer a wide array of models that describe volitional processes. Some of the most cited are models of action control (Kuhl, 1984), effortful control, impulse control, emotion control, learned industriousness (Eisenberger, 1992), implementation intentions (Gollwitzer, 1999), and self-regulated learning or SRL (Corno, 2007). According to Boekaerts and Corno (2005), who reviewed research on self-regulation in education, there are several self-regulation processes that reflect volitional control; these include managing learning tasks, coping with distractions, focusing attention, and productively channeling emotions. In addition to these aspects of volition, SRL models highlight the role of motives and goals in strategy use and academic achievement (Zimmerman & Schunk, 2007).

Although volition theorists emphasize the conscious effort that a student makes to better manage learning, some go on to develop the idea that volitional processes can become automatized with repeated use and associated conditional feedback. Automization frees up mental resources for tasks over time, suggesting that volitional processes can

be transferred to new situations. Transfer across situations, as when there is evidence of automatically applied control on novel tasks, can lead students toward a volitional style of learning (a work style or work ethic) that again is suggestive of traits such as dependability.

STRATEGIES FOR MAINTAINING VOLITIONAL CONTROL

To better understand how volition develops, scholars identified the variety of explicit strategies used by students to manage, protect, and maintain their work efforts. For example, Corno and Kanfer (1993) adapted a list generated by Kuhl (1984) into two categories of covert and overt strategies used by students in educational settings. Both covert and overt (easily observable) strategies are aimed at protecting targeted goals from competing goals or other distractions, and managing negative affect.

The covert strategies studied by these authors included (a) metacognitive controls such as planning and self-monitoring; (b) motivation controls such as self-reinforcement, self-instructing, adapting tasks to make them more meaningful, and prioritizing target goals; and (c) emotion controls such as working out a timeline, controlled breathing in the face of difficulty, imagining rewards and satisfactions, and using available resources for conditional feedback. The overt strategies studied by these authors included controlling the task situation and others in the task setting. To control the task setting, students can create manageable sub-tasks, gather information and materials in advance, and avoid distractions. To control others in the task setting, students can take actions such as seeking assistance from teachers and supportive peers and asking bothersome peers to remove themselves. All of these strategies, whether overt or covert, are proactive, again aimed at managing, protecting, and maintaining focus on tasks.

To exemplify, imagine students who have decided to buckle down, pay attention, and do their schoolwork. Their challenge then is to avoid the idea of doing something else instead (e.g., to spend time with friends), however tempting and potentially more satisfying that alternative act might be. By prioritizing goals to get their work done over and above their competing social goals, and by regulating their emotional reactions to tasks (keeping negative affect at bay), students are using volitional control to manage an inner conflict. They are protecting their targeted goals and maintaining their efforts to achieve those goals. Imagine further that this scenario becomes automatic for more students in more academic task situations, so that the script for “concentrate got to” gets used adaptively by students whenever it is needed. That is the goal for educators who seek to help students move toward better volitional control.

**PERSON AND ENVIRONMENTAL
FACTORS THAT INFLUENCE
VOLITIONAL CONTROL**

Researchers have also studied the individual and contextual factors that support or impede students' abilities to exercise volitional control adaptively. They find that some students are predisposed, by orientation or developmental experience, to be more or less conscientious in their academic endeavors. For example, Snow and Lohman (1984) related volitional strategy use to cognitive ability; using a variety of indicators, they found that college students who score highly on standardized tests of cognitive ability consistently use effective organization and control strategies that maintain concentration while they complete the items. Kuhl (1984) found that a self-reported orientation to take action rather than procrastinate when confronted with decision-making tasks was also predictive of volitional strategy use and task completion in adults. In a different vein, research by Dweck (see Dweck & Master, 2007) linked children's early understandings of the relationship between ability and effort to expressed beliefs about their own capabilities (their "self-theories"); Dweck found that even intellectually able students may have underdeveloped volition if they doubt their own capabilities.

In regards to aspects of the learning context that support and promote self-regulation in students, researchers highlight the importance of teacher modeling (many different explained examples) of self-regulation processes and strategies, with reinforced use in appropriate class assignments. The earlier and more frequent such explanation, the better; like metacognition, volitional control develops experientially (Corno, 2000). This means that parents, too, can serve as role models, particularly in the early grades and when working with children on homework (Xu & Corno, 1994). In general, the evidence supports the idea that acquiring higher-order skills such as self-regulation demands a co-constructive or social learning process that includes evaluative feedback.

In the early 2000s teachers commonly use various forms of collaborative learning activities to create cohesion in the classroom community. Cooperative work and projects are situations in which students with good work habits can model and encourage their peers. These same settings can disadvantage students, however, if poor work habits are being modeled instead, or if there is no conditional feedback. When tasks are carefully structured to maximize opportunities for learning about, carrying out, and receiving reinforcement for self-regulation and co-regulation (as when pairs of students work together in cooperative tasks), there is a positive influence on volitional control. Classrooms in which students share in planning decisions about what material will be covered, when, and in what

venues will also support volitional control because this creates an "implementation intention" (Gollwitzer, 1999).

**EDUCATIONAL OUTCOMES
RELATED TO VOLITIONAL
CONTROL**

Volition influences continued motivation and affect as well as learning and long-term performance. There are potential downsides as well as upsides to volitional control. Gollwitzer's 1999 research on intention suggests, paradoxically, that people tend not to look back once they have firmly established goals that they value. Although this is good for keeping students on task, it also implies that letting go of goals that are impossible to accomplish will be difficult. The person so focused uses volition as a form of denial. Another potential downside of particularly strong volition is the development of an over-controlling or compulsive learning style that can induce a stress response to schoolwork. Stress of course can also trigger related negative affect. Finally, particularly strong volition can mask a sense of inadequacy, just as an easy sense of agency can fuel movement toward goals. There are advantages if students can learn to self-regulate in natural, almost playful, ways, using volitional control automatically under many tasks and circumstances.

The strong upside of adaptive use of volitional control is that it tends to result in the display of good academic work habits. These are the strategies and tactics for effective completion of academic tasks that are honed through experience (Corno, 2007). Work habits studied by psychologists include class participation, using feedback and other available resources, managing a workload, planning, and studying (i.e., habitual use of volitional control strategies). Students with good work habits tend to perform well in school, in part because they are putting in the dedicated learning time. But they also excel because they are recognized and given status as full participants in their academic communities; this recognition fosters a sense of efficacy for academic work that then has its own momentum (Zimmerman & Schunk, 2007). When students are viewed by teachers and parents as responsible and diligent workers, they are likely, ultimately, to benefit in other ways as well. Appreciation and rewards for hard work are given all along the age range (e.g., teacher recommendations, academic awards, nominations for leadership positions). Such acknowledgements are influential in decisions about college admissions and employment because they are predictive of success in these settings (see Willingham, 1985).

**DEVELOPING VOLITIONAL
CONTROL IN STUDENTS**

With respect to the combinations of instructional events that can promote development of volitional control in

students, techniques range from simple manipulations to school-wide programs. An example of the former is illustrated by Oettingen, Honig, and Gollwitzer (2000) who taught students an algorithm for making an action plan: determine when, where, and first steps for doing homework. Results showed significantly more of these students actually completed homework relative to comparable peers in a control group. As already stated, individual teachers can use a variety of techniques for teaching students about self-regulated learning. Perry (1998) provides examples of strategies for teaching young children; Randi and Corno (2000) offer a secondary-level curriculum based on a quest theme in which literary characters are shown to embody self-regulation. Counseling psychologists and special educators have refined cognitive-behavior modification procedures such as self-monitoring to make them useful with children who have impulsivity and behavioral control issues or learning disabilities (Butler & Cartier, 2004). Programs for time management have been adapted from the workplace (Corno & Kanfer, 1994). Even students who are temperamentally or stylistically less self-regulating can learn to use the management aspects and many other strategies of volitional control, particularly if they are motivated by feedback and incentives (Zimmerman & Schunk, 2007).

A more ambitious effort is evident in an after-school program designed to support the self-regulation and academic performance of middle school students (Oyserman, Terry, & Bybee, 2002). In this program, adults helped students plan for their futures and construct paths for achieving their goals; they thought about obstacles and how to work past them and had students learn from interviews with others who followed a similar path. The authors' evaluation of this program with inner city students found increased emotional engagement with school and better attendance and behavior as a result of the experience, particularly among troubled boys. Boekaerts and Minnaert (2003) report on a similarly comprehensive program aimed at vocational secondary schools in the Netherlands. In all of these education efforts, it remains important for teachers to encourage students and provide opportunities for them to practice volitional control in regular class work as well, that is, to afford and reward rather than constrain volitional control.

Educational researchers define volition as a quality of human functioning that takes a student from commitment to follow-through in academic tasks. Volition reflects an ability to avoid procrastination and to persist in the face of difficulty. To the extent that volition helps a student to accomplish school tasks, it is important for success in academic learning and performance.

The key processes that underlie volition are the management, protection, and maintenance of attention, moti-

vation, and emotion, aspects of self-regulation that tend to mark the efforts of exceptional students. Volitional control is evidenced in strategic task management, coping with obstacles and distractions, efforts to focus attention, and productive channeling of emotions. In addition to conscious regulation of thinking as they work, students often have implicit, habitual or automatized processes in place to maintain their effort. Volitional control has been measured reliably in children and adults by observation, interview, and self-report, and the research confirms that it can be manipulated experimentally.

When students use volitional control to manage conflicting goals, they work strategically to protect targeted goals and maintain efforts to achieve those goals. Adaptive use of volitional strategies as needed comes easier for some students than for others. Predisposing orientations that have been identified include high cognitive ability, an action orientation, "grit," and what Dweck (Dweck & Master, 2007) calls an "incremental theory of intelligence" (an understanding that personal efforts will aid improvement after failure). Students with these and similar characteristics or experiences are also likely to develop good academic work habits from the exercise of volition.

Volition affects continued motivation and affects as well as school learning. A moderate level of volitional control used flexibly appears to be the best target for educators, because then students are viewed by teachers and parents as responsible and diligent workers who can benefit emotionally as well. Other motivation processes, such as expectations of success, a goal to get the most from the material, even a hope to earn a better grade, can benefit from protecting goals and follow-through. These motivators, in turn, help to reinforce volition.

To promote the development of volition directly, teachers can encourage students and provide opportunities for them to practice volitional control in regular classroom tasks where they can receive pointed and constructive feedback. Practitioners can enlist competent peers to model self-regulated learning and use collaborative activities that allow students to feel they are active participants in the learning process. Just as in many other endeavors, to reach high levels of competence learners need an understanding of the concept and guided practice using volitional strategies over extended periods of time.

VYGOTSKY, LEV SEMENOVICH

1896–1934

Lev Semenovich Vygotsky (1896–1934) is best known for his theories of cognitive development in which he explored the importance of culture, language development, and the use of cognitive apprenticeships in the classroom. Although he was a prominent researcher in the Soviet Union during the cultural revolution, his writings were officially banned when Joseph Stalin (1879–1953) came to power and were overtaken in prominence by the growing influence of Jean Piaget (1896–1980). It was not until his works were translated from the original Russian several decades after his death that many European and American psychologists took note of Vygotsky’s writings and began to incorporate his theories into their research and teaching practices.

Vygotsky graduated from Moscow University in 1917 with a degree in law and a specialization in literature. While attending Moscow University, Vygotsky concurrently attended an unofficial, anti-tsarist institution known as Shinyavskii University where he studied a number of disciplines including history, philosophy, and psychology. These experiences led him to return to his hometown of Gomel, Byelorussia, to teach at a local teachers’ training college, where he also established his first psychology laboratory to study handicapped and mentally retarded children. In 1924 Vygotsky accepted

Lev Semenovich Vygotsky ARCHIVES OF THE HISTORY OF AMERICAN PSYCHOLOGY. THE UNIVERSITY OF AKRON.

an invitation to join the Institute of Psychology at Moscow State University (formerly Moscow University) where he completed his dissertation in 1925. He then founded the Experimental-Defectological Institute at Moscow State University II, where he advanced the field of special education by incorporating Marxist and other psychological influences into his research. At the end of Vygotsky’s career, political and cultural changes in the Soviet Union caused him to lose the directorship of the Institute, though he continued to remain on its faculty until his premature death in 1934 at the age of 37. Vygotsky was associated with a number of prominent Russian and Soviet researchers and theorists during his career, including his friend and colleague Alexander Romanovich Luria, and A. N. Leontiev. He was a contemporary of many notable psychologists, including Jean Piaget.

Though Vygotsky was not well known in Western Europe or North America until the late 1950s, his work in special education and cognitive development has led to important developments in classroom learning. For example, Vygotsky was a firm advocate for integrated classrooms in which disabled students are educated alongside their peers, and he is known as one of the founders of special

education. In addition, his theories on thought and language development are among the most well known of his contributions.

Vygotsky believed that “the most significant moment in the course of intellectual development, which gives birth to the purely human forms of practical and abstract intelligence, occurs when speech and practical activity, two previously completely independent lines of development, converge” (Vygotsky, L. S., 1978, p. 24). That is, when thought and language become one, the individual is able to analyze the world in more complex ways, to parse words and use them to form new meanings, and to organize thoughts. Vygotsky stressed that it is through the tools provided by language that meaning is assigned to what the child perceives, an act that is infused with cultural relevance. The words people use and the ways in which they use them convey certain elements of culture that are passed from one person to the next.

Through his theories of cognitive development, Vygotsky (1978) proposed that children develop most effectively and efficiently when they are engaged in tasks that are within their *zone of proximal development* which he defined as “the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers” (p. 86). In other words, children often learn best when they are given tasks that are slightly beyond their ability to perform alone, but can perform when aided by someone who is more cognitively advanced.

A discussion of Vygotsky’s work is not complete without reference to his proposition that development is situated within a culturally specific social-historical context. Vygotsky believed that development stems from relationships and social activities, whereby culture is imparted to the learner through both organized and unorganized activity. As Vygotsky sought to research various aspects of development, one of his primary concerns was to use appropriate methodologies. He believed that laboratory experiments, for example, were not appli-

cable to the real-world experiences of the participants. Instead, Vygotsky believed that it was important to study development within natural contexts. He also believed that the researcher should determine the most appropriate unit of analysis. In Vygotsky’s research, for example, he often broadened his unit of analysis beyond the individual to include ecological factors.

As a result of Vygotsky’s work, there have been a number of theoretical, methodological, and practical advances in psychology, education, and a wide variety of other disciplines. Barbara Rogoff’s influential concept of guided participation is a contemporary idea inspired by Vygotsky’s work. Also, many researchers have developed ecologically valid research methods. Developmental theorists have expanded Vygotsky’s work to discuss the ways in which culture, history, and context play important roles in human development. Lastly, many pedagogical techniques used worldwide stem from Vygotsky’s advocacy for the education of disabled students along with his theories of thought and language development and the zone of proximal development.

W

WEINER, BERNARD

1935–

Bernard Weiner was born in 1935 in Chicago, Illinois, the youngest of three sons of Russian immigrants. A product of Chicago's public schools, he received his undergraduate degree in Liberal Arts from the University of Chicago in 1955 and an MBA, majoring in Industrial Relations, from the same university in 1957. Following two years of service in the U.S. Army, Weiner enrolled in a PhD program in personality at the University of Michigan, where he was mentored by John Atkinson, one of the leading personality and motivational psychologists of that era. Weiner completed his PhD from Michigan in 1963, spent two years as an assistant professor at the University of Minnesota before joining the psychology faculty at the University of California at Los Angeles (UCLA) in 1965, where he remained active into the early 2000s.

Drawing on his intellectual roots in the field of motivation, Weiner was a leader in the study of attribution theory, one of the major theories of motivation in contemporary psychology. Attribution theory is concerned with the perceived causes of success and failure—for example, did a student fail an important test because of low aptitude or lack of effort—and the motivational consequences of particular attributions. Fundamental to attribution theory are the properties of causes (including their locus in the person or the world, perceived stability, and controllability), causal linkages to emotions and expectancy of success, and achievement performance.

For example, lack of aptitude is perceived to be an internal, stable, and uncontrollable cause of failure. Being

internal to the person, this attribution for failure reduces self-esteem; since it is stable, expectancy of future success is low; and because it is uncontrollable, feelings of shame are evoked. Low esteem, low expectancy, and shame give rise to poor performance. The factor of aptitude contrasts with lack of effort as the perceived cause of failure, which is unstable (thereby leading to high expectancy) and controllable (evoking guilt, a motivator of achievement rather than shame, an inhibitor). Attributional analyses help explain how individuals interpret their own achievement outcomes, but also the reactions of others. For example, teachers are likely to evaluate the failing student differently if his or her failure is perceived to be caused by low ability versus lack of effort. Thus attribution theory is both an intrapersonal theory of motivation (how one thinks about oneself) and an interpersonal theory of motivation (how others think about one).

Attribution theory provided educational psychology with the theoretical foundation for attribution retraining programs. Such programs are designed to improve motivation and achievement by changing maladaptive attributions for failure. For example, many attribution retraining studies with participants from elementary school through college have documented that students who are taught to attribute their failure to low effort rather than low aptitude are more likely to be optimistic about the future and to persist longer when they encounter academic challenges.

Weiner enjoyed an illustrious career as an attribution theorist. While he is best known to educational psychologists for his attribution research in the achievement domain, he also incorporated other social phenomena such as reactions to the stigmatized, help giving, aggression, excuse giving, punishment, and moral emotions. These phenomena are as

Bernard Weiner PHOTO COURTESY OF BERNARD WEINER.

relevant to educational psychology and classroom learning as the earlier attribution research on achievement strivings. Few other theories of motivation are amenable to such breadth of application.

As of 2008, Weiner had authored 13 books and published more than 200 articles in peer-reviewed journals. He was the recipient of numerous awards, including the Donald Campbell Research Award in Social Psychology from the American Psychological Association and the Palmer O. Johnson Publication Award from the American Educational Research Association. He holds honorary degrees from the Bielefeld University in Germany and Turku University in Finland.

Weiner is a recipient of a Distinguished Teaching Award from UCLA, a testament to his extraordinary ability to mentor students. Among his best known students who have had a significant impact in the field of education psychology are Jacqueline Eccles and Diane Ruble. His most frequent collaborator is a former student, Sandra Graham, also a colleague at UCLA.

WECHSLER INTELLIGENCE TEST

The Wechsler Intelligence Tests include three individually administered intelligence tests, appropriate for preschoolers through adulthood. The Wechsler Preschool and Primary Scale of Intelligence (3rd ed.) (WPPSI-III) is appropriate for children ages 2 years 6 months to 7 years, 3 months (Wechsler, 2002); the Wechsler Intelligence Scale for Children (4th ed.) (WISC-IV) is used for children and adolescents ages 6 through 16 (Wechsler, 2003); and the Wechsler Adult Intelligence Scale (3rd ed.) is used for assessment of those ages 16 and older (Wechsler, 1997). All scales are derived, directly or indirectly, from the Wechsler-Bellevue Intelligence Scale (Wechsler, 1939), and adult intelligence test developed by David Wechsler at Bellevue Hospital. The original WISC was a downward extension of the adult scale, and the WPPSI was a downward extension of the WISC. The three tests thus share a common heritage, structure, and interpretation. Although David Wechsler died in 1982, he continued into the early 2000s to be listed as the author of the Wechsler tests. This entry concentrates primarily on the WISC-IV, the measure most commonly used with school-age children, but many of the comments apply to the other Wechsler scales, as well.

In school settings, the WISC-IV is administered by school psychologists to children referred for a variety of academic and behavioral concerns. The test, administered as part of a battery of intellectual, academic, behavioral, and social-emotional measures, can be useful in differential diagnosis (e.g., mild mental retardation versus low average functioning) and in understanding a child's academic weaknesses (e.g., a problem in reading comprehension may be, in part, the result of low verbal reasoning skills).

Wechsler tests have traditionally included multiple subtests with both verbal and nonverbal content. Brief descriptions of the 15 WISC-IV subtests are shown in Table 1. Ten of the subtests are standard, or core subtests, and are given to all children. Five of the tests are supplemental, meaning that they are not generally used in the calculation of composite scores or IQs; they may

Scales and subtests of the Wechsler Intelligence Scale for Children—Fourth Edition		
Scale	Subtest	Description
Verbal	Similarities	Explain what two words or concepts have in common
	Vocabulary	Defining words
	Comprehension	Answering practical problem-related questions (e.g., why do we put stamps on letters?)
Perceptual reasoning	(Information)	Answering general information questions
	(Word reasoning)	Identifying the common concepts from verbal clues
	Block design	Arranging red and white two-colored blocks to match a pattern
	Picture concepts	Picking pictures that share a common characteristic
Working memory	Matrix reasoning	Completing an unfinished matrix of symbols
	(Picture completion)	Identifying missing parts in drawn pictures
	Digit span	Repeating digits in forward and reversed order
Processing speed	Letter-number sequencing	Series of letters & numbers are presented orally. Examinee recalls numbers in order first, then letters
	(Arithmetic)	Answering oral arithmetic word problems
	Coding	Quickly writing symbols associated with numbers or shapes (younger children)
	Symbol search	Marking the re-occurrence of abstract symbols
	(Cancellation)	Speeded selection of a category (e.g., animals) of pictures

Note: Supplemental subtests are enclosed in parentheses.

Table 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

be substituted for standard tests, however, if subtests are spoiled or are not given.

For previous versions of the WISC and the other Wechsler Scales, the subtests have traditionally been summed to create verbal and nonverbal (performance) IQs, as well as a full scale IQ designed to estimate general, overall, intelligence. Despite this traditional scoring, factor analyses have long suggested that the various Wechsler Scales were measuring more than just verbal, nonverbal, and general intelligence. The WISC-IV represents a major departure from this tradition; as shown in the Table, the WISC-IV subtests are combined to create verbal, perceptual reasoning, memory, and processing speed indexes (a full scale IQ, representing a composite of all 10 standard subtests, is still calculated). The structure for the WISC-IV was changed in order to make the instrument more consistent with research and with contemporary theory concerning the structure and nature of intelligence (Zhu & Weiss, 2005); presumably the subsequent revisions of the WAIS and WPPSI will also show considerable change.

Research (Keith, Fine, Reynolds, Taub, & Kranzler, 2006) suggests that the verbal scale of the WISC-IV indeed measures verbal reasoning skills, or crystallized intelligence from a three-stratum (Carroll, 1993) or Cattell-Horn-Carroll (CHC) (McGrew, 2005) theoretical orientation. Likewise, it appears that the processing speed index of the WISC-IV provides a measure of processing speed, and the full scale IQ is a valid measure of general

intelligence, or g. The perceptual reasoning tests of the WISC-IV, in contrast, appear to measure a mixture of visual spatial abilities and fluid intelligence (also known as novel reasoning). The working memory index of the WISC-IV, excluding the arithmetic subtest, appears to assess working and short-term memory skills. Arithmetic, however, may measure a mixture of intellectual abilities, chief among them quantitative knowledge or quantitative reasoning, a narrow ability subsumed under the broad ability of fluid intelligence. Interestingly, the arithmetic subtest is among the best single measures of general intelligence on the WISC-IV (Keith, Fine, Reynolds, Taub, & Kranzler, 2006).

The full scale IQ and the four index scores have a national mean of 100 and a standard deviation of 15 for each age level. Thus, because the scores conform to a normal curve, approximately 68% of children and adolescents will have scores between 85 and 115. The subtests use a different standard score metric: they have a mean of 10 and a SD of 3. A report of assessment results using the WISC-IV will generally include a listing of the full scale and index scores, including percentile ranks for those scores and confidence intervals around the scores. Such scores will often be interpreted with statements such as “Johnny’s IQ score was higher than 34% of children his age, and there is a 90% chance that his true FSIQ is within the range of 90–98.”

One perceived historic advantage of the Wechsler scales over the Stanford Binet, the most common individual

intelligence test prior to the advent of the Wechsler scales, was that the multiple IQ (now index) scores and subtest scores allowed the analysis of a profile of scores for an individual. There is often considerable variability in children's performance on the various tasks, and many psychologists believe that a child's pattern of strengths and weaknesses is useful in understanding that child's cognitive functioning and in remediating academic weaknesses.

There is considerable debate about the efficacy of profile analysis, however, with critics contending that profiles rarely produce reliable information and that the most general score (the full scale IQ) is generally the only one that should be interpreted (Watkins, Glutting, & Youngstrom, 2005). It is certainly the case that profile analysis can be overdone, but its cautious use often is helpful in understanding the strengths and weaknesses of children referred for academic and behavioral concerns. Such an approach generally focuses on a top-down approach in which the most general score is interpreted and more specific scores are only interpreted when there is unusual variation in scores. This *intelligent testing* also proceeds in steps from interpretation of the IQ, to the indexes, to combinations of subtests that theory and research suggest measure common psychological constructs. Examiners look to other test results and background and interview information to support or reject hypotheses generated. Such an approach to interpretation of the WISC-IV is explained in Flanagan and Kaufman (2004). To use this approach validly, one obviously needs a strong understanding of the constructs measured by the test being interpreted.

The WISC-IV is well standardized and has a long clinical and research history. The test likely provides reliable and valid estimates of general intelligence and several important broad cognitive abilities. There are also inconsistencies in the scoring structure of the WISC-IV and what the test likely measures, which make interpretation of some of the scores produced difficult. Although more consistent with intelligence theory and research than previous versions of the WISC, the test still has room for improvement.

At one time the Wechsler Scales were among the few choices available for individual intellectual assessment. As of 2008 there are numerous other possibilities. Other possible measures include the Differential Abilities Scales, Second Edition (ages 2 years 6 months through 17) (Elliott, 2007), the Kaufman Assessment Battery for Children, Second Edition (age 3 to 18) (Kaufman & Kaufman, 2004), the Stanford Binet Intelligence Scales, Fifth Edition (ages 2 and older) (Roid, 2003), and the Woodcock Johnson III Tests of Cognitive Ability (ages 2 and older) (Woodcock, McGrew, & Mather, 2001, 2007).

Unique in its focus on the dynamic between student and teacher, *Psychology of Classroom Learning: An Encyclopedia* provides a psychological examination of the factors in the classroom that help determine the success of today's student. The nearly 300 signed, alphabetically arranged topical essays provide a contemporary view of how instruction and learning are affected by elements such as classroom management, multiculturalism, motivation, home schooling, peer relationships, school culture, discipline, self-esteem, socioeconomic status, and more. Many of the topical entries are enhanced by statistical charts and other illuminating sidebars, and the set features extensive cross-references, a thematic outline, and a subject index. *Psychology of Classroom Learning: An Encyclopedia* also includes biographical entries on leaders in educational psychology.

Psychology of Classroom Learning: An Encyclopedia broadens Gale's collection of encyclopedias in the Macmillan Social Science Library, making it a companion to *Encyclopedia of Sex and Gender*, *Encyclopedia of Race and Racism*, and *International Encyclopedia of the Social Sciences*.
