Besides the two broad subcategories of externalizing and internalizing problems, EBD includes many other types of disorders. Kauffman and Landrum (2009) describe several subcategories of difficulty: attention and activity disorders, conduct disorders (which may be overt aggression or covert antisocial behavior), special problems of adolescence (which include delinquency, substance abuse, and early sexual activity), anxiety, depression, and schizophrenia. Many types of disorders can occur together. A case in which a particular individual exhibits simultaneous occurrence of disorders is described as comorbid. In fact, multiple or comorbid disorders are more common than are single difficulties.

Most students with EBD are not what most people would consider psychotic—unable to tell the difference between reality and unreality. However, a few students with EBD have schizophrenia, a major thought disorder that often includes hallucinations and delusions. For these students, antipsychotic medication, as well as appropriate education, is extremely important.

INTERVENTIONS AND INSTRUCTION

Intervention based on behavior principles is the most effective way of responding to EBD, as explained by Hallahan and Kauffman (2009), Kauffman and Landrum (2006, 2009), Stichter and colleagues (2008), and Hill Walker, Elizabeth Ramsey, and Frank Gresham (2004). Other interventions may appeal to one's intuition or tradition, but they tend to be less reliable and may make problems worse. Behavior principles emphasize instruction in how to behave, support for desirable behavior, and other primarily positive interventions, although effective, nonviolent, and appropriate punishment procedures may sometimes be necessary. Application of these behavior principles in teaching is also described by James Kauffman, Mark Mostert, Stanley Trent, and Patricia Pullen (2006), by Mary M. Kerr and C. Michael Nelson (2006), and by Landrum and Kauffman (2006). A

behavioral approach relies primarily on using consequences to change behavior, although instruction, talking to students, and correcting environmental factors that set the stage for misconduct are also important. Skillful application of these principles should address the problems of students with EBD, as Hill Walker, Steven Forness, and colleagues (1998) have suggested.

Appropriate academic instruction plays a primary role in programming for students with EBD and in classroom management. In fact, Kauffman, Mostert, Trent, and Pullen suggest that a teacher who is having difficulty with a student's behavior should first consider academic instruction. Joseph Witt, Amanda VanDerHeyden, and Donna Gilbertson, as well as Kathleen Lane, emphasize the importance of educators having instruction in academic skills in helping students with EBD.

Psychopharmacology plays an increasingly important role in managing EBD. The role of drugs can be overplayed or misunderstood, but medication is clearly important not only in managing such problems as attention deficit hyperactivity disorder (ADHD), depression, bi-polar disorder, and schizophrenia but also in making students with these disorders more accessible to instruction (see Steven Forness & Kelli Beard; Steven Forness, Stephanny Freeman, & Tanya Paparella; and Dean Konopasek & Steven Forness).

ISSUES IN ASSESSMENT AND EDUCATION

A major problem in assessment is fear of false identification. In fact, this fear is so common that students with EBD typically are known to have serious problems for years before they are identified, and the evidence for EBD must be so overwhelming that almost no one can argue that the identification is unjustified. Of course, such fear kills any hope of prevention, as Kauffman has pointed out.

No one suggests letting behavior problems fester until they become severe, protracted, and nearly insurmountable, yet that is what typically happens, as Kauffman, Walker and his colleagues (2004) and Phillip Wang and his associates (2005) have observed. In fact, Glen Dunlap and his colleagues present the consensus of researchers in the field that early identification of children with challenging behavior (EBD) is possible and more effective than later intervention. Moreover, Wang and his fellow researchers wrote that "long periods of untreated illness may also be harmful to those with less severe disorders" and that "most people with 1 disorder progress to develop comorbid disorders and such comorbidity is associated with an even more persistent and severe clinical course" (pp. 610-611). Thus, the case for early identification and prevention has been made

clearly, yet prevention is not typically put into practice (see Dunlap & colleagues; Kauffman). Early identification and prevention are not controversial ideas; however, when they are put into practice, controversy can arise. Complications regarding labeling, privacy, disproportionate identification of children by ethnic or color group, and doubt about misdiagnosis result in inaction.

Violence in schools is recognized as a serious problem; however, few schools use what is known about violence prevention. Get-tough policies and harsh punishment for aggression, the usual responses, are mostly counterproductive. The best approaches include school-wide behavior monitoring and behavior management procedures that emphasize careful monitoring, clear expectations, reward for desirable behavior, and nonviolent negative consequences for behavioral infractions, which have been described by Walker and his colleagues (2004) and by Kerr and Nelson (2006). However, although some EBD students commit violent acts, most do not.

The placement of students with EBD has been a matter of special concern and controversy in the context of movement toward full inclusion, the idea that all students should be placed in general education classes in their neighborhood school regardless of their disabilities (see Kauffman and Hallahan, 2005b). The placement in general education classrooms of many students with EBD is not feasible, as James Kauffman, John Lloyd, Teresa Riedel, and John Baker have suggested. The idea of basing all services for all students with EBD in the communities where they live is appealing, and community-based services are clearly feasible for some. However, closing all hospitals and residential placements for students with severe EBD and attempting to provide all services in the community has not proven feasible (Hallahan & Kauffman; Kauffman & Landrum, 2009). Effective programs for students with EBD are expensive, and inclusionary programs and community-based services promise savings for taxpayers. The anticipated cost saving makes inclusionary, community-based programs popular, although research does not show them to be particularly effective.

Adolescents and young adults with EBD are among the most frequently unemployed individuals with disabilities. Helping students with EBD make the transition from high school to work or to further education is among the most difficult tasks in special education, as Douglas Cheney and Michael Bullis have noted. Programs for the transition of students with EBD have been criticized as unsuccessful, but they are often criticized for other reasons as well. Critics may claim that they represent consignment of students to second-class citizenship or that they emphasize vocational skills when they should be focused on academic preparation for higher education.

In fact, any schooling different from that for students headed for college is vulnerable to charges that its expectations are too low.

Students who are members of ethnic minority groups in the United States, particularly African Americans, are disproportionately identified as having EBD. Although the reasons for disproportionality have not been identified unambiguously by research, multicultural special education is considered essential (Hallahan, Kauffman & Pullen, 2009). That is, special education teachers need to be sensitive to and respectful of cultural differences, but they may not understand how to do so and much of the education literature is unclear on the subject. James Kauffman, Maureen Conroy, Ralph Gardner, and Donald Oswald have suggested that effective, evidence-based education is culturally neutral and that culturally sensitive education demands attention to the individual student from a scientific perspective. Although science itself has been criticized as culturally biased, that criticism has been resoundingly rejected by many special educators, exemplified by *Challenging the Refusal of Reasoning in Special Education*, edited by Mark Mostert, Kenneth Kavale, and James Kauffman. About ethnicity, Kauffman, Conroy, Gardner, and Oswald concluded that “first and foremost we must recognize that the most culturally responsive practices are empirically validated instructional strategies. . . . At this point the data seem to suggest that this applies to all children, regardless of their ethnicity.”

James M. Kauffman

EMOTIONAL DEVELOPMENT

Along with physical and cognitive development, every child progresses through phases of emotional development. Arguably, all children differ in their individual development. Studies have shown that parents admit to having little information on emotional development, even though they also admit that their actions have great influence on their children's emotional development.

Emotions are not as easy to study or recognize as cognition, and for many decades the study of emotional development lagged behind study in other areas of child development. However, by the early twenty-first century researchers had developed several theories on emotional development.

EMOTIONAL DEVELOPMENT DEFINITION

Emotional development is the emergence of a child's experience, expression, understanding, and regulation of emotions from birth through late adolescence. It also comprises how growth and changes in these processes concerning emotions occur. Emotional development does not occur in isolation; neural, cognitive, and behav-

ioral development interact with emotional development and social and cultural influences, and context also play a role. Various emotional development theories are proposed, but there is general agreement on age-related milestones in emotional development.

Social and emotional development are strongly linked and sometimes studied or reported in tandem. Parents and other caregivers play an important role in emotional development, but as a child's world expands, other people in the social context also play a part in emotional development.

Debate continues as to exactly when emotions appear in infants. For example, smiles occur early, but the earliest ones are more likely reflexive than social. A smile may express emotion as early as 6 weeks of age but it is not until about age 6 months that a smile can be considered more emotional and social in nature. Crying is a powerful emotion for infants and may be used as a communication tool. Distress, pleasure, anger, fear, and interest are among the earliest emotions that infants express. Laughter begins at about 3 to 4 months of age. Eliciting laughter in babies at this age often involves an action that deviates from the norm, such as peek-a-boo games provoke. Development of negative emotions probably follows soon after, with anger still winning over sadness to express negative feelings. Fear begins to emerge, and infants often follow the emotions of their caregivers and form strong attachment to them.

By toddlerhood and early childhood, children begin to develop more of a sense of self. Emotions such as pride, shame, and self-recognition begin to emerge. These developments are facilitated partly by the rapid maturation of a toddler's frontal lobes and limbic circuit in the brain. These emotional developments lead to the strong sense of independence and defiance that often characterize the toddler years. Of course, toddlers also are becoming more independent physically, having developed skills such as walking. They may begin to play independently too. The self-recognition brings new levels of emotional development. For example, toddlers will begin to respond to negative signals from caregivers and others. It is at the toddler stage, or at least by age 2, that children also begin showing empathy, which is a complex emotional response to a situation. Feeling empathy requires that a child not only read emotional clues from others but understand the distinction between self and others. Actually putting one's self in the other's position also is required for empathy.

Emotional expression is still largely nonverbal, although some emotional language may develop by age 20 months. For the most part, facial expressions, crying or other vocal expressions, and gestures still express many of toddlers' emotions. In early childhood, verbal skills develop and with them, verbal reasoning. Children also

are able to talk about their feelings as they learn how to express themselves verbally. As young children enter preschool, they may be able to label their emotions and learn about them by understanding family discussions and actions concerning emotions. For example, a child may be able to say, "I am mad," or "I am sad," instead of simply expressing the emotion through actions such as crying, stomping, or yelling. This is not to say that tantrums do not occur; between toddlerhood and school age, children still express anger in the form of tantrums. Because emotions have become important to young children, they talk about them often in conversation.

Preschoolers begin to understand the rules of family, school, and society concerning how they express some of their emotions. They also can recognize nonverbal cues of emotion from one another. Preschoolers begin to distinguish between negative emotions such as sadness, anger, and fear. Although these young children have empathy, their knowledge of others' feelings generally is limited to people and situations with which they are familiar. Development of this emotional capacity also depends on positive, culturally acceptable emotional exchanges with peers. Negative emotional influences of family life that are common and harsh, particularly in the child's discipline model, can lead to problems with emotional development and even psychopathology.

ENTERING SCHOOL

As children enter school, they gain a greater sense of self and an understanding of how specific situations can lead them to experience emotions. Children may experience shame, even in reaction to emotions expressed. They also can begin to understand how an event can lead to mixed emotions. Research has shown that by about age 6, children may appreciate that people can experience one emotion, then a completely different emotion immediately after the first. The understanding of simultaneous and even conflicting emotions soon follows.

As children move into later childhood, they learn the "rules" of displaying emotion, which is a form of social and emotional development. For example, if children have been taught to do so, they may, out of politeness or respect, be able to avoid showing disappointment in a gift or the failure of an adult to fulfill a promise. As they understand the emotional states of those around them, children realize that these states are not as simple as they might have once imagined.

School-aged children begin developing emotional coping skills, even if those skills are at very basic levels. For example, children may rationalize situations and behaviors or reconstruct scenarios to make them seem less upsetting emotionally. The ability to suppress negative emotions is a factor of normal development, as well

as other influences, such as gender, the specific situation, cultural influences, and the person likely to receive the expressed emotion.

In adolescence emotions still are developing. In fact, the adolescent years often are considered an emotional period of development. Although adolescents begin to develop independence from their parents and begin to display social signs of independence by gaining employment, driving, and other activities, their emotional autonomy is represented by conflict and often negative emotions. One reason for the negative emotions may be cognitive development of abstract thinking abilities. Because adolescents can imagine all sorts of complex and theoretical scenarios for romance or in response to other relationships, they may suffer resulting emotional distress. In turn, social problems become more complex, and adolescents look to their peers to help provide a basis for how to manage the emotions they feel.

Family issues and struggles over becoming independent, with curfews, academic pressure, and romantic and other peer interactions, all place a great deal of pressure on adolescent emotions. Strong self-perceptions from earlier childhood may give way to self-doubt or feelings of worthlessness. As adolescents realize that their emotions are separate from their parents' emotions, a process called "emotional autonomy" begins. Adolescents may feel pulled between the close emotional ties they have with their parents and a need to develop independent emotional responses. If depression is going to occur, it generally begins during adolescence and is more common in girls than in boys.

EMOTIONAL REGULATION

A major part of emotional development in children and adolescents is how children recognize, label, and control the expression of their emotions in ways that generally are consistent with cultural expectations. This is called *emotional regulation*. In short, development of an emotion almost is dependent on regulation. The exact definition and models of emotional regulation have been debated. But what is apparent in the study of child and adolescent development and the development of positive instructional strategies is the complex interaction of emotional regulation and development of emotions.

Self-regulation of emotions includes recognition and delineation of emotions. Once a child can articulate an emotion, the articulation already has a somewhat regulatory effect. Children may be able to use various techniques to self-regulate as they develop and mature. Children begin learning at a young age to control certain negative emotions when in the presence of adults, but not to control them as much around peers. By about age 4, children begin to learn how to alter how they express

emotions to suit what they feel others expect them to express. The ability to do so is what psychologists call *emotional display rules*.

By about age 7 to 11 years, children are better able to regulate their emotions and to use a variety of self-regulation skills. They have likely developed expectations concerning the outcome that expressing a particular emotion to others might produce and have developed a menu of behavioral skills to control how they express their emotions. By adolescence, they adapt these skills to specific social relationships. For example, older children may express negative emotions more often to their mothers than to their fathers because they assume their fathers will react negatively to displays of emotion. Adolescents also have heightened sensitivity to how others evaluate them. Their self-consciousness and the culture-specific nature of guidelines concerning the appropriateness of emotional expression make this a particularly difficult time to learn when and how to express or regulate many emotions.

Several emotional development models and perspectives present views on emotional regulation. The functionalist perspective emphasizes that emotions serve a function of focusing action to achieve personal goals. Self-regulation is critical to emotional development because it marks a progressive ability to regulate emotions according to demands of the physical and social worlds. Actions match the demands of the situation and each family of emotions provides a range of behavior-regulatory, social-regulatory, and internal-regulatory functions for an individual.

The perspective of emotions as discrete states is based on understanding emotions as patterns of configurations in the brain, as demonstrated in cognitive neuroscientific studies. Neurochemical processes result in subjective feeling states, with accompanying automatic changes in bodily function and behavior. These give rise to basic emotions. Specific sections of the brain are associated with particular emotions. For example, the right prefrontal cortex is associated with negative affect and withdrawal. Theorists propose a maturational timetable for emergence of these basic emotions, beginning in infancy. Emotional development and regulation are dependent on cognition for the most part; cognitive development leads to new abilities to understand and self-regulate basic emotions.

Process viewpoints, also known as systems perspectives, do not disclaim the functional utility of emotions or their grounding in discrete feeling states. But the perspectives focus on how emotions emerge from one's tendency to self-organize various interacting components. These components include felt experiences, cognitive appraisals, motivations, functions, and control elements. This perspective leaves emotional regulation dynamic and open to transformation, as emotions are complex

and specific to situations. They also help form the basis of one's self and personality. Like functional and discrete state perspectives, systems theories maintain that emotions can serve adaptive functions for a child, especially in social situations.

EMOTIONS AT SCHOOL

The interplay of emotional development, social development, and academic performance is complex. C. Cybele Raver's 2002 research has established a strong link between social/emotional development and behavior and school success, particularly in the first few years of schooling. If a child's academic tasks are interrupted by problems with peers, following directions, or controlling negative emotions, the child will have trouble learning to read or staying on task in other educational activities. Research also has linked antisocial behavior with decreased academic performance.

Emotional understanding can positively relate to adaptive social behavior, yet it can negatively relate to internalizing behavior. This may lead to feelings of anxiety, depression, and loneliness. Knowledge of emotion can affect verbal ability, and in turn, academic competence. Verbal and prosocial skills are critical to academic achievement. For example, a child must be able to communicate with his or her teacher, which includes reading emotional cues. Children who do not learn to regulate emotions and who display disruptive behavior in school spend less time on tasks and receive less instruction and less positive feedback.

ASSESSING EMOTIONAL DEVELOPMENT

Taking a preventive approach to challenging behaviors by designing programs that engage students and teach them new social skills may ward off some challenging behaviors. Others may continue in spite of quality programming. Although the emotional-related behaviors may be obvious, it is important to gather some data to assess the child's emotional development or atypical development and to aid in developing a plan to improve the behavior.

Assessment begins with deciding which behavior is the most challenging and needs immediate intervention. Considerations include whether or not the behavior is harmful to the child or others, how the behavior might interfere with learning or participation in learning activities, and if the behavior will hinder development of positive social relationships. Detailed explanations of behaviors are most helpful at this stage. The second step is to conduct a functional assessment. This involves conducting interviews with parents and others to determine what precipitates the behavior and what the consequences

of the behavior are. An ABC chart of columns can help with observation.

Next is the step of developing hypothesis statements based on behavioral patterns that emerge from the functional assessment information. A support plan follows, with proposed changes to the antecedent events that lead to the behaviors and inappropriate emotional expressions. Finally, professionals can implement, evaluate, and modify the plan. Baseline rates of challenging behaviors and appropriate replacement skills should be noted and later compared.

RISK AND PROTECTION IN EMOTIONAL DEVELOPMENT

Dr. Carolyn Saarni, professor of counseling at Sonoma State University (California) has discussed two rules of emotional display, prosocial and self-protective. With prosocial rules, a child alters his or her displays of emotion to protect another's feelings. In self-protective display, the child masks emotions to avoid embarrassment or to protect himself or herself from potentially negative consequences. Research on which of these self-regulation strategies emerges first is mixed. Throughout a child's life, however, the risks of displaying emotion persist, probably most blatantly in adolescence, when peer pressure works on emotional regulation. Gender also plays a role in the types of emotions children, and adolescents, in particular, feel comfortable displaying. Boys are less likely than girls to express fear in times of stress, for example, for fear of belittlement. For the most part, self-protection and prosocial rules aid in positive emotional development.

RESEARCH ON CLASSROOM STRATEGIES

A framework that promotes positive relationships in the classroom helps prevent and address challenging behaviors. The pyramid model developed by Fox, Dunlap, Hemmeter, Joseph, and Strain in 2003 begins with positive, supportive relationships from parents, teachers, and other professionals. Many professionals agree that students with an emotional disturbance need a structured leaning environment and inclusive schooling. However, data from the Special Education Elementary Longitudinal Study (SEELS) and the National Longitudinal Transition Study-2 (NLTS2), reported in 2006, showed that elementary and middle school students with emotional disturbances tended to spend more time in special education classes than other students with disabilities. The study also showed that 75% of students with emotional disturbances were receiving extra time to complete academic tests. A low percentage were receiving mental health services.

The issue of violence has taken an elevated importance in schools. Concern has been expressed that disci-

pline provisions in the Individuals with Disabilities Education Improvement Act (IDEA), such as the "stay-put" rule and cumulative 10-school-day limit on suspensions would promote school violence by unfairly protecting students with disabilities who exhibit disruptive or violent behaviors. In 2001, the General Accounting Office reported that students with and without disabilities generally were disciplined in the same manner and that IDEA played a limited role in affecting schools' ability to properly discipline students.

EMOTIONAL INTELLIGENCE

The term *emotional intelligence* (EI), first introduced in the 1990s by Peter Salovey of Yale University and John (Jack) Mayer of the University of New Hampshire, refers to how thinking about emotion and integrating emotion into cognitive processes both facilitate and enhance reasoning. Similar to conceptualizations of intelligence, EI

involves the capacity to engage in abstract reasoning, but about emotions in particular. According to the Salovey and Mayer model, there are individual differences in EI, such that individuals who are more skilled at perceiving, using, understanding, and managing emotions are more successful at accomplishing many learning and social tasks than those who are less skilled.

BACKGROUND

In the 1980s, the concept of intelligence was broadening to include an array of mental abilities. Most notably, Howard Gardner, who was primarily interested in helping educators to appreciate students with diverse learning styles and potentials, advised practitioners and scientists to place a greater emphasis on the search for multiple intelligences such as interpersonal intelligence. At the same time, psychologists and cognitive scientists began revisiting the Stoic idea that emotions made humans irrational and self-absorbing; specifically, they considered the alternative viewpoint that emotions could enhance cognitive tasks and social interactions.

Influenced by and active participants in these movements, psychologists Salovey and Mayer began integrating the scientific evidence showing that emotions facilitate reasoning into their theory of EI. Intelligence and emotion, prior to their theorizing, generally identified divergent areas of research.

To understand the relevance of EI, it is important to grasp the critical role emotions play in social interactions and human behavior. Research conducted by Charles Darwin in the late 1800s, Silvan Tomkins in the 1960s, Paul Ekman from the 1970s into the early 2000s, and many others show that the experience and expression of emotion communicates important information about one's relationships. For example, anger signifies that someone or something is blocking one's goal, and fear signifies that someone or something in the environment poses a threat. There is scientific evidence that these emotion signals are universal, that is, broadly understood by cultures around the world. Emotions also appear to be essential to thinking and decision making. Work by neuroscientist Antonio Damasio demonstrates that the ability to integrate emotional information with rational decision-making and other cognitive processes is essential for people to manage their daily lives. Individuals unable to attend to, process, or experience emotion due to damage to specific brain areas (i.e., prefrontal lobe area) make decisions that put themselves at risk.

THE ABILITY MODEL OF EI

The Ability Model of EI proposed by Salovey and Mayer includes four relatively distinct emotion-related abilities:

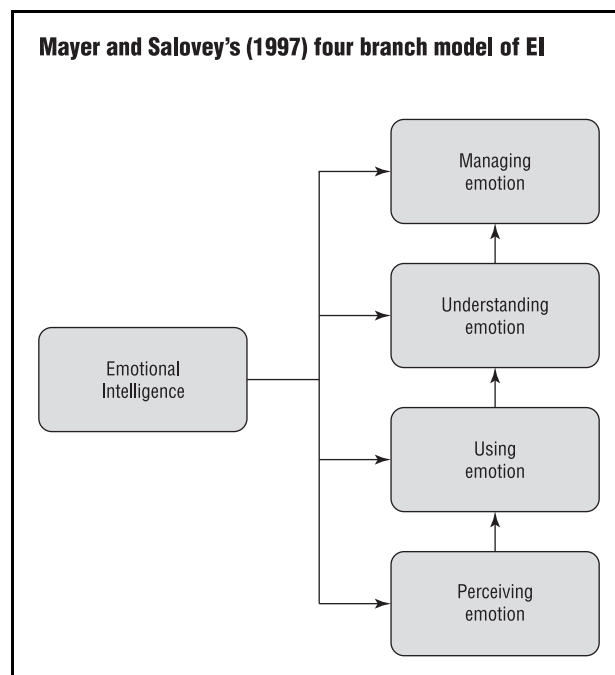

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

perceiving, using, understanding, and managing emotion. Their model is depicted in Figure 1.

Perceiving Emotion. Perceiving emotion involves identifying and differentiating emotions in one's physical states (including bodily expressions), feelings, and thoughts, and in the behavioral expressions of others (such as facial expressions, body movements, voice), as well as in the cues expressed in art, music, and other objects. Persons skilled in perceiving emotion are adept at differentiating between the range of emotion expressions (frustration, anger, and rage) in themselves and in others.

Using Emotion. Using emotion to facilitate thought refers to the use of emotion both to focus attention and to think more rationally, logically, and creatively. For example, positive emotions such as joy and amusement are more useful in stimulating creative thought while slightly negative moods such as sadness are more conducive to engaging in deductive reasoning tasks. Persons skilled at using emotions are better able to generate specific emotional states to carry out a task effectively.

Understanding Emotion. Understanding emotion is the ability to label emotions accurately with language and to know the causes and consequences of emotions, including how emotions combine, progress, and shift from one

to the other (e.g., in some situations, fear and anger combine to create jealousy). Persons skilled in this area have a rich feelings vocabulary and are knowledgeable about what causes various emotions and what behaviors or thoughts may result from their occurrence.

Managing Emotion. Managing emotion is the ability to regulate moods and emotions and involves attending and staying open to pleasant and unpleasant feelings as well as engaging in or detaching from an emotion depending on its perceived utility in a particular situation. To manage emotions effectively, persons must garner the other skill areas of EI: They must be able to accurately monitor, discriminate, and label their own and others' feelings, believe that they can improve or modify these feelings, assess the effectiveness of these strategies, and employ strategies that will alter these feelings. By effectively managing emotions, persons can accomplish situational goals, express socially appropriate emotions, and behave in socially acceptable ways.

EI theory hypothesizes that these four abilities have developmental trajectories. There are various skills within each domain that evolve from more basic to more advanced. For example, in the domain of perceiving emotion, basic skills involve accurately recognizing an emotional expression in others and more advanced skills entail expressing emotions in adaptive ways and discriminating between honest and false emotional expressions in others. EI theory also specifies that the four abilities are hierarchical in structure such that perceiving emotion is at the foundation, followed by using emotion and understanding emotion, with managing emotion at the top of the hierarchy.

The Ability Model of EI is measured by the Mayer-Salovey-Caruso Emotional Intelligence Test (MSCEIT) and the MSCEIT-Youth Version for children. These tests require respondents to perform emotion-related tasks in order to measure their abilities within and across each of the four areas. For example, to assess perception of emotion, respondents examine a photograph of a person's face and indicate the extent to which each of four emotions is present in the expression. To assess managing emotion, respondents rate the effectiveness of different strategies to reduce a particular emotion in order to achieve a specified goal. The correctness of responses is compared to those provided by normative sample and a sample of emotion experts.

OTHER MODELS OF EI

In 1995 the concept of emotional intelligence was made wildly popular by the publication of Daniel Goleman's book, *Emotional Intelligence: Why It Can Matter More than IQ*. In the ensuing years, myriad models of EI were

created. The ability model of EI proposed originally by Salovey and Mayer was published prior to Goleman's book and stands in contrast to other models which incorporate a wide variety of personality traits and other characteristics such as optimism, happiness, and self-awareness. Proponents of these so-called *mixed* or *trait models* of EI (i.e., models that mix abilities with personality and other characteristics) typically use self-report scales instead of performance-based assessments to measure EI (i.e., respondents indicate the extent to which they believe they are able to regulate their emotions as opposed to identifying effective strategies to solve emotion-laden problems). Self-report EI scales in general overlap considerably with personality assessments (i.e., they do not measure a construct significantly distinct from existing personality scales). Responses to self-report EI scales typically do not correspond with performance on the MSCEIT, and MSCEIT scores generally are more predictive of important outcomes than self-report EI scales.

EI AND CLASSROOM LEARNING

The abilities and knowledge areas captured by the EI ability framework contribute to students' academic achievement, ability to maintain quality social relationships, psychological and physical well-being, and later life success. A meta-analysis of more than 250 studies conducted by Roger Weissberg and Joseph Durlak at the Collaborative for Social and Emotional Learning (CASEL) reveals that the average student enrolled in school-based programs that promote emotion and social skills performs significantly better on achievement tests and has better grades than non-participants. Emotionally skilled students, for example, are better able to identify the causes of their anxiety and may anticipate that an upcoming test is causing them to feel distress. To manage the distress, these students are more likely to engage in proactive behaviors such as asking teachers for help in studying and ensuring they have sufficient time and resources to prepare for the exam.

There is ample scientific evidence that the skills of EI are related to social competence (see work by Nancy Eisenberg and by Susanne Denham for examples). Students who recognize emotions in others and understand, label, express, and regulate their own emotions effectively have good social skills, strong friendships, and high opinions from peers. These positive social outcomes enhance academic achievement. For example, compared to others, students with strong friendships feel more comfortable in the school environment, receive better academic support from teachers, get more social support from peers, and develop healthier attachments to school.

The skills of EI also are related to psychological well-being and to anxiety and depression (in the expected

directions). Students with lower EI, especially boys, are more likely to engage in behaviors that put their health and well-being at risk, including drinking, smoking, using drugs, and engaging in violent behaviors. The incidence of anxiety and depression and of these behaviors interferes with learning.

In their research Brackett and Rivers found relationships between EI with teacher ratings of students' leadership skills, study skills, and their ability to adapt to changes. They also found that students with greater EI were less likely to experience (according to teacher evaluations) problems that include aggression, anxiety, conduct problems, hyperactivity, and learning difficulties.

TEACHING EMOTION SKILLS AND KNOWLEDGE IN SCHOOLS

Schools and classrooms provide an ideal place for teaching emotion skills and knowledge. For many children, school is the first opportunity for continued and stable social interactions, and it is difficult for many children to develop their emotion skills solely within the home when, more and more, both parents are working full-time and often have multiple jobs. CASEL researchers contend that "Schools and classrooms in which adults are nurturing, supportive, and caring furnish the best contextual opportunities for social emotional learning programs to be introduced, sustained and effectively provided" (Elias et al., 1997, p. 75).

With their collaborators, Brackett and Rivers have developed a series of programs to teach students how to recognize, understand, and label accurately both their own and others' emotions, appropriately express their thoughts and feelings, and regulate their emotions effectively, as well as to appreciate the significance of these skills in the academic, social, and personal lives. These programs, titled "Emotional Literacy in the Classroom" (ELC) are grounded in theory and scientific evidence, are field-tested, and are integrated easily into existing school curricula. These programs leverage reading, language arts, and social studies instruction to teach emotion knowledge using an innovative multi-faceted approach. The programs complement the regular school-day curriculum and adhere to both state and national standards. The ELC programs, which have been adopted by and tested in school districts across the United States and abroad, address the particular social and emotional needs of students and help create a caring and challenging classroom environment that fosters effective and enduring academic learning. Accompanying professional development and training programs for teachers and administrators provides educators with the skills and support they need to effectively teach emotion knowledge and skills to students.

EPISTEMOLOGICAL BELIEFS

Epistemology is the branch of philosophy that investigates what knowledge is and how people know whether they know something (BonJour, 2002). It addresses questions such as: What is knowledge? How do people know if they really have knowledge? What provides a justification for any knowledge that they have? For example, on what grounds are people justified in believing that electrons have negative charge or that an accused robber is guilty? Are people convinced by sensory evidence, by testimonial evidence, by strong intuitions, or by some other means?

Epistemologists, of course, have developed many ideas about how to answer questions such as these. In recent years, psychologists have become interested in whether people other than philosophers have ideas about what knowledge is and how knowledge is justified. In other words, psychologists have wondered if people have beliefs about epistemological questions (called *epistemological beliefs* or *personal epistemological beliefs*) and whether these beliefs affect in any way their learning or reasoning.

To see why these issues are important, consider the following hypothetical students, both eighth graders learning science:

- Emily believes that the scientific knowledge she is trying to master typically has a very *complex* structure with rich and numerous interconnections. Sharon, on the other hand, believes that scientific knowledge has a very *simple* structure, consisting of lists of unrelated facts.
- Emily believes that people know that scientific knowledge is true on the basis of observational evidence. In contrast, Sharon believes that people know that scientific knowledge is true because the textbook and her teacher say so.
- Emily believes that scientific theories are fallible; she knows that there are often competing theories, and it sometimes takes years to work out which theories explain the observational evidence better. Sharon, however, thinks that there is only one scientific theory on any idea, and this theory is absolutely and forever true.

In summary, Emily and Sharon differ in their beliefs about the *complexity of knowledge*, the *source of knowledge* (observation versus the authority of the teacher and text), the *certainty* of knowledge, and whether there can be (and are) *competing theories* attempting to explain the same data.

Emily's and Sharon's ideas for learning and reasoning in science have several possible implications:

1. When studying cellular processes, Emily expects to find rich interrelations among ideas, and she tries to understand them when she finds them. Sharon, on the other hand, simply tries to memorize each concept separately, never realizing that the processes are interrelated in interesting ways. In this way, beliefs about the *structure* of knowledge can influence learning.
2. When conducting an experiment on seed germination, Emily finds that the seeds sprout and grow for a while even when they are kept in the dark. She realizes that when the textbook says that "plants need sunlight to grow," this must not apply to seeds. She

decides that perhaps seeds contain their own energy for initial growth. Sharon, however, assumes that she did something wrong in her experiment, because she takes her textbook at its word, and the textbook says that plants need sunlight to grow. Thus, beliefs about the *source* of knowledge (observations versus textbooks) affect how students reason about new evidence.

3. When Emily reads a magazine article about conflicting studies regarding the role of carbohydrate consumption on weight control and health, she understands that much more evidence will probably be needed before matters are more fully understood. She decides to adopt a medium-carbohydrate diet, but she is aware that later evidence may make it necessary for her to change her mind. In contrast to Emily, Sharon is sure that her current ideas about the superiority of a low-carbohydrate diet are absolutely correct, because she learned about these ideas on a website written by an important doctor. She is puzzled why a magazine article would not just state the one correct theory. On this topic, it is clear that students' ability to understand competing ideas as well as how they act in response to these ideas can be affected by beliefs about the certainty of knowledge.

These examples illustrate that epistemological beliefs may have powerful effects on learning and reasoning. A growing body of research supports that such effects do exist (Mason & Boscolo, 2004; Qian & Alvermann, 1995; Schommer, 1990; Songer & Linn, 1991).

EMERGENCE OF PSYCHOLOGICAL RESEARCH ON EPISTEMOLOGICAL BELIEFS

Contemporary psychological research on learners' epistemological conceptions has its roots in the work of William Perry (1968/1999), who investigated the development of male Harvard students' ideas about knowledge during the college years. Other researchers, including Mary Belenky, Patricia King and Karen Kitchener, Marcia Baxter Magolda, and Deanna Kuhn have also investigated changes in epistemological ideas over time. This research has generally aimed to make claims about broad, overall epistemological stances expressed by individuals. For example, in Kuhn's scheme (Kuhn & Weinstock, 2002), children move from a realist epistemology (assertions are copies of reality) to an absolutist epistemology (assertions are correct or incorrect facts), and later to a multiplist epistemology (assertions are opinions, and everyone has a right to their own opinion), and finally (in some but not all people) an evaluativist epistemology (assertions are judgments based on weighing arguments on different sides of a question).

In the late 1980s, Marlene Schommer (Schommer, 1990) and others argued for an alternative approach to conceptualizing people's epistemologies. Schommer argued that epistemologies might be separable into independent beliefs. Schommer proposed three beliefs that would be called epistemological beliefs: a belief in how complex knowledge is (ranging from complex to simple), a belief in how certain knowledge is (ranging from highly certain to highly uncertain), and a belief in the source of knowledge (e.g., knowledge coming from authority). These beliefs were independent of each other. For instance, a person could believe in complex but certain knowledge, complex but uncertain knowledge, simple and certain knowledge, or simple but uncertain knowledge.

Methodologically, Schommer advanced an influential way to measure epistemological conceptions. In contrast to developmental work, which had relied principally on interviews and, to a lesser extent, on written, open-ended questions, Schommer developed a questionnaire called the Epistemological Questionnaire. Several different items were intended to measure the same underlying dimension. For example, two of the items that were intended to measure *certain knowledge* were (1) "Truth is unchanging" and (2) "Nothing is certain, but death and taxes." Respondents rated agreement to each statement on a Likert scale.

Other researchers have developed analogous scales tapping overlapping but not identical sets of epistemological beliefs. For example, Barbara Hofer (2000) developed a questionnaire with items that addressed four epistemological beliefs. The questionnaire was also designed so that the questions referred to a specific field. That is, the questions did not refer to knowledge in general but to knowledge in a specific field such as science or mathematics. The first two epistemological beliefs were about the nature of knowledge:

- Certainty. This belief refers to the extent to which the respondent thinks that knowledge is certain versus fallible and subject to change.
- Simplicity. This refers to the extent to which the respondent believes that knowledge is structured and organized in simple ways with a single right answer rather than in more complex ways with more than one right answer.

The third and fourth beliefs address how a person comes to "know" something.

- Source of knowledge. This belief references where knowledge comes from— from oneself (and one's own experiences) or from others (such as the teacher, the textbook writer, or experts in a field).

QUESTIONS TO ASSESS EPISTEMOLOGICAL BELIEFS

Epistemological beliefs have been measured educational psychologists in different ways and for different reasons. One variation depends on how epistemology is understood. This can range from very narrow to extremely broad theoretical concepts.

There are also many methods for measurement that are not necessarily related to one's theoretical understanding of epistemology. These methods vary according to the preference of the researcher, trends in educational research, and the compatibility of the method to the field and/or context.

Some of the qualitative methods have depended on case studies in which a general question such as: "What stands out to you about the year so far?" is posed to a sample of students. In other quantitative instances, researchers measure specific factors in surveys such as, "belief scales," where students indicate, on a scale of one to five, how much they agree with the statement: "Hard work can increase one's ability to do math."

The context of each study provides another degree of precision. Epistemological beliefs are researched in subject or grade specific contexts, from comparative and multi cultural perspectives, and within discourse of race, class, and gender. This large variety of subject matter denotes the especially broad and important nature of the study of epistemological beliefs in education and beyond.

Samuel Rocha

- Justification of knowledge. Closely related to the source of knowledge, this belief is about the kinds of justifications that are offered in support of knowledge. Justifications might be on the basis of personal experience or the authority of experts.

Other researchers have used items from these scales and have developed their own items to construct new measures.

Though inspired by the philosophical literature, research by psychologists and educational psychologists on epistemological beliefs has not been tightly linked to the philosophical literature. There are relatively few citations of the epistemological literature in psychological

and educational articles about epistemological beliefs. There has been somewhat more connection to the philosophical literature by researchers in the epistemological development tradition, especially in the seminal work of William Perry.

In a 2005 study Clark Chinn and Ala Samarapungavan (have argued that closer attention to philosophical research would suggest many other kinds of epistemological beliefs that could be explored by researchers. For example, psychologists have not explored people's beliefs about social processes of knowledge construction (e.g., are processes such as peer review or interactive argumentation conducive to arriving at true ideas?) or people's beliefs about evidence (what exactly counts as evidence? How should one respond to anomalous evidence?)

EPISTEMOLOGICAL BELIEFS VERSUS BELIEFS ABOUT LEARNING

One issue that has arisen with respect to measures of epistemological beliefs is the need to distinguish between epistemological beliefs and beliefs about learning. Barbara Hofer and Paul Pintrich (1997) argued that researchers have sometimes confused these two related but distinct sets of beliefs. An epistemological belief is a belief about the nature of knowledge or how one comes to believe that it is knowledge. A belief about learning is a belief about how people come to understand and remember ideas regardless of whether they believed them or not. For example, the belief that "knowledge is complex" is a belief about the nature of knowledge but says nothing about how people learn that knowledge. In contrast, the belief that one can learn ideas quickly is not a belief about what knowledge is or how one comes to know or believe it, but rather a belief about how one comes to *learn* the ideas. Indeed, one can learn something which is not viewed as knowledge at all (e.g., one can learn about astrology while believing it to be bunk). One can believe that knowledge is justified on the basis of observational evidence collected by experts (an epistemological belief) yet believe that the best way to learn that knowledge is by having a teacher explain it quickly (a learning belief). Learning is about understanding and remembering. Epistemology is about the criteria for deciding that something is true.

RESEARCH ON EPISTEMOLOGICAL BELIEFS

During the growth of research on epistemological development and epistemological beliefs by educational and developmental psychologists, a second body of research on epistemological beliefs was being conducted by science educators. Most science educators have characterized their research as investigating students' beliefs or ideas about the *Nature of Science* (NOS). Research on

NOS has been growing rapidly since the 1970s and 1980s. Two figures important in inspiring research on NOS were Richard Duschl and Norman Lederman. Duschl made a compelling claim that work by philosophers of science was highly relevant to many aspects of science education; he argued that science educators should align their ideas about the goals and practices of science with what was being learned by philosophers and historians of science. Science educators have responded to this call by investigating the understanding of NOS by both scientists and by students. Science educators have also linked their work more explicitly than educational psychologists have to the philosophical literature, especially to the work of Thomas Kuhn (1922–1996).

Research on students' understanding of NOS has, as one would expect, focused on epistemological issues related to science. The VNOS (Views of Nature of Science Questionnaire) was developed by Lederman and has been since refined by a number of others, including Fouad Abd-el-Khalick. In its most recent version, a few of the questions are:

- What makes science different from other disciplines of inquiry (e.g., religion, philosophy)?
- Does the development of scientific knowledge require experiments? Why or why not?
- After scientists have developed a scientific theory (e.g., atomic theory, evolution theory), does the theory ever change? Why or why not? Give examples.
- Is there a difference between a scientific theory and a scientific law? Give examples.
- Science textbooks often represent the atom as a central nucleus composed of protons (positively charged particles) and neutrons (neutral particles) with electrons (negatively charged particles) orbiting the nucleus. How certain are scientists about the structure of the atom? What specific evidence do you think scientists used to determine what an atom looks like?

These questions are centered around what science is, whether scientific knowledge changes, what scientific knowledge is based on (e.g., experiments), and so on. Other questions address how social and cultural values influence science. Another frequently used interview protocol has been developed by Carol and colleagues (Smith, Maclin, Houghton, & Hennessey, 2000).

Interestingly, at about the same time that educational psychologists began to rely less on interview measures and more on written questionnaire measures of epistemological beliefs, science educators moved in the opposite direction. Whereas early investigations of students' understanding of

NOS tended to use questionnaires, more recent work has favored interviews and open-ended written questions of the sort presented above.

INFLUENCES OF EPISTEMOLOGICAL BELIEFS ON LEARNING AND REASONING

Most researchers would probably argue that promoting more sophisticated epistemological beliefs is a worthy educational goal in its own right. This is particularly true of science educators, as national and state standards explicitly say that part of learning science is coming to understand the nature of science. Most researchers would also agree that developing more sophisticated epistemological beliefs can also benefit other aspects of learning. A large research effort has been devoted to investigating correlations between epistemological beliefs and performance on learning and reasoning tasks. Although a comprehensive summary of findings is beyond the scope of this entry, here are a few typical findings: (1) Students who believe that knowledge is certain write essays that reach unqualified conclusions, even when there is evidence supporting different viewpoints, as well (Schommer, 1990). (2) Students who believe that knowledge consists of ideas that are interconnected (rather than a disconnected series of facts) are better able to understand texts that present alternative positions on controversial ideas (Kardash & Scholes, 1996). (3) Students with more sophisticated epistemological beliefs were better able to learn from an inquiry-based learning environment (Windschitl & Andre, 1998).

These findings should not be interpreted as showing that there are always strong relationships between measure of epistemological beliefs and measure of learning and reasoning. Some have found little relationship, for example, between reasoning and beliefs about the nature of science, and students who exhibit strong progress in reasoning better may show no gains at all in epistemological beliefs (Sandoval & Morrison, 2003). In addition, correlations between epistemological beliefs and measures of learning and reasoning are often relatively low.

HOW PEOPLE FORM EPISTEMOLOGICAL BELIEFS

Many researchers investigating learners' epistemologies have proceeded on the assumption that people do in fact have at least tacit beliefs about knowledge that they can express. Other researchers have questioned this assumption. David Hammer and his colleagues (Hammer & Elby, 2002, 2003) are among those who have argued that most people (other than philosophers) probably do not think about knowledge at all. On the other hand, even if people do not have actual beliefs about knowl-

edge, they do make decisions about what counts as knowledge and what they believe. These decisions are guided by epistemological commitments which are wholly tacit, and which cannot be readily expressed. Alternatively, one can view people as engaged in epistemic practices even if they do not have explicit epistemological beliefs. The term *epistemic* indicates that an activity is oriented to deciding what to believe and why to believe it. A child who decides that bugs have six legs because she has just picked up a bug and counted the legs has engaged in an epistemic activity of forming a belief that bugs have six legs on the basis of her personal observations.

People *do* form beliefs, and by examining the basis on which they form beliefs, researchers can identify their epistemological commitments or epistemic practices. Ala Samarapungavan (1992) conducted a study in which she assessed children's epistemological commitments by observing the theory choices they made. She gave children different theories to consider and different configurations of evidence bearing on those theories. She found that even seven year olds preferred logically consistent to logically inconsistent theories. They also preferred theories that explained more evidence (as opposed to less evidence) and theories that were not inconsistent with any evidence. Through this study, Samarapungavan was able to show that even young children share some of the epistemological commitments often attributed to scientists—a preference for simplicity, consistency with the evidence, and coverage of the broadest possible scope of evidence.

DOMAIN SPECIFICITY OF EPISTEMOLOGICAL BELIEFS

Researchers interested in personal epistemologies have investigated the extent to which epistemological beliefs and epistemic practices are domain-specific. A domain-specific belief is one that is limited to a particular domain (such as mathematics, physics, and so on). For instance, a person might believe that knowledge is certain in math but not in other disciplines. A domain-general belief is one that applies generally to all or many domains. A person who believes that all knowledge in all domains is certain has a domain-general belief.

Researchers have found evidence that epistemological beliefs are domain-specific. For example, Hofer (2000) compared undergraduates' beliefs about knowledge in science with their beliefs about knowledge in psychology. The undergraduates believed that knowledge was more certain and more attainable in science than in psychology. Knowledge in psychology was justified on more personal bases than knowledge in science, which was viewed as based more on authority.

Hammer and his colleagues (Hammer & Elby, 2002, 2003; Rosenberg, Hammer, & Phelan, 2006) have argued

for a much more radically contextual view of personal epistemologies. They argue that epistemologies shift very rapidly from one context to another. For instance, students who are working in a science class may at one moment view knowledge about the rock cycle as *propagated stuff* (information told to them by a textbook or a teacher) consisting of meaningless, isolated facts, and one or two minutes later, the same students working on the same topic may shift dramatically to viewing the same knowledge as *fabricated stuff* (ideas that they are creating themselves) composed of meaningful ideas that they are trying to make sense of. Radical shifts in epistemic practices can be triggered very quickly by shifts in environmental cues. In this view, people do not have stable epistemologies at all.

Research on personal epistemologies is thriving, with alternative theories being advanced and tested and a new measurement tools being developed. The steady increase in the number of researchers investigating this topic suggests that ideas about epistemologies and epistemological development will play an important role in theorizing about how people learn and reason.

Clark A. Chinn

EPISTEMOLOGICAL DEVELOPMENT

Epistemology, historically the province of philosophers, concerns the origin, nature, limits, methods, and justification of human knowledge. From a psychological perspective, *personal epistemology* refers to individual conceptions of knowledge and knowing and how people develop, interpret, evaluate and justify knowledge (Hofer & Pintrich, 1997, 2002). Knowledge and knowing appear to develop in a patterned sequence across the life span. Understanding the trajectory of epistemological development and how it relates to learning and education can be useful for teachers, students, and educational researchers.

TRAJECTORY OF EPISTEMOLOGICAL DEVELOPMENT

Research on epistemological development began with the work of William Perry, who conducted longitudinal interviews with several classes of Harvard students beginning in the mid-1950s, asking them a set of open-ended questions at the end of each academic year. Perry was interested in how individuals responded to the intellectual and moral relativism encountered in a pluralistic university. At the outset of his research he expected that the differences he had observed in undergraduates' views about learning and teaching were likely to be related to personality. For example, a dichotomous view of knowledge as right or wrong and to be transmitted from an all-powerful authority would be evidence of an authoritarian personality, a construct of considerable interest to psychologists in the era following World War II. What he and his research staff found, however, was that the way in which students thought about knowledge and knowing changed during the college years, and most important, this change occurred in an ordered and predictable sequence of intellectual and ethical development.

The trajectory that Perry and his colleagues identified suggested that over time individuals transformed their views of knowledge and knowing from a position of dualistic thinking (a world viewed in absolutist polar binary terms of black and white, right and wrong) toward more contingent, relativistic thought. Thus the perception of knowledge as objective and certain was not a personality characteristic, but something malleable and apparently influenced by education. Perry's research resulted in a nine-point scheme of development that became the precursor for a significant body of research and the foundation for a wide range of ideas about educational implications of epistemological development.

Other similar schemes of intellectual development with epistemological components followed, all based on Perry's work. These models include reflective judgment, developed by Patricia King and Karen Kitchener; women's ways of knowing, developed by Mary Belenky, Blythe Clinchy, Nancy Goldberger, and Jill Tarule; and epistemological reflection, developed by Marcia Baxter Magolda. Additionally, Deanna Kuhn, in her research on the skills of argument, outlined a set of epistemological assumptions that further refined into a pattern of epistemological development with colleagues Richard Cheney and Michael Weinstock. Overall, each of these approaches involves a stage-like progression of from three to nine positions, but the components and the trajectory are remarkably similar.

Typically, individuals in any of these studies, primarily of college students and adults, are perceived as beginning with absolutism, a worldview marked by dual-

ism and certainty: knowledge is black or white, right or wrong, highly certain, composed of discrete facts, and handed down from authorities unquestioningly. This position is modified as individuals come to recognize the legitimacy of other viewpoints. A midpoint on most schemes is characterized by multiplism, the idea that one opinion is equally valid as any other, that knowledge is highly uncertain, and that there is no agreed-upon means for justification. Advancement from this subjective state to a position of evaluativism (or commitment within relativism, as Perry called it) is marked by a growing realization that there are means for justification of various positions and that this enables an individual to assert some positions with confidence even if knowledge is evolving and contingent. Individuals who see the world from the upper levels of development are able to evaluate expertise, reconcile theory and evidence, provide support for their claims, and re-evaluate those claims in the light of new evidence.

EXPANDING THE SCOPE OF EPISTEMOLOGICAL DEVELOPMENT

Although the original scheme of development was based on Perry's study of males at an elite post-secondary institution in the United States in the 1950s and 1960s, the research was later extended to include broader populations: females, older adults, individuals not attending college, children and adolescents, and individuals in diverse cultures. One particularly important expansion of Perry's work in the decades that followed was the inclusion of women in the research sample and more deliberate attention to the perceptions of women, as in the women's ways of knowing study, or on gender-related patterns in the epistemological reflection research.

Belenky and her colleagues determined it important to study women only, as a means of understanding how women in particular approached knowledge and knowing. One of their contributions was in their attention to women's perceptions of the source of knowledge whether knowledge was viewed as external and received, entirely internal, or constructed in interaction with the environment. In the fourth level of a 5-point scheme, called procedural knowing, individuals may be either separate knowers who are detached, critical, and skeptical, or connected knowers, who are empathic and trusting, valuing understanding over judgment. The final stage, constructed knowing, involves integration of these two approaches, a more complex recognition of the relation between the knower and the known and a tolerance for contradiction and ambiguity.

The epistemological reflection model, derived from longitudinal interviews of both male and female college students, suggests that some patterns of knowing may be

gender-related but not gender-specific, as had been hypothesized by the authors of the women's ways of knowing study. At various stages in a five-point scheme that culminates in contextual knowing, women are more likely than men to be described as received knowers rather than mastery knowers, interpersonal rather than impersonal, and inter-individual rather than individual.

Such findings about gender-related patterns may need to be placed in the historical context of research conducted primarily in the 1980s. Little work in the 2000s has been done to assess the continuing validity of gender-related patterns of epistemological development and to determine whether changes in child-rearing or increased successes of females in education at all levels may have had an influence on epistemic worldviews. Continued research is needed in this area, and any application of gender-specific findings from these early studies should be made with caution. As with any group-level findings, generalizing from group differences to the individual is not recommended.

In addition to expanding epistemological research to include women, researchers have pursued epistemological development prior to the college years, an area that as of 2008 also needed further study. The early research on college students posited a trajectory beginning in absolutism, which implied that younger individuals simply viewed the world in absolutist terms until their beliefs were challenged in college. Surprisingly little longitudinal research has been conducted prior to college, but researchers such as Michael Boyes and Michael Chandler, who have assessed epistemological development in adolescence, have identified parallel stages similar to those in the college years. Chandler and others have thus raised questions about whether development might be recursive: Perhaps individuals move through the stages repeatedly, with enhanced understanding at each passage. In general, research on adolescence would indicate that high school students can exhibit post-absolutist perspectives, but more work is needed to distinguish this from the more nuanced perspectives of advanced college students. An established trajectory of epistemological development prior to the college years was as of 2008 not available.

Research from the late 1990s and early 2000s on young children began to illuminate the origins of epistemological development and to connect it to cognitive development. Very young children appear to begin at a state of egocentric subjectivity, a period in which the only perspective available is the knower's own. The attainment of theory of mind, a cognitive development between 3 and 5 years of age that involves a growing awareness of the beliefs, desires, and intentions of others, creates the potential for advancement toward an early sense of epistemic objectivity. Typically assessed through false belief tasks, theory of mind allows a child to know that another

individual can believe something erroneously. This cognitive awareness of multiple perspectives on knowing, and of the sense that one person can be right and another wrong, provides the foundation for absolutism.

Other researchers have been interested in understanding whether the developmental trajectory evidenced in U.S. studies is consistent in other cultures, or whether it might be an artifact of western education. In one cross-cultural study of Perry's scheme, Li-Fang Zhang found that students in Beijing, unlike those in the United States, became more dualistic during their college education, perhaps as result of an educational system that at the time of the study permitted few opportunities for individual decision making. Results of this and other studies suggest the need for sensitivity to cultural context and for more explorations of the interaction between educational environment, cultural context, and epistemological development.

DOMAIN SPECIFICITY

Much of the research on epistemological development is based on a presumption that a general cognitive framework guides one's views of knowledge and knowing across domains. Thus an individual who believes that there is one right answer and that authorities are the sole source of knowledge would believe this regardless of the area in question. By contrast, research on epistemic beliefs has been examined both generally and in regard to specific disciplines, such as math, science, or history. Students have been found to hold differing beliefs about disciplines, for example, that knowledge in chemistry is more certain than knowledge in psychology, as well as beliefs specific to disciplines, for example, that knowing history means learning dates. Math and science educators have extensively pursued an understanding of students' epistemic beliefs within these particular disciplines, exploring such conceptions as the nature of science. This area had as of 2008 seldom been investigated developmentally, however, although Ala Samarapungavan, Erik Westby, and George Bodner found that the epistemic development of chemistry students was influenced by aspects of their research experience and engagement with expert researchers.

Within the paradigm of epistemological development, some researchers began to explore domain differences, but little of this research focused on disciplines. In one such report, King and Kitchener (2004) noted in their overview of research on reflective judgment that there is a high rate of consistency in the use of epistemic assumptions in reasoning about ill-structured problems, regardless of domain. Other research on domain differences in epistemological development addressed domains not as disciplines, but in regard to judgment domains,

such as taste, morality, aesthetics, values, or facts. In their study of individuals from second grade through adulthood, Kuhn, Cheney, and Weinstock found that individuals can be at different epistemological levels depending on the domain, with individuals, for example, accepting multiple viewpoints in regard to personal taste before they accept them in regard to objective facts. The movement from multiplism to evaluativism is more likely to occur first in regard to objective facts, where warrants for claims begin to supersede individual opinions.

Domain differences have also been explored in studies of young children by Cecilia Wainryb and her colleagues, who found that even 5-year-olds display evidence of relativism in some domains more than others. Children can be expected at a fairly early age, for example, to know and accept that a friend prefers a different flavor of ice cream but can be quite certain that hitting is wrong. What this continued line of research suggests is both that epistemological development varies by judgment domain and that it is possible for aspects of multiplism to occur much younger than might have been predicted in the pioneering studies of college students.

METHODS OF INVESTIGATING EPISTEMOLOGICAL DEVELOPMENT

The original research on epistemological development was inherently phenomenological, with open-ended interviews that prompted meaning-making on the part of the student being interviewed. Perry, for example, began his end-of-semester interviews by asking "What stands out for you about this year?" Some of the researchers who followed Perry continued to use open-ended interviews, and others have posed ill-structured problems as a means of eliciting epistemological assumptions. For example, reflective judgment interviews involve responding to questions about issues such as the dangers of chemical additives in food, e.g., "Can you ever know for certain that your position on this is correct? How? Why not?" and "How is it possible that experts in the field could disagree about this subject?" Similarly, research on the epistemological aspects of argumentation employed questions about the certainty and justification of knowledge on topics such as reasons for criminal recidivism and other topics for which there are not likely to be simple, agreed-upon answers. Other studies on epistemological development involved asking individuals about the possible causes for a fictitious war or required a simulation of juror reasoning. Research interviews with young children, particularly in regard to domains of judgment, have been more likely to involve puppets and other props or vignettes with illustrated depictions of the scenario involved.

Interviews that require individuals to respond to ill-structured problems are called production tasks, as the

interviewee is asked to produce a response. The transcribed protocols that result are complicated to score and typically require trained raters. Although this method provides rich data and affords a complex understanding of participants' thinking, it is also an expensive and time-consuming approach. The need for measures that can be administered and scored more easily led to the design of written instruments, typically aimed at providing some means for scoring developmental level. These are more likely to involve recognition tasks, in which individuals indicate the similarity of prepared responses to their own understanding. For example, participants indicate how similar a statement such as the following is to their own thinking: "It is my perspective that what researchers conclude is just their own opinion." These instruments make it possible to conduct larger studies more quickly, but there is also concern about validity, reliability, and reductionism, as complex developmental phenomena are reduced to recognition of simple statements, potentially inflating individual scores.

EDUCATIONAL IMPLICATIONS

Epistemological development has significant implications for the ways individuals consider and approach knowing and learning in a wide range of contexts, across the life span. Individuals often need to make considered judgments on a wide range of issues from personal health to global environmental concerns, and these judgments typically require weighing of evidence and evaluation of competing knowledge claims. Yet research on epistemological development suggests that the skills required to do this, evidenced in the position of evaluativism, are not all that common and that adults in the United States are more likely to be either absolutists, convinced one position must be right, or, more often, multiplists, basing decisions on personal judgments and viewing opinions as equally valid. Kuhn and others have argued that epistemological understanding matters and that preparation of an educated citizenry requires more attention to this process within the educational system at all levels.

A number of researchers who work within the developmental tradition assert that the higher levels of epistemological development are consistent with the skills of critical thinking and adaptive complexity. Thus epistemological development has been viewed by some as one of the aims of education and as a potential outcome measure for a college education. Accordingly, a number of studies have evaluated students' progressions toward higher stages of the various schemes, particularly during the college years. Longitudinal interview studies conducted in college and in some cases beyond suggest that college does have a small but measurable impact on epistemological development and that graduate school

may advance this further, particularly in terms of higher stages of reflective judgment. Cross-sectional studies generally show a correlation between education and level of development and also between expertise and epistemological development.

Epistemological stance can also lead students to have different views of education, classroom tasks, and expectations of teachers. For example, absolutists would be likely to want teachers to provide objective truth, multiplists might have difficult understanding how teachers could make the judgments they do, and evaluativists would expect substantiated support for various positions. Educators' awareness of these general schemes can help them understand student reasoning and responses to particular aspects of education and to enable them to provide support for developmental transitions. The relation between education and development can also be viewed as reciprocal, with individuals interpreting learning through a current lens that is also being transformed in the process.

Overall, educators may wish to help students make a progression toward competence in evaluating multiple truth claims and understanding how knowledge is constructed, supported, and evolving. Research on epistemological development suggests that teachers need to attend to thinking skills and cognitive development as well as the mastery of content. Teachers can provide students with opportunities to discuss ill-structured problems, for example, and to recognize that not all problems have one right answer. Educators might also structure assignments so that students learn to gather support for particular positions, consider opposing viewpoints, coordinate theory and evidence, and evaluate expertise and authority. These are challenging tasks, but they are critically important in helping students develop intellectual skills.

ERIKSON, ERIK

1902-1994

Erik Erickson (1902-1994), noted psychoanalyst and student of Anna Freud, is not a figure who immediately comes to mind when one thinks about the great contributors to understanding of the psychology of classroom learning. Erickson stands out among Freudians as one of the first to use a psychoanalytic perspective with children and to develop play therapy techniques for counseling. His work with World War II U.S. veterans experiencing shell shock helped solidify his understanding of the mechanisms of identity, and his famous 1968 publication, *Identity: Youth in Crisis*, helped explain the generational, social, and racial tensions of his day. The central question of his work had to do with identifying factors that affect personality.

Erik Erikson in his home study, March 4, 1975. TED STRESHINSKY/TIME & LIFE PICTURES/GETTY IMAGES.

ERIKSON'S CONTRIBUTION TO THE FIELD

Erikson's contribution to the field of educational psychology may be subtler than the mainstays of school-related research pertaining to learning and achievement. It lies not in the products of schooling, but in helping people understand the importance of interactions between teachers and students.

Erikson's work is likely to be known in many areas outside educational psychology, and any casual student of identity is familiar with his theory. His description of identity development and the mechanisms associated with this interpersonal milestone are familiar to most teachers of adolescents either through personal experience or through observation. In this context, Erikson made two important contributions regarding classroom interaction: (a) recognition that adolescence is a time when individuals search for the standards and truths that really matter, and (b) adults, and especially teachers, play an important role in adolescents' identity development. These two contributions provide insight into effective

strategies teachers can use when interacting with their adolescent students.

IDENTITY AND STANDARDS

The first contribution has to do with how Erikson understood ego and identity. Erikson agreed with Sigmund Freud's triadic model of the human psyche (id, ego, superego). Unlike Freud, who focused on the conflict between id and superego and the mediating role of the ego, Erikson described the work of the ego in terms of differentiating itself from the superego. In Erikson's view, each stage of psychosocial development, from birth to old age, involves some form of differentiation of self from others.

Differentiation of the ego has to do with the degree to which a person is what others tell him versus how much a person controls what he is. During the stage of psychosocial development associated with adolescence, the work of identity formation involves examination of social standards or values and selection of those that the adolescent believes are truly important. If choices are not actively made, the person's identity is in a state of foreclosure. If adolescents are actively involved in searching, but have not yet chosen standards, identity can be described as being in a state of moratorium, the condition most often associated with adolescence.

ROLE OF ADULTS

Given Erikson's perspective on identity development, the second important contribution is his description of the role that adults play in adolescents' identity development. This description is particularly relevant for educators. During the time of adolescent moratorium, adults can facilitate identity development in two ways. The first way is by being a "sanctioner of capabilities." (Erikson, 1968, p. 87) To adolescents, adults are the bearers of society's standards. In this generational role, adults should be clear about the standards they hold, exhibit behaviors consistent with stated beliefs, and use those standards to judge adolescents. By using society's standards to judge, adults communicate with adolescents about their capabilities and help clarify their selection of standards. Judged in an honest fashion, adolescents learn about their capabilities for adult roles. The second way adults assist with identity development is by providing an environment in which identity can be explored. During the time of moratorium, adolescents need opportunity to scrutinize society's standards and try on identities in a setting that does not impose an uncritical choice.

IDENTITY DEVELOPMENT AND TEACHER STUDENT INTERACTIONS

Adults, and especially teachers through their generational role, can contribute to adolescents' identity development

by being sanctioners of capabilities and by providing a safe environment in which adolescents can deal with their identity crisis. In his understanding the dynamics of schools and classrooms, Erikson believed these two actions are keys for effective interactions between teachers and adolescent students. Teachers who are honest about their beliefs, consistent in their actions, and who find capabilities in adolescents to sanction are, according to Erikson, more likely to sustain adolescents' initiative and elicit their cooperation in academic matters.

ETHNIC IDENTITY AND ACADEMIC ACHIEVEMENT

This entry provides an overview of the concept of ethnic identity, with a focus on its relevance for ethnic minority adolescents' academic development. Researchers and educators increasingly have recognized the important role of race-related beliefs and experiences in the academic achievement of ethnic minority children and adolescents. Various explanations have been offered to explain ethnic minority achievement and underachievement, and most implicate the role of youths' *ethnic identity* beliefs, or their self-constructed definitions of the relevance and meanings associated with being a member of their ethnic group. Ethnic minority groups face many social and

structural risks and challenges in the United States, and a stronger identification with an ethnic minority identity has been related to perceiving more ethnic group barriers and discrimination and having a higher awareness of group stigma and stereotypes. Because of this, some have suggested that a stronger ethnic group identity necessarily places youth at risk for decreased academic engagement. However, there is more support from emerging theory and research that a strong, positive sense of racial identity relates to more positive achievement values and may help adolescents maintain positive academic motivation and engagement when they perceive group barriers or have negative race-related experiences. The literature reviewed in this entry suggests a number of implications for education. One is that schools can play important roles in supporting youths' development of a positive sense of ethnic identity. Furthermore, moving away from a "colorblind" approach and recognizing youths' distinct ethnic identities as potential assets can improve schools' and educators' abilities to create truly inclusive settings.

ETHNIC IDENTITY: DEFINITION AND SIGNIFICANCE

During adolescence, individuals begin to construct a general sense of their identity, or their personal definitions of who they are, what is important to them, and appropriate ways to think and behave. During this period, youth also differentiate their various social identities, the self-constructed definitions of who they are in relation to the social groups to which they belong. A sense of ethnic identity becomes salient for many ethnic minority adolescents as they explore the significance of their ethnic group membership in defining who they are (Spencer & Markstrom-Adams, 1990; Phinney, 1990). Ethnic identity has multiple components, including individuals' views of the importance of their ethnic group to their self-definitions, the meanings they attach to their ethnic group, and their thinking about how their ethnic group affects their position in society. Thus, ethnic identities are descriptive (e.g., "I am a Mexican American"; "I am an African American"), affective ("I feel positively about being an African American"; "I think others regard my ethnic group positively"), as well as prescriptive ("I know how Chinese Americans act"; "I know how African Americans act"). Adolescents' understandings of the meanings of their social identities influence their adaptations and responses within domains in which those identities are salient. Because race and ethnicity often are salient in the domain of education, adolescents' ethnic identities may be particularly relevant in shaping how youth interpret and respond to their social and classroom contexts at school.

ETHNIC IDENTITY DURING ADOLESCENCE

Relative to younger children, adolescents have more highly developed cognitive abilities related to understanding themselves and their experiences in more complex, abstract, and indirect ways, and this period also involves intensification of particular social-cognitive attributes, e.g., heightened awareness of how they are viewed by others. Thus, they become more cognizant of the relevance of race and ethnicity in society and have a higher likelihood of perceiving experiences in terms of race and ethnicity (Spencer, Dupree, & Hartmann, 1997).

In addition to individual differences in social cognition, cultural, structural, and social influences during adolescence may affect the development of ethnic identity beliefs. Information youth appraise from interactions in their primary social contexts influences how they develop understandings of themselves in relation to the social groups to which they belong (Harter, 1990; Spencer, Dupree, & Hartmann, 1997). Adolescents' ethnic identity beliefs derive in large part from their understanding and internalization of socialization messages they receive from their families and communities about their ethnic group's history and values (Hughes & Chen, 1999). Other important influences on ethnic identity development include the social and economic opportunities and constraints youth perceive as available to members of their group in their families and communities. Finally, adolescents' increased exposure to personal and societal racism (Garcia Coll et al., 1996; Greene, Way, & Pahl, 2006) influences their ethnic identity development.

ETHNIC IDENTITY AND ETHNIC MINORITY ACADEMIC ACHIEVEMENT

Academic engagement requires linking one's personal identity to the roles of student and learner (Garcia & Pintrich, 1994), showing sustained curiosity and interest in class, and displaying intense efforts in learning tasks (Connell, Spencer, & Aber, 1994; Skinner & Belmont, 1993). Adolescents' academic engagement has been linked to social identities that are made salient in the academic domain (Garcia & Pintrich, 1994). The academic domain is one in which race often is salient for many ethnic minority adolescents. For instance, entry into secondary schools is associated with increased racial cleavage, social comparison, and heightened salience of racial and ethnic stereotypes (Fisher, Wallace, & Fenton, 2000). Thus, it is likely that minority adolescents' levels of academic engagement are influenced, in part, by their ethnic identity beliefs. Theory and research suggests that ethnic identity may serve as a risk factor for lower academic motivation and achievement as well as promote

academic motivation and achievement. The risk and promotion approaches are described below.

RACIAL IDENTITY AS AN ACADEMIC RISK FACTOR APPROACH

Within several well-known theoretical models, ethnic minority identity has been posited to place individuals at risk for decreased academic engagement through the influence of their heightened awareness of the negative status of their racial group in society (e.g., Aronson, 2002; Fordham & Ogbu, 1986; Fordham, 1988; Mickelson, 1990; Steinberg, Dornbusch, & Brown, 1992). The Cultural-Ecological framework of ethnic minority achievement offered by Fordham and Ogbu (1986), for instance, asserts that because African American populations immigrated to the United States under conditions of oppression and opportunity constraint, they developed a collective group identity that rejects institutions that are dominated by the oppressive mainstream culture, including the American educational system. As a consequence, youth's identification with a Black identity came to entail a rejection of a pro-achievement orientation, including attitudes and behaviors associated with being successful in school.

Fordham (1988) expanded on this framework, positing that sustained school success for high-achieving African American students entails minimizing their connectedness to their racial identity in exchange for mainstream attitudes and values that are better aligned with an academic identity, a process termed as becoming "raceless." A similar theme within educational research is the notion that having a "colorblind" perspective is the best way to ameliorate racial group differences in achievement. Within the education field, the majority of teachers are white, from backgrounds that differ from those of their students of color, and often have had limited multicultural training (Ford & Harris, 1996). A common ideology among teachers entering their professions and classrooms is that it is best to simply not see race or racial group differences at all but view students only as individuals (Markus, Steele, & Steele, 2000; Rousseau & Tate, 2003). However, the underlying presumption is that minority youth must de-emphasize their ethnic/cultural backgrounds in order to develop a positive academic identity and emphasize thinking and acting in ways more consistent with White middle-class norms (Delpit, 1995; Ladson-Billings, 1995; McAllister & Irvine, 2000).

Other theoretical perspectives viewing ethnic identity as a risk factor for achievement have focused on the stigma associated with identifying with an ethnic minority group in the United States. This work suggests that African American and Hispanic youth disidentify with school and academics because the academic domain is one in which their ethnic group is regarded negatively

(e.g., Crocker & Major, 1989; Osborne, 1997). While this coping strategy is theorized to protect individuals' self-concept from the negative impact of perceiving group-based discrimination and devaluation, it inhibits the motivational attitudes and behaviors that lead to good school performance. Similarly, stereotype threat theory posits that African American students' academic underperformance result from fears or apprehensions around supporting racial stereotypes related to intellectual ability, and, over time, these threat experiences lead to less personal identification with academics and engagement in the learning process (Aronson, 2002; Steele, 1997). Implicit across these perspectives is that individuals who perceive societal discrimination or stigma for their ethnic group disengage with the educational process, and those who emphasize their ethnic minority identity are particularly vulnerable to the negative effects of this discrimination and stigma on academic engagement.

LIMITATIONS OF THE ETHNIC IDENTITY AS RISK APPROACH

A major limitation of the ethnic identity-as-risk approach to understanding ethnic minority academic achievement is that there is very little empirical evidence in support of the major assertions of the approach. First, there have been few studies directly assessing the relationship between ethnic identity attitudes and academic engagement in African Americans. The few studies that have been used to support the approach do not directly address the question of whether identifying with one's race and perceiving racial barriers explains individual differences in African American students' levels of academic engagement. For instance, in the widely cited ethnographic study of urban African American high school students (Fordham & Ogbu, 1986), although low-achieving students perceived particular behaviors associated with school success e.g., spending time in library studying, reading and writing poetry, being on time as inconsistent with their personal identities, students were not asked about their racial identities nor did the youth mention ethnicity or race when discussing their academic identities (e.g., youth connected pro-achievement behaviors to being a nerd or "brainiac," not necessarily as being inconsistent with a Black identity).

Other evidence used in support of the risk approach include studies showing smaller associations between African American adolescents' self-concept and their academic grade performance relative to other ethnic groups (e.g., Demo & Parker, 1987; Osborne, 1997) and lower academic task performance for ethnic minority college students for whom racial stereotypes are made salient (e.g., Steele & Aronson, 1995). None of these studies, however, directly assessed youths' ethnic identity beliefs and thus are unable to fully demonstrate the presumed links between ethnic identity and academic engagement.

ETHNIC IDENTITY AS PROMOTING ACADEMIC ACHIEVEMENT

Although the identity-as-risk approach has received a great deal of attention, ethnic minority identity also has been conceptualized as an important psychologically protective set of beliefs that individuals have developed to buffer against the impact of racial discrimination and stigmatized status (e.g., Cross, Helms, & Parham, 1998). Researchers have begun to conceptualize racial/ethnic identity as an important resilience resource in the normative development of African American youth (e.g., Cross et al., 1999; Spencer, Cunningham, & Swanson, 1995; Spencer et al., 1997). This view of ethnic identity, while recognizing the significant challenges that confront African American youth, also acknowledges the fact that many youth are resilient in the face of those challenges. An approach that views a strong, positive sense of ethnic identity as promoting achievement is consistent with a historical view of both Black and Hispanic immigrant communities that recognizes that because the groups were denied opportunities for education and advancement (during and after slavery for African Americans) or came to the United States because of the lack of opportunities in their countries of national origin (for many Hispanic and Asian American groups), they often placed a stronger emphasis on the importance of learning and education as the primary route to mobility (Chavous, et al., 2003).

Thus, ethnic identity can relate to a meaning-making process that affords members of historically oppressed ethnic minority groups an opportunity to define their racial membership in such a way that academic success can be seen as valuable despite structural- and individual-level barriers (such as stigma and racial discrimination) to academic success. For instance, findings from a study by Altschul, Oyserman, and Bybee (2006) indicate that African American middle school students who felt more connected to their Black identity and who linked their Black identity to a value for achievement were more academically motivated and performed better than youth who identified less with their ethnic group and who didn't view academic achievement as connected to their ethnic group identity. Chavous and colleagues (2003) also found that African American high school students who had a strong ethnic group identity accompanied by group pride and awareness of societal discrimination had more positive academic attitudes and showed higher academic persistence and postsecondary educational attainment than youth who de-emphasized their ethnic identities, felt less group pride, and who were less conscious of the potential for bias against their group.

Also, there is growing evidence that having a strong, positive sense of ethnic identity may protect minority adolescents from the negative psychological and academic

impacts of perceiving ethnic group barriers or experiencing interpersonal discrimination based on their ethnic group. For instance, in a 2006 study, Sellers and colleagues found that Black youth having an ethnic identity characterized by feelings of strong group connection and group pride showed more positive psychological well being when experiencing racial discrimination compared to those adolescents with less strong feelings of connection to and positive attitudes about their ethnic group. Wong and colleagues in their 2003 study found that African American adolescents who held a strong connection to and pride in being Blacks were protected from the negative impact on academic attitudes and performance of experiencing racial discrimination at school relative to those with less of a strong, positive connection with their ethnic group.

IMPLICATIONS FOR SCHOOLS AND EDUCATORS

Although ethnic identity may be influenced by and reflect the languages, customs, cultural values, and experiences deriving from youths' homes and communities, there is evidence that school settings can play important roles in youths' ethnic identity development. Researchers find that ethnic minority adolescents frequently report experiences related to race and ethnicity within their school settings (e.g., Fisher et al., 2000; Rosenbloom & Way, 2004; Wong et al., 2003). In particular, the secondary school context provides classroom and social structures that can result in heightened racial salience and more awareness of racial group differences, including stereotypes. For instance, entry into secondary schooling is associated with more ethnic cleavage in classes and peer social groups. Teachers and class curricula often emphasize social comparison more than in elementary grades, resulting in more attention to group differences in achievement and performance (Seidman, Allen, Aber, Mitchell, & Feinman, 1994).

At school, ethnic minority adolescents are likely to have White teachers from middle-class backgrounds, even in urban schools, and teachers in general are unlikely to have received extensive training in multicultural education (Ford & Harris, 1996). Additionally, ethnic minority youth report racially biased treatment within the classroom and peer contexts at school as common occurrences, e.g., perceiving that they received poor grades or evaluations from teachers and other adults at school or harsher discipline due to race, and social exclusion or harassment due to race (Fisher et al., 2000; Romero & Roberts, 1998). Thus, schools may contribute to youths' development of ethnic identities and the extent to which youth perceive their group identity as consistent with schooling and achievement.

Teacher training practices are not necessarily designed to equip teachers to work in multicultural class settings

(Delpit, 1995; Irvine, 1986; Ladson-Billings, 1995). This will continue to be a problem as the ethnic minority population continues to rise in the United States. As noted, a perspective prevalent among educators and in professional training of teachers is the "colorblind" ideology (Delpit, 1995; Markus, Steele, & Steele, 2000). However, ethnic identity research presents growing evidence that such a perspective does not relate to positive academic outcomes for ethnic minority youth and in fact may lead to increased cultural tensions and miscommunications. The research concerning the positive influences of a strong, positive ethnic identity on youth achievement outcomes suggest that the colorblind approach (or a de-emphasis on group membership and emphasis on conforming to mainstream values) may hinder teachers from seeing the needs of their ethnic minority students and may result in students not being acknowledged in ways that facilitate their achievement. Furthermore, while teachers may not be formally trained in theory and research related to race and education, many teachers enter their classrooms with some familiarity of the most prevalent perspectives on race in education. Unfortunately, they are most likely to be familiar with the notion that certain ethnic minority youth and their families devalue educational achievement and define their ethnic identity as inconsistent with achievement (or "acting White"), while the values of other youth and families include embracing education. Such misinformation may lead to making erroneous attributions and conclusions when students show lower performance and experience academic difficulty.

Thus, school practitioners must receive training about the development of youth from multicultural backgrounds. This training should not only acknowledge the unique risks associated with membership in ethnic minority groups in the United States but also consider how youths' ethnic identities can serve as cultural assets in relation to their achievement and how to use this information to create inclusive classroom contexts for all students. Without such training, it is likely that teaching approaches and practices will be based on popular views of common sense approaches not supported by empirical research. Additionally teachers should be mindful of endorsing their own ethnic identity beliefs in the class contexts they create.

EVALUATION (TEST) ANXIETY

In the era of the No Child Left Behind legislation there is a growing concern that high-stakes testing may have a negative impact on student learning and performance. Mulvenon, Stegman, and Ritter (2005) noted that a cursory review of the academic literature and national news sources on the impact of standardized testing reveals a plethora of anecdotal cases of students experiencing illness, anxiety, and heightened levels of stress. Furthermore, numerous studies have surveyed teachers regarding the impact of standardized tests, producing findings that low performance on these tests is correlated with increased levels of anxiety and stress. Mulvenon and colleagues conducted a survey and concluded that most of the dangers of standardized testing are overstated and that most students, parents, principals, and counselors do not report increased levels of stress or anxiety. Nevertheless, there remains a nationwide concern that an increase in high-stakes testing and test anxiety is harming students.

Test anxiety (TA) is a feeling of apprehension and discomfort accompanied by cognitive difficulties during a test. There is general consensus that it involves at least two components: (a) a pattern of physiological hyperarousal (i.e., increased heart rate, blood pressure, etc.) that may include physical changes and complaints, and (b) a cognitive obstruction or disorganization of effective problem-solving and cognitive control, including difficulty in thinking clearly (Friedman & Bendas-Jacobs, 1997). These two factors have also been termed *emotionality* (nervousness about the test situation) and *worry* (a cognitive aspect which involves concern over one's performance). A proposed third factor that has received less attention is social humiliation, referring to one's concern and awareness that others may negatively view the test performance. This third factor could easily be subsumed by the worry or cognitive component.

Test anxiety is similar to math anxiety in that both involve physiological and worry components. However,

Low performance on standardized tests has been correlated with increased levels of anxiety and stress. ©WILL & DENI MCINTYRE/CORBIS.

math anxiety can occur during math instruction and homework, whereas test anxiety only occurs in testing environments. Public speaking anxiety is also characterized by the cognitive and emotionality components, but much of the anxiety occurs before the event and tapers off after the first minute of the speech. TA is thought to persist throughout the testing experience, and its onset occurs at the start of the test.

TA has been studied as a construct for more than 50 years (Mandler & Sarason, 1952). Whether test anxiety causes poor test performance or whether previous poor test performance causes TA is unclear. Tobias (1985) proposed the latter causal relationship where previous low test scores are caused by inadequate study skills and/or poor test-taking skills, which in turn cause test anxiety. Research investigating the cause of TA has led to two models: the interference model and the skills deficit model (Birenbaum, 2007). The interference model states that high TA students are plagued by worry and distracting thoughts that interfere with their

ability to retrieve information during a test. The skill deficit model states that high TA students' problems occur before the test in the form of inadequate learning that results in poor performance. Thus, TA is simply an emotion that results from an awareness of being unprepared for the test. The former model stresses reducing TA whereas the latter model stresses an irrelevant role for TA and thus increasing learning strategies. Naveh-Benjamin and colleagues (1987) combined these models and distinguished between two types of TA students. One knows the material well but has trouble retrieving it, whereas the other has poor understanding of the material and thus cannot retrieve it. This entry refers to debilitating test anxiety, rather than facilitating test anxiety. The latter has been demonstrated in both early (Yerkes & Dodson, 1908) and subsequent (Alpert & Haber, 1960) studies where a small amount of anxiety actually improves test performance.

In this entry, normative data is provided on rates of anxiety levels, various correlates of TA are described, and evaluation and assessment of TA are discussed as are methods for helping students manage TA.

CORRELATES OF TEST ANXIETY

An excellent meta-analysis conducted by Hembree (1988) is the source of many of the conclusions presented here, and Hembree source gives a more complete coverage of TA. Where appropriate, these conclusions are updated with more recent research findings.

Normative data on rates of TA are difficult to estimate because as of 2008 large-scale studies have not been conducted. However, a study by Methia (2004) found that more than one-third of school age children experience at least some TA. As mentioned earlier, it is assumed that TA has increased in the early 2000s, possibly due to an increased emphasis on testing in schools. Whatever the precise prevalence rate may be, it is clear that TA remains a concern for educators.

Not surprisingly, TA has been found to be negatively correlated with tests of IQ and various types of achievement and aptitude (Hembree, 1988). Again, these data are correlational and not causal. Thus, it is as plausible that low achievement causes TA as it is to say that TA causes low achievement. In terms of motivational factors, although there is a negative correlation between need for achievement and TA in the elementary years, there appears to be no relationship during the high school and college years. There is a strong negative correlation between self-esteem and TA. Moreover, students with high TA tend to have an external locus of control (i.e., feeling as if they have little control over the events of their lives). TA is positively related with defensiveness

and both general state and trait anxiety, whereas it is negatively related with dominance.

One study tested the hypothesized negative impact of cognitive TA in the test preparation, performance, and reflection phases (Cassady, 2004). Students with high-cognitive TA reported lower study skills, rated tests as more threatening, and prepared less effective test notes. The high-anxiety students performed worse on tests and reported higher levels of emotionality. Cassady concluded that cognitive TA is associated with detrimental perceptions and behaviors in all phases of the learning-testing cycle.

Females typically are more prone to TA than are males, with the difference peaking during grades 5 through 10, and declining thereafter. However, this difference is not associated with lower test performance. In one study investigating differences between males and females, Chappell and colleagues (2005) found a small inverse relationship between TA and GPA in both groups. Low-test-anxious female graduate students had significantly higher GPAs than high-test-anxious female graduate students, but there were no GPA differences between low- and high-test-anxious male graduate students. Female undergraduates had significantly higher TA and higher GPAs than male undergraduates, and female graduate students had significantly higher TA and higher GPAs than male graduate students.

Both African American (in elementary school) and Hispanic students exhibit higher TA than do Caucasian students. Later-born children exhibit higher TA than do first-borns. Some researchers have proposed that TA among minority students may be partly explained by the stereotype threat hypothesis (Steele & Aronson, 1995). Based on the perception that there are negative stereotypes regarding certain groups' performance on standardized tests, group members experience higher anxiety on tests due to fear of being stereotyped or confirming the negative group stereotype. According to some, this hypothesis may help to explain why girls perform worse than boys on high-stakes math tests and why African American and Hispanic students perform worse on achievement tests than do Caucasian and Asian-American students (Osborne, 2007).

MEASURING TEST ANXIETY

Many scales are used for measuring test anxiety. Sarason's 1984 Reaction to Tests (RTT) questionnaire consists of four 10-item scales: two that measure the cognitive component (worry and test irrelevant thinking) and two that measure the emotional component (emotionality and bodily symptoms). The Friedban Scale (Friedman & Bendas-Jacob, 1997) of TA has 23 items covering three subdimensions: social derogation (eight items, e.g., "If I fail a test, I am afraid I shall be rated as stupid by my

friends.”), physical tenseness (six items, e.g., “I am very tense before a test, even if I am well prepared.”), and cognitive obstruction (nine items, e.g., “In a test, I feel like my head is empty, as if I have forgotten all I have learned.”). Internal consistency reliability coefficients for the three subscales in one study were .93, .88, and .94, respectively (Sawyer & Hollis-Sawyer, 2005), indicating satisfactory levels of internal consistency. The Test Anxiety Inventory for Children and Adolescents (Lowe & Lee, 2005) is a 45-item self-report measure for grades 4 through 12. Coefficient alphas for the TAICA have ranged from .81 to .94. There is also the Test Anxiety Inventory (Spielberger, 1980) used solely with adults. For a shorter scale that can be also be used with older students, the Westside Test Anxiety Scale (Driscoll, 2007) has 10 items covering self-assessed anxiety impairment and cognitions that can impair performance and is designed to identify students with anxiety impairments who may benefit from an anxiety-reduction intervention.

TREATING TEST ANXIETY

Most early treatments of TA were behavioral and mainly systematic desensitization—a process in which the person is trained in relaxation techniques in the presence of increasing levels of the aversive, anxiety-producing stimulus (here testing environments). Unfortunately, although the early treatments were successful in reducing TA, they were less successful in improving test performance (Allen, Elias, & Zlotlow, 1980). Tryon (1980) suggested that students also need study counseling combined with desensitization to improve test performance. However, Hembree (1988) concluded that TA reduction programs generally result in higher test performance and GPA. Ergene (2003) conducted a meta-analysis that synthesized results from TA reduction programs. The most effective treatments appear to be those that combine skill-focused approaches with behavior or cognitive approaches. Individually conducted programs, along with programs that combined individual and group counseling formats, have produced the greatest changes. More research is needed to clarify the causal role TA reduction programs may have with regard to achievement and test performance.

Regardless of its prevalence and severity, TA will continue to be a concern of parents and educators. In an era of heightened school accountability, schools (especially administrators and teachers) will be interested in ways to reduce TA in students so as to enhance test performance. Merely treating TA by desensitizing students to the testing situation may not improve their test performance because some students' struggles may be simply due to inadequate preparation. It is important to assess both TA and academic preparedness before deciding on an intervention program. Interventions that provide training in study skills

and test taking, combined with reducing the emotionality of the testing situation, are likely to be more successful in facilitating test performance.

Daniel H. Robinson

EXPECTANCY VALUE MOTIVATIONAL THEORY

Between 1980 and the early 2000s, Jacquelynne Eccles and colleagues studied the motivational and social factors influencing such long and short-range school-related goals and behaviors as school grades, course selections, and high school graduation. They elaborated a comprehensive theoretical model linking achievement-related choices to two sets of beliefs: the individual's expectations for success and the importance or value the individual attaches to the various options perceived by the individual as available (see Eccles, Wigfield, & Schiefele, 1998). In this model, they also specified the relation of these beliefs to cultural norms, experiences, aptitudes, and to those personal beliefs and attitudes that are commonly assumed to be associated with achievement-related activities (Eccles et al., 1998). In particular, they linked achievement-related beliefs, outcomes, and goals to interpretative systems such as causal attributions and other meaning-making beliefs linked to achievement-related activities and events, to the input of parents, peers, and teachers, to various social roles and other culturally based beliefs about both the nature of various tasks in a variety of achievement domains and the appropriateness of participation in such tasks, to self-perceptions and self-concepts, to perceptions of the task itself, and to the processes and consequences associated with identity formation.

For example, regarding engagement in school learning, they believe people will be most likely to engage fully in school-based learning activities if they have confidence in their ability to do well and place high value on doing well in school. High confidence in one's academic potential results from a history of doing well in school, as well from strong messages that one is academically competent from one's parents, teachers, and peers (Wigfield et al., 2006). Similarly, the personal value one attaches to learning in school is influenced by several factors: Does the person enjoy doing the subject material? Is the learning activity seen as instrumental in meeting one of the individual's long- or short-range goals? Is the person anxious about his or her ability to successfully master the learning material being presented? Does the person think that the learning task is appropriate for people like him or her?

Do the person's parents and teachers think doing well in school is important and have they provided advice on the utility value of school success for various future life options? Finally, does taking the working on the learning task interfere with other more valued options?

At the most basic psychological level, the Eccles and colleagues expectancy-value model reduces to two fundamental motivational questions: "Can I do the task?" and "Do I want to do the task?" If students answer no to the question "Can I do the task?" then they are unlikely to fully engage in the learning opportunities provided in school. But even if the answer to the first question is yes, full and sustained engagement in school learning depends on the answer to the question, "Do I want to do the task?" If the answer to this question is no, then it is also unlikely that the students will engage the learning opportunities at school.

ASKING "CAN I DO THE TASK?"

Research supports the hypothesis that a yes answer to the question, "Can I do the task?" predicts better performance and more motivation to select more challenging tasks (Wigfield et al., 2006). Importantly, confidence in one's ability to master academic work is a strong predictor of school achievement among academically struggling students (NRC, 2004). Unfortunately, negative racial, ethnic, gender, and social class stereotypes can lead teachers and school districts to communicate low expectations for the academic achievements of some groups of students through a variety of mechanisms, including differential teacher-student face-to-face daily interactions, tracking into low ability groups coupled with providing inferior educational experiences in these groups, failure to provide encouragement for high educational aspirations, and failure to provide high quality educational experiences that promote both current achievement levels and confidence and lay the groundwork for continued success in future courses (see Eccles, 2007).

ASKING "DO I WANT TO DO THE TASK?"

Fully engaging learning at school requires a desire to do the task (Wigfield et al. 2006). Eccles and colleagues argue that the perceived value of school work is determined by four related constructs: (1) the enjoyment one expects to experience while engaging in the task—intrinsic interest; (2) the extent to which engaging in the task is consistent with one's self-image or identity—attainment value; (3) the value of the task for facilitating one's long range goals or in helping one obtain immediate or long range external rewards—utility value; and (4) the perceived cost of engaging in the activity.

Intrinsic Value. Eccles and colleagues use the term *intrinsic value* to refer to either the enjoyment one feels when doing the task or the enjoyment one expects to experience while one is engaged in the task. This construct is most closely related to two related constructs: the idea of intrinsic motivation as developed by E. Deci and R. Ryan and the idea of interest as developed by theorists such as A. Krapp, A. Renniger, and U. Schiefele. According to Deci and Ryan, intrinsic motivation is highest when individuals are doing tasks that they enjoy, as well as when they are doing tasks that are personally meaningful (somewhat like *attainment value*). Interest theorists argue that engagement will be highest when individuals are doing interesting tasks. According to these theorists, interest value results from either inherent characteristics of the task (called *situational interest*) or personal characteristics of the individuals doing the task (called *personal interest*). Individual interest is considered a relatively stable evaluative orientation towards certain domains that one enjoys; situational interest is an emotional state aroused by specific features of an activity or a task. Evidence is quite strong that interests, intrinsic motivation, and intrinsic value predict greater academic engagement and learning (see Eccles et al., 1998; Wigfield et al., 2006).

Some educational psychologists are interested in individual differences in trait-like individual differences in what might be referred to as the desire to learn (e.g., Gottfried, Harter, Hidi, and Schiefele). These researchers define this enduring learning orientation in terms of three components: (1) preference for hard or challenging tasks, (2) learning that is driven by curiosity or interest, and (3) striving for competence and mastery. Empirical findings suggest that the three components are highly correlated and that high levels of a trait-like desire to learn is related to a mastery-oriented coping style for dealing with academic failure, high academic achievement, both comprehension and deep-level learning, and the use of appropriate self-regulated learning strategies in academic tasks (see Wigfield et al., 2006). Some scholars believe the component of interest should be considered as an influence on attainment value.

Situational learning is more transitory because it is based in the nature of the academic curriculum and materials themselves. The following task features arouse situational interest: personal relevance, both familiarity and novelty, high activity level, and comprehensibility (see Wigfield et al., 2006). These characteristics facilitate both engagement and learning. We classify this construct under intrinsic value.

Attainment and Utility Value. Eccles and colleagues use the term *attainment value* to refer to the link between tasks and individuals' own identities and preferences. As they grow up, individuals develop an image of who they

are and what they would like to be. This image is made up of many parts, including (1) conceptions of one's personality and capabilities, (2) long range goals and plans, (3) schema regarding the proper roles of men and women in one's culture group, (4) instrumental and terminal values, (5) motivational sets, (6) ideal images of what one should be like; (7) stable personal interests, and (8) social scripts regarding proper behavior in a variety of situations. Eccles and colleagues conceptualize attainment value in terms of these needs, personal interests, and personal values that an activity fulfills. Those parts of an individual's self-image that are central or critical to self-definition should influence the value the individual attaches to various activities such as school-based learning activities versus other activities. These differential values, in turn, should influence the individual's desire to engage fully in school-based learning activities. For example, if doing well in school and being a good student is a central part of an individual's self-image, then that person should place higher value on investing time and energy in doing well in school than in other pursuits because doing well in school has high attainment value for this individual.

Utility value is determined by how well a task fits into an individual's goals and plans or fulfills other basic psychological needs. For example, if students plan to become engineers then mastering arithmetic in elementary school and doing well in challenging mathematics and science courses in secondary school will have high utility value because it will allow them to take college track mathematics in secondary school and then get into college training programs in engineering. If not, then the value of doing the work necessary to succeed in these courses may be too low to motivate their effort.

Regarding what might influence the attainment value and utility of doing well and being engaged in school, J. Connell and colleagues proposed three basic human needs that should influence the attainment value of any task or situation: the needs for competence, relatedness, and autonomy. They argue that people's motivation to engage in the demands of any particular situation or setting is influenced by the extent to which the setting provides opportunities to experience autonomy, social relatedness, and a sense of competence. If schools and classrooms do not provide these opportunities, then individuals will not become engaged in school learning and will try to disengage by whatever means are available to them. In contrast, if classroom experiences provide opportunities for students to fulfill these basic needs, then the attainment value of fully engaging in the learning agenda of school should be increased.

The importance of competence needs, in particular, has received a great deal of attention in the achievement

literature. This research has shown that early school failure predicts disengagement from school (Eccles et al., 1998; Wigfield et al., 2006). Given this evidence, it is essential that teachers set up their instructional practices in ways that allow all children to experience success at their mastery attempts, particularly at critical school transitions when academic failure may precipitate a downward spiral of disengagement leading to school drop out. Researchers in the area of achievement goal theory (e.g., Maehr & Midgley) have explored the importance of mastery-oriented classrooms. These researchers hypothesize that school learning tasks vary along at least two important dimensions: (1) the extent to which mastery or improvement is stressed (i.e., a mastery focus); and (2) the extent to which doing better than others is stressed (i.e., a performance focus). They argue that the greater the focus on mastery instead of performance, the greater the likelihood that all students will feel competent and will have repeated experiences of mastery. Their research supports this hypothesis.

Evidence also supports the importance for school engagement. For example, several researchers (e.g., Goodenow, Patrich, Roeser, Ryan, & Wentzel), have shown that feelings of belongingness in classrooms and schools, as well as a sense of being part of a supportive learning community, predict increased engagement and school learning. In addition, one of the major benefits of both cooperative learning structures and Catholic schools is that they increase all students' sense of belonging in their classroom's and school's agenda (see Eccles, 2007).

In contrast, experiences of racial, ethnic, religious, linguistic, and gender discrimination are likely to undermine minority and female students' sense of belonging at school. For example, C. Wong and her colleagues showed that experiences of racial discrimination predicted declines in school achievement. Similarly, C. Steele and his colleagues argue that students who believe that their teachers have low expectations for their academic performance will disidentify with school learning as a way of coping with experiences of racial and ethnic discrimination at school (see Eccles, 2007).

Deci, Ryan, and their colleagues have done most of the work on the importance of support for autonomy in classrooms for students' motivation to fully engage the learning agenda of the classroom. They argue that individuals need to feel personally responsible for their behavior and their goals. To the extent that teachers create opportunities for this to be the case, students are more motivated to do their school work and learn the material better.

Eccles and colleagues believe that people need to feel that they are considered valuable contributors to their social groups and institutions. This need is likely to

become especially salient during adolescence. One intervention study was done based on this need: the Coca Cola study (see Eccles, 2007). In this project, at-risk adolescents were asked to provide cross-age peer tutoring in reading to first graders. Those adolescents who had this experience over an extended period of time showed an increased commitment to their own academic performance as evidenced by increases in their grades and high school graduation rates.

Individual differences in school motivation are also likely to be linked to individual differences in self-schema and both personal and social goals and identities. As noted above, these differences should be directly related to the perceived attainment value of various activities. The work of Eccles and colleagues on gender differences in high school math and science course enrollment illustrates the importance of the perceived utility value of various course options. Using longitudinal methods, they demonstrated that gender differences in students' decisions to enroll in advanced mathematics are mediated primarily by gender differences in the value that the students' attached to mathematics. More specifically, their findings indicate that young women are less likely than the young men to enroll in advanced high school mathematics and physics courses primarily because they feel that math and physical science are less important, less useful, and less enjoyable than do young men. Furthermore, young women tend to think that advanced math and physics are less important and enjoyable than the many other advanced high school courses they could be taking instead. Interestingly, interventions based on making physics more interesting to females by using more human biological examples of physical principles have been quite successful at increasing females' engagement in physics classes.

Perceived Cost. The value of a task also depends on a set of beliefs that can best be characterized as the cost of participating in the activity. Cost is influenced by many factors, such as anticipated anxiety, fear of failure, fear of the social consequences of success, such as rejection by peers or anticipated racial discrimination, or anger from one's parents or other key people, and fear of loss of a sense of self-worth.

This conceptualization of cost is similar to the kinds of dynamics discussed by M. Covington in his self-worth theory. Covington defined the motive for self-worth as the desire to establish and maintain a positive self-image or sense of self-worth. Because children spend so much time in classrooms and are evaluated so frequently there, Covington argued that protecting one's sense of academic competence is likely to be critical for maintaining a positive sense of self-worth. However, school evaluation, competition, and social comparison can make it difficult

for some children to maintain the belief that they are competent academically. Covington outlined various strategies children develop to avoid appearing to lack ability, including procrastination, making excuses, avoiding challenging tasks, and not trying. Therefore, if failure seems likely, some children will not try, precisely because trying and failing threatens their ability self-concepts.

Avoiding challenging tasks is a good way to avoid or minimize failure experiences. Similarly, work by R. Newman and his colleagues demonstrated that students may be reluctant to ask for help in classrooms because they think that this will make them appear to be stupid.

Cost can also be conceptualized in terms of the loss of time and energy for other activities. People have limited time and energy. They cannot do everything they would like. They must choose among activities. Eccles and colleagues asserted that cost is especially important to choice and that socio-cultural processes linked to social identity formation and cultural socialization should have a big influence of the perceived cost of the various activities competing for young people's time and energy. Schools need to provide young people with genuine reasons for attaching higher subjective task value to engaging in school work than in engaging in the variety of tasks associated with other aspects on their daily lives.

As noted above, the expectancy-value model focuses attention on two fundamental motivational questions: "Can I do the task?" and "Do I want to do the task?" The first question illustrates the expectancy component. If students answer no to this question, then they will be unlikely to fully engage in the learning opportunities provided in school. But even if the answer to this question is yes, full and sustained engagement in school learning depends on the answer to the question "Do I want to do the task?" This question illustrates the value component of the model. If the answer to this question is no, then it is also unlikely that the students will engage the learning opportunities at school. It is critical that school environments provide students with the kinds of experiences that will allow them to answer yes to both of these questions.

EXPERIMENTAL RESEARCH

Suppose teachers wished to determine which of two methods of reading instruction was most effective—one that involved 20 minutes of direct instruction in phonics each day throughout the academic year in grade 1 or one that involved the current practice of having the teacher read a book to the class for 20 minutes each day throughout the year in grade 1. Similarly, suppose they wished to determine whether children learn better in a small class (i.e., with 15 students) or a large class (i.e., with 30 students). Finally, suppose they wished to determine whether requiring students to take a short quiz during each meeting of a college lecture class would result in better performance on the final exam than not giving quizzes.

Each of these situations can be examined best by using experimental research methodology in which investigators compare the mean performance of two or more groups on an appropriate test. In experimental research, it is customary to distinguish between the independent variable and the dependent measure. The independent variable is the feature that is different between the groups—for example, whether 20 minutes of time each day is used for phonics instruction or reading aloud to students, whether the class size is small or large, or whether a short quiz is given during each class meeting. The dependent measure is the score that is used to compare the performance of the groups—for example, the score on a reading test administered at the end of the year, the change in performance on academic tests from the beginning of the year to the end of the year, or the score on a final exam in the class. When researchers compare two or more groups on one or more measures, they use experimental research methodology.

EXPERIMENTAL RESEARCH DEFINED

Experimental research is based on a methodology that meets three criteria: (a) random assignment—the subjects (or other entities) are randomly assigned to treatment groups, (b) experimental control—all features of the treatments are identical except for the independent variable (i.e., the feature being tested), and (c) appropriate measures—the dependent measures are appropriate for testing the research hypothesis. For example, in the class

size example, random assignment involves finding a group of students and randomly choosing some to be in small classes (i.e., consisting of 15 students) and some to be in large classes (i.e., consisting of 30 students). The researcher cannot use pre-existing small or large classes because doing so would violate the criterion of random assignment. The problem with violating random assignment is that the groups may systemically differ; for example, students in the smaller classes may be at more wealthy schools that also have more resources, better teachers, and better-prepared students. This violation of the random assignment criterion, sometimes called *self-selection*, is a serious methodological flaw in experimental research.

In the class size example, the criterion of experimental control is reflected in having the classes equivalent on all relevant features except class size. That is, large and small classes should have teachers who are equivalent in teaching skill, students who are equivalent in academic ability, and classrooms that are physically equivalent; they should also have equivalence in support services, length of school day, percentages based on gender, English language proficiency, ethnicity, and so on. If the groups differ on an important variable other than class size, determining whether differences in test performance can be attributed to class size will be difficult. This violation of the experimental control criterion, called *confounding*, is a serious methodological flaw in experimental research.

Finally, in the class size example, the dependent measure should test the research hypothesis that class size affects academic learning, so an appropriate measure would be to give an achievement test covering the curriculum at the start and end of the year. The appropriate measures criterion would be violated if the dependent measure were a survey asking students how well they enjoyed school this year or an ungraded portfolio of their artwork over the year. When a test does not measure what is intended, the test lacks *validity*; invalid tests represent a serious methodological flaw in experimental research.

BENEFITS AND LIMITATIONS OF EXPERIMENTAL RESEARCH

Experimental research is generally recognized as the most appropriate method for drawing causal conclusions about instructional interventions, for example, which instructional method is most effective for which type of student under which conditions. In a careful analysis of educational research methods, Richard Shavelson and Lisa Towne concluded that “from a scientific perspective, randomized trials (we also use the term experiment to refer to causal studies that feature random assignment) are the ideal for establishing whether one or more factors caused change in an outcome because of their strong ability to enable fair comparisons” (2002, p. 110). Sim-

ilarly, Richard Mayer notes: “experimental methods which involve random assignment to treatments and control of extraneous variables have been the gold standard for educational psychology since the field evolved in the early 1900s” (2005, p. 74). Mayer states, “when properly implemented, they allow for drawing causal conclusions, such as the conclusion that a particular instructional method causes better learning outcomes” (p. 75). Overall, if one wants to determine whether a particular instructional intervention causes an improvement in student learning, then one should use experimental research methodology.

Although experiments are widely recognized as the method of choice for determining the effects of an instructional intervention, they are subject to limitations involving method and theory. First, concerning method, the requirements for random assignment, experiment control, and appropriate measures can impose artificiality on the situation. Perfectly controlled conditions are generally not possible in authentic educational environments such as schools. Thus, there may be a tradeoff between experimental rigor and practical authenticity, in which highly controlled experiments may be too far removed from real classroom contexts. Experimental researchers should be sensitive to this limitation, by incorporating mitigating features in their experiments that maintain ecological validity.

Second, concerning theory, experimental research may be able to tell that one method of instruction is better than conventional practice, but may not be able to specify why; it may not be able to pinpoint the mechanisms that create the improvement. In these cases, it is useful to derive clear predictions from competing theories so experimental research can be used to test the specific predictions of competing theories. In addition, more focused research methods such as naturalistic observation or in-depth interviews may provide richer data that allows for the development of a detailed explanation for why an intervention might have a new effect. Experimental researchers should be sensitive to this limitation, by using complementary methods in addition to experiments that provide new kinds of evidence.

EXPERIMENTAL DESIGNS

Three common research designs used in experimental research are between subjects, within subjects, and factorial designs. In between-subjects designs, subjects are assigned to one of two (or more) groups with each group constituting a specific treatment. For example, in a between-subjects design, students may be assigned to spend two school years in a small class or a large class. In within-subjects designs, the same subject receives two (or more) treatments. For example, students may be assigned to a small class for one year and a large class

RANDOMIZED TRIALS IN EDUCATIONAL RESEARCH

Experimental research helps test and possibly provide evidence on which to base a causal relationship between factors. In the late 1940s, Ronald A. Fisher (1890–1962) of England began testing hypotheses on crops by dividing them into groups that were similar in composition and treatment to isolate certain effects on the crops. Soon he and others began refining the same principles for use in human research.

To ensure that groups are similar when testing variables, researchers began using randomization. By randomly placing subjects into groups that say, receive a treatment or receive a placebo, researchers help ensure that participants with the same features do not cluster into one group. The larger the study groups, the more likely randomization will produce groups approximately equal on relevant characteristics. Nonrandomized trials and smaller participant groups produce greater chance for bias in group formation. In education research, these experiments also involve randomly assigning participants to an experimental group and at least one control group.

The Elementary and Secondary Education Act (ESEA) of 2001 and the Educational Sciences Reform Act (ERSA) of 2002 both established clear policies from the federal government concerning a preference for “scientifically based research.” A federal emphasis on the use of randomized trials in educational research is reflected in the fact that 70% of the studies funded by the Institute of Education Sciences in 2001 were to employ randomized designs.

The federal government and other sources say that the field of education lags behind other fields in use of randomized trials to determine effectiveness of methods. Critics of experimental research say that the time involved in designing, conducting, and publishing the trials makes them less effective than qualitative research. Frederick Erickson and Kris Gutierrez of the University of

California, Los Angeles argued that comparing educational research to the medical failed to consider social facts, as well as possible side effects.

Evidence based research aims to bring scientific authority to all specialties of behavioral and clinical medicine. However, the effectiveness of clinical trials can be marred by bias from financial interests and other biases, as evidenced in recent medical trials. In a 2002 Hastings Center Report, physicians Jason Klein and Albert Fleischman of the Albert Einstein College of Medicine argued that financial incentives to physicians should be limited. In 2007 many drug companies and physicians were under scrutiny for financial incentives and full disclosure of clinical trial results.

Teresa Odle

for the next year, or vice versa. Within-subjects designs are problematic when experience with one treatment may spill over and affect the subject's experience in the following treatment, as would likely be the case with the class size example. In factorial designs, groups are based on two (or more) factors, such as one factor being large

or small class size and another factor being whether the subject is a boy or girl, which yields four cells (corresponding to four groups). In a factorial design it is possible to test for main effects, such as whether class size affects learning, and interactions, such as whether class size has equivalent effects for boys and girls.

Finally, a quasi-experiment has the trappings (and some of the advantages) of an experiment but may not fully meet all of the criteria, such as a study in which matched groups are used (rather than randomly assigned groups) or a study that compares people based on a characteristic (such as differences between boys and girls or high and low-achieving students).

COMPARISON TO OTHER RESEARCH METHODS

In educational research, it is customary to distinguish between experimental and observational research methods, quantitative and qualitative measures, and applied versus basic research goals.

First, if experimental methods are preferred for testing causal hypotheses, what is the role of observational methods, in which a researcher carefully describes what happens in a natural environment? Observational methods can be used in an initial phase of research, as a way of generating more specific hypotheses to be tested in experiments, and observational methods can be used in conjunction with experiments to help provide a richer theoretical explanation for the observed effects. However, a collection of observations, such as portions of transcripts of conversations among students, is generally not sufficient for testing causal hypotheses. An important type of observational method is a correlational study, in which subjects generate scores on a variety of measures. By looking at the pattern of correlations, using a variety of statistical techniques, it is possible to see which factors tend to go together. However, controlled experiments are required in order to determine if the correlated factors are causally related.

Second, should educational research be based on quantitative measures (e.g., those involving numbers) or qualitative measures (e.g., those involving verbal descriptions)? Experiments may use either type of measure, depending on the research hypothesis being tested, but even qualitative descriptions can often be converted into quantitative measures by counting various events.

Third, should educational research be basic or applied? In a compelling answer to this question, Donald Stokes argues for “use-inspired basic research” (1997, p. 73). For example, in educational research, experimental researchers could examine basic principles of how instruction influences learning, that is, experiments aimed at the basic question of how to help people learn within the practical setting of schools.

HISTORICAL OVERVIEW AND 21ST CENTURY TRENDS

Applying experimental research methods to questions about human behavior is recognized as one of the greatest scientific advances of the 20th century. Between 1975 and 2005, in particular, experimental research methodology has enabled an explosion of educationally relevant

findings on how to design effective instruction in subject areas such as reading, writing, mathematics, and science.

In spite of these advances, Peggy Hsieh and colleagues (2005) found that the percentage of articles based on randomized experiments declined from 40 percent in 1983 to 26 percent in 2004 in primary educational psychology journals and from 33 percent in 1983 to 4 percent in 2004 in primary educational research journals. The authors conclude that “the use of experimental methodology in educational research appears to be on the decline” (Hsieh et al., 2005, p. 528). They characterize the decline as “unfortunate” especially in light of growing concerns about “the untrustworthiness of educational research findings” (Hsieh, et al., 2005, p. 528). In a slightly earlier report to the National Research Council, Shavelson and Towne also noted the consensus view that the “reputation of educational research is quite poor” (2002, p. 23). The decline in training in experimental research methods in schools of education can be seen as an example of the deskilling of educational researchers, marginalizing one of the most powerful and productive research methodologies and ultimately marginalizing educational researchers as well.

Valerie Reyna notes that, as a reaction against the perceived low quality of educational research, members of the U.S. Congress passed bills that were signed into law in 2001 and 2002 requiring that educational practices in the United States be based on “scientifically-based research” (2005, p. 30) Reyna shows that the definition of scientifically based research includes research using “experimental or quasi-experimental designs in which individuals . . . are assigned to different conditions and with appropriate controls to evaluate the effects of the condition of interest” and using “measures . . . that provide reliable and valid data” (2005, p. 38). According to Reyna “two landmark pieces of legislation were passed that could substantially change educational practice” not by endorsing a particular program or policy but rather by calling for educational researchers to “embrace . . . the scientific method for generating knowledge that will govern educational practice in classrooms” (2005, p. 49). Similarly, in their report to the National Research Council, Shavelson and Towne call for “evidence-based research” in education—the fundamental principle of science that hypotheses should be tested against relevant empirical evidence rather than ideology, opinion, or random observation (2002, p. 3).

Early 21st-century trends in experimental research include the use of effect size, meta-analysis, randomized field trials, and net impact.

The Use of Effect Size. Effect size is a measure of the strength of an effect in an experiment. Jacob Cohen (1988) suggested a simple measure of effect size—referred to as Cohen’s *d*—in which the mean of the control group is subtracted from the mean of the treatment group and this

difference is divided by the pooled standard deviation of the groups. According to Cohen, effect sizes can be classified as small ($d = .2$), medium ($d = .5$) and large ($d = .8$). Use of effect size allows educational policy makers to determine if an instructional treatment causes a statistically significant effect and if it has a practical effect. Hsieh et al. reported an increase in studies reporting effect size in educational psychology journals between 1995 and 2005, starting with 4 percent in 1995 to 61 percent in 2004, whereas the rate remained steady at about 25 percent from 1995 to 2004 for a primary educational research journal (2005).

The Use of Meta-analysis. The effect size measure allows for a particular instructional effect to be compared across experiments using a common metric, yielding a new kind of literature synthesis called meta-analysis. In meta-analysis, researchers tally the effect sizes of the same comparison across many different experiments, yielding an average effect size. For example, Gene Glass and Mary Smith (1978) reported a pioneering meta-analysis of research on class size revealing small positive effects of smaller class size. In the early 2000s meta-analysis is commonly used to review and summarize experimental research.

The Use of Randomized Trials. Randomized field trials (RFT), randomized clinical trials (RCT) and randomized trials (RT) refer to a particularly rigorous form of experimental research in which students (or other entities) are randomly assigned to treatments within an authentic field setting. Gary Burtless states that “a randomized field trial . . . is simply a controlled experiment that takes place outside a laboratory setting” (2002, p. 180).

Although randomized trials have been used in medical research and research on public policy, they are rarely used in educational research. However, there are some notable exceptions such as a study of effects of class size conducted in Tennessee, reported by Jeremy Finn and Charles Achilles (1999). As part of the study, 11,600 students in 79 schools across the state were assigned along with their teachers to small classes (13–17 students), regular classes (22–26 students), or regular classes with full-time teacher aides. Students stayed in the program from kindergarten through third grade, and then all were returned to regular classes. Importantly, the study showed that students in the small classes outperformed those in the regular classes, with or without aides, and the effects were greatest for minorities. Frederick Mosteller called the Tennessee class size study “one of the most important educational investigations ever carried out” (1995, p. 113). In the foreword to *Evidence Matters* by Frederick Mosteller and Robert Boruch, the authors observe, “When properly conducted, randomized field trials—often called the gold standard in research involving human subjects—allow for fairly precise estimates of

programmatic effects” (2002, p. vi). Using an appropriate unit of measure (for example, individual students, classrooms, or schools) is an important consideration in research using randomized field trials.

Net Impact. Judith Gueron (2002, p. 18) distinguishes between an intervention’s outcomes (e.g., the percentage of students graduating from a school or passing a certification test) and its net impact (e.g., the percentage who graduate or who pass a certification test who would not have without the intervention). Gueron argues that “administrators often know and tout their program’s outcomes, but they rarely know the program’s net impacts” (p. 18). When administrators focus on the question, “Is the new intervention effective?” they focus only on outcomes. When they focus on the question, “Does the new intervention have more impact than the current practice?” they focus on net impact. In order to determine an intervention’s net impact, experimental researchers compare the outcomes with current practice (e.g., current instructional method) to the outcomes with the new intervention (e.g., the new instructional method). In short, Gueron argues that the question “Compared to what?” is an important and profound issue in experimental research.

In their analysis of educational research methodologies, Shavelson and Towne note: “decisions about education are sometimes instituted with no scientific basis at all, but rather are derived from ideology or deeply held beliefs” (2002, p. 17). In contrast, experimental research methodology has the potential to be a tool for promoting effective change in education in which decisions about instructional interventions are guided by scientific evidence and grounded in research-based theory. In the preface to Gary Phye, Daniel Robinson, and Joel Levin’s *Empirical Methods for Evaluating Educational Interventions*, Gary Phye observed: “we are on the cusp of a reaffirmation that experimental research strategies provide the strongest evidence” for testing the effects of educational interventions (2005, p. xi). Finally, Robert Boruch quotes Walter Lippman who, in the 1930s, said: “Unless we are honestly experimental, we will leave the great questions of society and its improvement to the ignorant opponents of change on the one hand, and the ignorant advocates of change on the other” (2005, p. 189). In short, the experimental research methodology that fueled an explosion of scientific research about humans in the 1900s remains a powerful and indispensable tool for educational researchers in the new millennium.

EXPERT-NOVICE STUDIES

Expert-novice studies involve natural contrasts between individuals at *relatively* high performance levels in a given domain (academic discipline or profession or hobby) and individuals at a *relatively* low performance level in that given domain. The word “relatively” is emphasized because expertise is a continuum rather than two discrete states and a given study usually just compares two points

along the continuum. For example, one classic study compared physics faculty (experts) against physics graduate students (novices), whereas another classic study compared undergraduates who had performed very well in an introductory course (experts) against undergraduates who performed much less well in that same course (novices).

Some researchers use the terms *expert* and *novice* in a more restricted, absolute way. For example, expert, for these researchers, is applied to individuals having spent at least 10 years of focused practice in a domain. This categorization method is called the 10-year-rule. It is based on the empirical observation that world-class expertise in a domain generally takes at least 10 years of focused practice, whether that domain be game playing, sports, writing, music composition, music playing, or scientific research (Hayes, 1985). The term novice, in the absolute sense, applies to individuals who have just learned the basics of the given domain but have not had an opportunity to practice. In other words, they can do basic tasks in the domain (unlike completely uninformed individuals), but only at a very low level of performance.

In general, experts are much faster and more accurate than novices in typical tasks in the domain of expertise being examined. Expert-novice studies have examined many different possible factors underlying this large performance difference, including differences in memory ability (how much of a problem is remembered), facts/chunks (how many example situations are known), representations/schemas (what features of problems are perceived), and procedures/strategies (what solution methods are used). Expert-novice differences have been found for all of those factors, although particular expert-novice studies tend to focus on only a subset of these dimensions, as illustrated in the following prototypical studies.

PROTOTYPICAL STUDIES

Chase and Simon (1973) recruited three participants of varying chess skill for their study (one master chess player, one Class A player, and one beginner). Each participant completed two different tasks involving side-by-side chessboards with a divider between them. The left board presented a different configuration each trial, and the right board was used by the participants to make responses. For the perception task, the participants were asked to recreate 14 game configurations, completing each as quickly and accurately as possible. For the memory task, the participants viewed an additional 14 game configurations for only five seconds and needed to recreate each configuration from memory. Each configuration was repeated until the participant correctly recreated the configuration. The game configurations varied by whether they were selected from the middle of a game or the end of the game and whether they were actual game configurations or random organizations of the pieces (i.e., unlikely to occur in a game).

Chase and Simon found that recall ability increased with chess skill ability. This relationship only occurred in recreations of actual configurations, not with random configurations. Chase and Simon hypothesized that the expert memory advantage was specific to actual configurations because experts saw chessboards in terms of familiar chunks, and random configurations did not have familiar chunks. Chase and Simon empirically estimated chunk size by using the time intervals between the placements of each chess piece as participants were recreating the configurations. Using this information to parse the chunks for each participant, they found that master chess players indeed had more chunks and larger chunks than the less skilled players. Even though the chunk size was larger, the chunks still fit within the accepted memory span that is to say, chess masters did not have better memory ability, just bigger chunks.

Another classic expert-novice study involved the study of representations rather than chunks. Chi, Feltovich, and Glaser (1981) recruited 16 participants of varying physics knowledge (eight experts included advanced PhD students from the physics department and eight novices included undergraduates who had just completed a semester of mechanics). Each participant sorted 24 physics problems selected from eight chapters of a physics textbook that were copied onto note cards. They were instructed to make their categorizations based on the similarities of the solutions. After the sorting process, they explained why they chose to group certain problems.

While there were no differences in the number of categories the experts and novices used in the sorting task, there was very little overlap in the category labels used by the experts and novices. From both the categorizations and the explanations, it was clear that novices grouped by what the problems looked like (e.g., incline planes or pulley problems) and experts grouped by the major physics principle necessary to solve each problem (e.g., conservation of energy problems or Newton's second law).

ROLE OF EXPERT NOVICE STUDIES IN EDUCATIONAL RESEARCH

Expert-novice studies have many important roles in educational research. First, they define the educational end point. The core of educational research is about defining how to structure teaching and learning rather than in defining what should be taught or learned, at least with respect to the end point of learning. From somewhere else, there must be input on the appropriate targets of learning. Expert-novice studies are a very important method of specifying those targets, and they are a method that has systematic advantages over simply asking disciplinary experts to list the target knowledge. The reason is that one hallmark of expertise is that much of the knowl-

edge is tacit and situationally evoked (Patel, Arocha, & Kaufman, 1999) experts don't know all the things they know and do, and it is hard to systematically extract the things they do know.

Second, expert-novice studies define the educational start point. Young children are remarkably adept at some things (e.g., extracting patterns from statistics in the environmental input) and young adults are remarkably weak at other things (e.g., reasoning about confounded variables in very simple situations). Research on where novices sit with respect to experts establishes empirically where the biggest gains need to be made by the learner.

This start-to-endpoint view of expert-novice studies connects with a knowledge decomposition view of curriculum design: what are all the individual knowledge and skill components that make up the goals of educational interventions (Gagne, 1962)? Here the assumption is that expertise is made up of many independent skills and knowledge, and instruction must cover each of these skills and knowledge in some logical order.

A variation of this decomposition perspective, derived from expertise research that emphasized the contextualized nature of knowledge and skills, is that experts not only know facts and have separable skills but are also better able to selectively and appropriately apply facts and skills in particular contexts (Lemaire & Siegler, 1995). For example, the early expertise studies on chess suggested that experts had tens of thousands of chess chunks, but the research also showed that experts had associated moves with these chunks that allowed them to quickly "see" which moves were worth considering. The educational implication is that students must learn these connections with the correct contexts (and perhaps break connections with the wrong contexts).

A third important use of expert-novice studies for educational research is to provide models of some form of education that was clearly successful. Expertise research has generally ruled out the genetic or talent perspective on expertise, which makes especially salient the question of what environmental factors were in place to develop that expertise (Ericsson, Krampe, & Tesch-Roemer, 1993). That is, can we develop better models for instruction on the basis of these success stories? For example, some researchers have considered the ways in which experts and novices interact in many settings that lead to high levels of expertise (e.g., in a professional or sport setting), namely apprenticeship. The observation is that novices are asked to participate in authentic disciplinary activities from the beginning (e.g., playing in full basketball games), and move gradually from peripheral, supporting roles to central, independent roles (Collins, Brown, & Newman, 1989). Another important educational implication from this angle on expertise research is the central importance of

focused practice: expertise is developed through thousands of hours of focused, regular practice, and curricula that devote much less time to an important topic are unlikely to be successful (Ericsson et al., 1993).

A fourth focus involves the importance of some expertise for learning in addition to performance. For example, research on learning by analogy has found that more expert students are better able to find relevant features in examples and learn by analogy to these examples than more novice students, who tend to encode problems in more superficial ways (Novick, 1988). This kind of research suggests which knowledge and skills should be placed earlier in the curriculum because they enable or accelerate later learning.

EXPERT EXPERT EXTENSIONS OF EXPERT NOVICE RESEARCH

Expertise is often treated as a single dimension, such that there is only one way of being more expert in a given domain. However, expertise is actually more nuanced than that single dimension view, and individuals can be more or less expert on different dimensions. For example, a person might be an expert on facts of a domain, but not expert in the skills of a domain, such as in the case of a U.S. Civil War buff with no training in historical thinking. Another person might have considerable training in the skills relevant to a particular domain but relatively little knowledge of the facts relevant to that domain, such as in the case of a physics researcher working on biology research. Studies that compare different kinds of experts allow for some teasing apart of the importance of different kinds of knowledge or skill on performance in different kinds of circumstances. For example, Voss, Tyler, and Yengo (1983) compared political scientists with expertise in the Soviet Union against political scientists with expertise on other regions, as well as comparing them to chemistry faculty and undergraduates. They found that some aspects of reasoning performance (on a problem relating to solving a political science problem involving the Soviet Union) depended upon training in political science in general whereas other aspects of reasoning performance depended specifically on being an expert on that exact region.

Most importantly for educational research, expert-expert studies can address the central educational question of generality and transfer of knowledge. A tension in curriculum design is the extent to which reasoning skills can be taught outside of a context or in some arbitrary context, or whether reasoning skills must be taught specifically in the context in which they will be later used. An example would be statistics or research methods. These are often stand-alone courses, with the idea that students will later be able to apply the skills learned in those courses to

whatever later contexts they need to apply them in, even if those contexts involve reasoning *about* very different content. The alternative approach is to teach only more specialized reasoning courses that are specific to subgroups of students' goal reasoning domain, or maybe have them take many such courses if they are unsure about their target domain. The general reasoning course approach is more efficient, but depends upon there being successful transfer. Expert-expert studies help address this question methodologically: if an expert in one domain can successfully solve problems in another domain, then the general training approach is a viable one. In fact, some recent studies have found generality to many aspects of training (e.g., Schunn & Anderson, 1999).

STATISTICAL ANALYTICAL TECHNIQUES USED IN EXPERT NOVICE RESEARCH

Although expertise is really a continuum rather than true categorical stages as the term "expert-novice" implies, expert-novice studies tend to focus on extreme group comparisons. Thus, the independent variables tend to be categorical. Dependent variables used in expert-novice research can be quite diverse, ranging from simple quantitative performance measures (such as accuracy or solution time) to more qualitative measures such as protocol analysis. In the case of simple performance metrics, basic univariate statistics such as ANOVA and t-tests are commonly used. In the case of protocol analysis, statistical techniques relevant to analysis of frequencies are used (e.g., Chi-Squared or other non-parametric tests). Because experts are often hard to find in large quantities, the minimum N assumptions of many statistical tests are not met, and low N variations of those tests are required (e.g., Fisher-exact instead of Chi-Squared).

STRENGTHS AND WEAKNESSES OF EXPERT NOVICE RESEARCH

In abstract terms, expert-novice research generally involves high external validity at the cost of low internal validity. To be more specific, expert-novice contrasts tend to involve participants similar to ultimate situations of interest working on tasks of ultimate interest, in contrast to using participants of convenience working on highly simplified tasks with questionable levels of motivation to perform the given experimental tasks. However, the downside is that the statistical power of the studies is often low because experts are hard to find and the statistical method is by necessity the lower powered, between-subjects method. There are also many confounded variables bundled with expertise because one cannot randomly assign participants to expertise. Thus,

expert-novice research is an excellent methodological tool that should work in conjunction with other techniques that have better statistical power and methodological control but perhaps lower external validity.

Another important methodological feature of expert-novice research involves confirmatory versus exploratory research. Because expertise is a natural variable rather than an experimentally controlled one, expertise research tends to be more exploratory. Exploratory research has the advantage of being able to provide many unexpected findings, but it often involves looking at many possible dependent variables to find which of the many complex ways in which expertise could express itself is relevant to the given domain/task being studied. This “fishing expedition” nature of data analysis in expert-novice studies is why qualitative data is so often collected—it allows the researcher to explore many different dimensions of behavior after the data is collected. It also explains why expert-novice studies are slow to be analyzed and published.

EXPERTISE

The notion of expertise underlies many facets of the educational process. Educators look to subject matter experts to inform the selection of content and establish levels of optimal performance against which student performance can be compared. Expert teachers are highly valued and actively sought out to serve as mentors and master teachers for those who are less experienced in the classroom. It is also hoped that students acquire expertise in some area so that they may be successful in their future academic and professional endeavors. Despite the centrality of expertise in education, however, there are substantial challenges that exist in defining it.

DEFINITIONS OF EXPERTISE

Expertise is difficult to define with precision. Generally, experts are expected to outperform non-experts consistently on tasks in a specific domain. However, scholars disagree about the most effective means by which to identify these individuals. K. Anders Ericsson (1948) argues that experts are those individuals who reliably excel on specific key tasks that are central to performance in a domain (Ericsson & Smith, 1991). In contrast, Robert Sternberg (1949) suggests that such narrowly bounded criteria are inauthentic and do not represent expertise as it occurs in professional settings (Sternberg & Horvath, 1995, 1998; Sternberg, Gigorenko, & Ferrari, 2002). Rather than relying on a static list of necessary and sufficient characteristics for expertise, he advocates a “family resemblance” approach in which the central tendencies of expertise (proficiency, experience, etc.) may manifest differently among different experts within and across domains.

It is also an open question in some domains whether or not it is possible to be an expert. James Shanteau (1943) reports that the reliability of expert evaluations and predictions varies significantly by domain. For example, expert weather forecasters are almost perfectly consistent ($r=0.98$) in their predictions when presented with the same information on different occasions (Shanteau, 2000; Shanteau, Weiss, Thomas, & Pounds, 2002). In contrast, expert stockbrokers ($r=0.40$) and expert pathologists ($r=0.50$) are fairly inconsistent. Similarly, the level of agreement between experts in a field varies between

domains and is closely related to rates of internal consistency. Shanteau suggests that evidence of unreliability in expert judgment does not inherently invalidate claims of expertise. In some cases, experts may discern multiple valid paths to reach a desired goal and evaluate the information at hand in that context. In other cases, the scientific knowledge base that supports experts' decision-making may itself be underdeveloped—as is the case in social sciences such as economics, psychology, and education. Experts in these domains may apply the best available knowledge of the field consistently and effectively but need to fill knowledge gaps with personal judgments that are less reliable.

In contrast, Robyn Dawes (1936) argues that expertise can exist only in fields for which advanced training and accumulated experience lead to higher reliability and success rates. His 1994 book, *House of Cards*, analyzed the fields of clinical psychology and psychotherapy and found that licensed practitioners were no more successful in helping their clients than laypeople with minimal training. Further, supposed experts in the field were no more accurate than novices when interpreting the results of psychological tests (e.g., Rorschach and sentence completion tests) or predicting the future behaviors of the individuals whom they evaluated. His conclusion was that expertise could not exist in the domain.

The problem of defining expertise increases for fields in which there is little agreement on desired outcomes or best practices. In the field of education, for example, identifying and expert teachers and training novices to become experts are considered to be crucial. The early work of David Berliner (1938) and others observed that teachers considered to be experts typically had a superior understanding of relevant factors impacting classroom dynamics, were better able to improvise during lessons to adapt to their students' abilities, and more successfully managed competing demands for their limited attentional resources (Berliner, 1986, 1987; Carter, Sabers, Cushing, Pinnegar, & Berliner, 1987; Carter, Cushing, Sabers, Stein, & Berliner, 1988; Sabers, Cushing, & Berliner, 1991).

However, in his recent work, Berliner (2005) suggests that two major issues prevent an adequate understanding of expertise in teaching. First, there are multiple standards of "good teaching" that are dependent upon cultural norms. Second, there is persistent disagreement on the desired outcomes of public education and appropriate ways to measure student success in relation to them. Thus, an expert teacher would need to be both a "good" teacher in a cultural sense by implementing commonly embraced practices and an "effective" teacher in terms of measured student learning outcomes (Berliner, 1987, 2005). The fact that teaching effectiveness must be evaluated on the basis of students' achievement

rather than the actions of the teachers themselves further problematizes the concept of the expert pedagogue, because cultural, contextual, and personal factors impact student performance and are beyond the control and/or professional responsibility of an individual teacher.

RESEARCH FINDINGS ON EXPERTISE

Research stemming from the field of cognitive psychology in the 1970s and 1980s has yielded a sizeable body of evidence for common traits across domains of expertise. The seminal book by Michelene Chi, Robert Glaser, and Marshall Farr, *The Nature of Expertise* (1988), compiled examinations of data from typewriting, restaurant orders, mental arithmetic, computer programming, judicial decision-making, and medicine. The overview chapter listed seven primary attributes that characterize the performance of most experts across domains. These observations have helped to shape the development of the field:

1. Experts excel mainly in their own domains;
2. Experts perceive large meaningful patterns in their domain;
3. Experts are fast; they are faster than novices at performing the skills of their domain, and they quickly solve problems with little error;
4. Experts have superior short-term and long-term memory;
5. Experts see and represent a problem in their domain at a deeper (more principled) level than novices; novices tend to represent a problem at a superficial level;
6. Experts spend a great deal of time analyzing a problem qualitatively;
7. Experts have strong self-monitoring skills.

When performing in their domains, experts rely on their highly refined mental models to represent and solve the problems they encounter. These schemas allow experts to identify the problem type and respond using efficient and effective strategies that leverage their deep understanding of the problem structure (Chi, Feltovich, & Glaser, 1981). Using known strategies, they are able to proceed directly toward the desired outcome. Referred to as "forward reasoning," this process differs sharply from novices' approaches to problem solving, which typically involve reasoning backward from the desired outcome to identify appropriate intermediate steps (Chi, Glaser, & Rees, 1982).

In addition to these characteristics, studies from various domains suggest that experts typically have at least 10 years of experience in their fields. In a major review of the research, Ericsson and his colleagues (Ericsson, Krampe, & Tesch-Römer, 1993) analyzed many

studies of training outcomes across a wide range of tasks (e.g., Morse Code operation, musical performance, Olympic sporting events) and found strong evidence that years of experience alone was not sufficient for explaining performance outcomes. Replicating these findings, their own study demonstrated that in some cases expert professional pianists had up to six fewer years of experience than their less-skilled amateur counterparts.

To explain this discrepancy, Ericsson proposes that those individuals who become experts engage in focused and intensive training during their years of experience known as *deliberate practice* that is qualitatively different than other types of experience within the domain. Defined as “the individualized training activities especially designed by a coach or teacher to improve specific aspects of an individual’s performance through repetition and successive refinement [that includes] monitor[ing] their training with full concentration, which is effortful and limits the duration of daily training” (Ericsson & Lehmann, 1996, pp. 278–279), deliberate practice is not considered to be inherently motivating. It is specifically intended to refine performance and remediate any facet of relevant skills in which there is room for improvement (Ericsson & Charness, 1994).

Ericsson characterizes experts’ performance as demonstrating maximal adaptation to task constraints. In simpler terms, this means that experts have shaped their skills to maximize the efficiency of their actions within the structural context of their domains as they solve relevant problems. Such adaptations can take the form of “shortcuts” that would not be feasible for non-experts but produce superior results when employed appropriately. For example, expert athletes learn to anticipate changing conditions rapidly and respond effectively before the new condition has actually formed (e.g., anticipating the gunshot that starts a race). Likewise, chess masters can visualize the ways in which a particular move may prevent or allow an opening several moves later in a game and make preemptive decisions on that basis.

When task constraints change, however, some experts are unable to adapt successfully to the new situation while others retain their high levels of performance. Giyoo Hatano (1936–2006) characterized members of these respective groups as *adaptive* and *routine* experts (Hatano, 1982). Adaptive experts typically understand why their skills are effective under normal circumstances and successfully modify them to fit the new situation or invent new procedures as necessary (Hatano & Inagaki, 1986, 2000). However, it is challenging to reliably identify adaptive experts. Studies of expert bridge players, electronics troubleshooters, and others have found that changing task constraints (e.g., point values in bridge) or introducing highly unusual situations often leads to weak performance by

EXPERTISE AND IQ

Expertise is often attributed to high levels of intelligence. However, studies of expertise consistently find that there is no correlation between IQ and experts’ performance. Ericsson (1998; Ericsson & Charness, 1994; Ericsson & Lehmann, 1996) investigated reports of child prodigies who are reputed to perform feats rivaling top experts’ abilities. However, in instances where these abilities have been sufficiently documented to permit independent validation, the prodigies consistently have approximately 10 years of deliberate practice that was initiated and supported by parents, tutors, or coaches as young as 18 months old. The available evidence indicates that even those abilities typically attributed to innate talent (e.g., perfect pitch, exceptional memory, reflexes, muscle strength and endurance, etc.) can be fostered through environmental factors and training experiences for children who are highly motivated to succeed in these tasks.

individuals who typically demonstrate high levels of expertise in their domains under routine conditions.

DIFFERENT PERSPECTIVES ON THE DEVELOPMENT OF EXPERTISE

As discussed above, Ericsson’s findings across domains indicate that world-class performers tend to require about 10 years of deliberate practice prior to attaining that status. However, other research from various fields suggests that other factors may also play a role. Dean Keith Simonton (1948) argues that those experts who demonstrate adaptive expertise through creative innovations in their respective fields typically score higher on personality measures of nonconformity, independence, openness to experience, ego strength, introversion, and aggressiveness. They are also significantly more willing to take risks than routine experts in their fields (Simonton, 1999, 2000). Additional research also suggests that highly creative experts tend to have broader interests than their less creative counterparts (Simonton, 1976).

Simonton’s analyses also indicate that several assumptions of the deliberate practice hypothesis are not borne out with regard to experts in creative fields like music composition and scientific discovery. He argues that if deliberate practice were the sole factor affecting the development of expertise, then the best

experts ought to be those with the most years of deliberate practice. However, his (1991a, 1991b) studies of 120 classical composers and 2,026 scientists and inventors indicated that those who were most productive and considered to be most eminent in their respective fields trained for fewer years and made major contributions sooner after their first accomplishments than those considered to be less important contributors. Further, the career trajectories of creative experts tend to peak and then decline, despite ongoing deliberate practice, and the odds of generating a creative success do not change significantly over the course of a career (Simonton, 1985, 1986, 1997).

Ericsson (1998, 2004) suggests that practice which becomes rote rather than deliberate may limit the development of expertise in this way. Research in cognitive skill development indicates that as people practice new skills, they typically require less and less conscious attention directed to their actions while maintaining a consistent level of performance. For example, learning to read or drive a car is typically highly effortful, slow, and halting when it is first learned. However, with continued practice, performance becomes fluent with little or no attention directed to the component skills (e.g., pronunciation or word recognition during reading; shifting gears or stepping on the brake pedal while driving). This *automaticity* of skills results in performance that is very fast and consistent. It may also lead to people being unaware of how they perform those skills and even whether or not the skills were used in a particular situation. As skills automate, they demand fewer cognitive resources, so attention can be redirected to other tasks.

What is done with surplus attention during practice and performance is likely a critical factor in the development of advanced and creative expertise. In deliberate practice, this attention is reinvested to continually monitor and improve performance. However, when spare attention is allocated to unrelated activities (e.g., talking on a cellular phone while driving), skill development plateaus.

For this reason, Ericsson argues that automaticity should be avoided as individuals seek to become experts. However, research on skill acquisition and expertise from cognitive science indicates that automaticity in fundamental domain skills is necessary to make available the attentional resources required to develop and execute more sophisticated strategies. Spare attention during performance is especially important for adaptive experts, because they must allocate their cognitive resources to recognizing and understanding novel or unusual aspects of a task and the implications of resulting atypical constraints. Therefore, those routine skills that are directly applicable to the new task must not demand conscious attention that would compete with these needs.

David Feldon (1975) suggests that what differentiates adaptive experts who are able to leverage their automaticity from routine experts whose flexibility is limited by it is the number and relevance of the decision points in their procedures (Clark, Feldon, van Merriënboer, Yates, & Early, 2008; Feldon, 2007a). As skills automate and basic skills combine to form more complex procedures, consciously mediated decision points remain where details of the specific situation determine which of several possible strategies will be the best to employ from an expert's repertoire in that instance. Thus, the training most likely to lead to adaptive expertise presents learners with a wide variety of practice scenarios to support the development of appropriately placed decision points and to avoid inappropriate automatization of requisite skills (Clark, Feldon, Howard, & Choi, 2006; Feldon, 2007b).

IMPLICATIONS OF RESEARCH ON EXPERTISE FOR INSTRUCTION

Conventional wisdom suggests that if a learner needs to know how to do something well, the best instructor would be an expert in the field. However, research indicates that this is not always the case. Trends in the findings on experts' instructional abilities indicate that, overall, experts are (1) inaccurate in their assessments of learners' knowledge and abilities relevant to learning procedures in an expert's field, and (2) inaccurate in their explanations of how they accomplish tasks within their domains.

Pamela Hinds' studies of experts as instructors demonstrate that experts are significantly worse than non-experts in predicting the amount of time that it would take novices to learn presented material within the experts' domain of expertise. Further, debiasing techniques that are often effective in improving the accuracy of non-experts' preliminary assessments of novices did not improve their predictions (Hinds, 1999). In another study, Hinds compared the efficacy of one-on-one instruction between novices and experts with one-on-one peer instruction among novices. She found that when novices taught other novices how to perform a task, the students were better able to perform the procedure correctly than when experts provided the instruction. However, if the novice learners were asked to complete a task that required adjustments to the procedure that was taught, those who learned from the experts performed better (Hinds, Patterson, & Pfeffer, 2001).

These findings indicate that the explanations of experts offer an advantage, because their sophisticated mental models of their domains allowed them to structure the information that they provided to be broadly applicable. This differed from the overly specific explanations of novices, which were based solely on their experiences with the single task in the study. However, it seems that experts

excluded specific information which would have been helpful to learners as they attempted to perform the task. This may have occurred (1) because the experts overestimated learners' pre-existing knowledge bases, (2) because they could not successfully explain the automated skills they themselves use, or (3) for a combination of both reasons.

Feldon's investigations of experts' self-report accuracy (2004, 2007a, 2007c) indicate that automaticity does play a role in limiting their abilities to fully describe their own problem-solving processes. Analysis of experts' explanations of their actions during a recorded task revealed that inaccuracies represented both omissions of relevant steps in their activities and statements that directly contradicted their actions. If the only reason for experts' inaccurate explanations was an overestimation of students' abilities, then only errors of omission would be expected. However, the presence of errors of commission indicates that experts' may lack an awareness of their own actions that would limit the accuracy and completeness of their explanations to others.

Research on ways to maximize the benefits of experts' knowledge for instruction has identified techniques that appear to avoid the limitations of experts' limited self-awareness within their domains. Collectively known as *cognitive task analysis* (CTA), these techniques involve intensive, highly structured interviews with multiple experts to identify and collectively validate complete explanations of effective ways to perform a specific task within the domain of expertise. Instructors then incorporate these protocols into their course materials to supplement or replace their own explanations of the skills to be learned. Controlled studies of CTA-based instruction consistently demonstrate dramatic effect sizes favoring its use over more traditional unscaffolded explanations by experts in diverse domains including medicine, electronic systems troubleshooting, and spreadsheet applications (Clark et al., 2008; Feldon, 2007a; Feldon & Clark, 2006).

F

FEEDBACK IN LEARNING

Feedback occurs when the output of a system becomes an input to the same system, causing the system to respond dynamically to its previous productions. In learning, feedback can occur when consequences or products of a learner's behavior or cognition indicate the degree to which a goal or expectation is left unmet. Such information allows learners to check and improve the quality of their understanding, their application of knowledge and skill, and the processes by which they acquire new capabilities. In order for the consequences of behavior or cognition to influence further learning (and thus operate as feedback), at least three conditions must be met:

- A learner with implicit or explicit learning goals or expectations
- An environment that makes the consequences of action or cognition observable
- The ability of the learner to note and interpret the consequences of action or cognition.

In educational contexts, feedback appears in various guises, often tailored by an agent in the learner's environment with the specific intent of altering or nurturing some aspect of the learning process. In interpersonal interactions, feedback can appear in dialogues between a teacher and student or in the discourse of students engaged in collaboration. Feedback can be a smile or a frown, verbal corrections and explanations, or a display of expert performance after a novice attempt. A teacher can provide feedback to students about whether specific performance

criteria have been met in formative assessments. Feedback can appear in myriad mediated forms—paper-based workbooks and programmed instruction, computer-based tutorials, and computer-based simulations—where students check their answers or study informative consequences (e.g., the correct answer, suggestions for improvement, and simulation results). Many inquiry and project-based educational programs rely on learners to test hypotheses and gain new knowledge from analysis of experimental results. The capable, independent learner can find feedback in all sorts of interactions with the learning context if the learner has clear goals and expectations and abilities to perceive and interpret relevant consequences of action and cognition.

A BRIEF HISTORY OF FEEDBACK

In the early twentieth century, the term *feedback* referred to electrical systems used in audio broadcast. For example, feedback was brought to public attention in a notorious series of lawsuits over a patent for a circuit that would amplify radio signals by feeding back the signal into the circuit in rapid oscillations. Engineers came to use feedback to refer to products of a mechanical or electrical system that allowed the system to regulate itself. For example, if a heating system warms air temperature beyond a specified point, a thermostat can switch the system off and restart the heating system once the air temperature cools. Feedback became an explicit and crucial engineering concern as industry and the military sought to increasingly automate during World War II.

In 1948 *Cybernetics: Control and Communication in the Animal and the Machine*, by Norbert Wiener (1894–1964) made an enormously influential articulation of the role of

feedback in the operation of all varieties of mechanical, biological, psychological, and social systems. Coining the term cybernetics from the Greek for *steersman*, Weiner conceived of a new science to investigate how feedback and information dissemination regulate systems. With ideas both persuasive and prescient, Weiner imagined how feedback systems could be linked to complex calculating machines to create mechanical brains that demonstrate artificial intelligence, the machine learning and action that is responsive to dynamic features of a changing environment.

Simultaneous with conceptualizations of feedback in engineering, behaviorism emerged as a psychological paradigm which emphasized the consequences of an organism's behavior as the primary determinant of future behavior. Simply put, behaviorism argued that certain behavioral consequences act as reinforcers, increasing the subsequent frequency of behaviors that produce them. A child might increase, for example, the frequency of behaviors that lead to acquiring candy. Some consequences act as punishment, dramatically reducing the frequency of a behavior that produces them. Without reinforcing or punishing consequences, a behavior extinguishes, diminishes to some baseline frequency.

However, behaviorism struggled to account for the operation of some behavioral consequences and learning phenomena. How might it explain behaviors that persist in spite of punishment or which seem indifferent to reinforcement? How might behaviorism account for one-time learning and sudden insight, early acquisition of the grammar of a language, creativity, and actions that seem guided by abstract concept, not perceptible stimuli? Such phenomena implied the operation of some mental apparatus that could perform interpretative transformations on stimuli and produce new capabilities that are not so directly derived from simple behavior-consequence contingencies.

The combined influence of the cybernetics paradigm, weaknesses in behaviorism's account of learning, and developments in computer technology made psychology and education ripe for a so-called cognitive revolution. A new paradigm of humans as processors of information, borrowed from computing, supplanted behaviorism. Perceptible stimuli were no longer only considered cues or consequences for behavior, but informative signals that could be interpreted by mental apparatus, stored in meaning-preserving ways in memory, and used to inform future goal-directed action. The consequences of that action could then be fed back into the interpretive mental processor.

CONTEMPORARY VIEWS OF INSTRUCTIONAL FEEDBACK

At the beginning of the twenty-first century, the information-processing paradigm still provides a standard conceptualization of instructional feedback. For example, for

the influential instructional psychologist, Robert Gagné (1916–2002), learning is the encoding of information from short-term into long-term memory storage. In subsequent practice, newly stored knowledge is retrieved and applied. Feedback, the consequences of knowledge applications, re-enters the cognitive system, causing potential alterations in goals, learning processes, and stored knowledge.

Feedback's conceptualization has evolved in two significant ways. First, the source of feedback is no longer presumed to be a teacher or even external consequences. Butler and Winne, for example, emphasize the importance of internal sources of feedback generated through self-monitoring as a critical engine of self-regulated learning. In the absence of teacher-provided feedback, capable learners could interpret the consequences of their actions and cognitions in light of learning goals and thus provide feedback to themselves.

Second, some researchers distinguish among types of feedback. Bangert-Drowns, Kulik, Kulik, and Morgan suggested that feedback can provide information about knowledge retrieval and application, emotional and motivational states, and strategic management of learning. It could indicate whether a performance is correct, explain the nature of an error, provide prototypical responses, or simply display the consequences of actions. Each of these likely requires different features to be optimally effective. Hattie and Timperley, extending Kluger and DeNisi's suggestion that feedback loops can be hierarchically nested one in another, proposed four levels of feedback: about the quality of task performance, about the cognitive processes used to accomplish the task, about the ways in which a learner could better manage learning engagement, and about the self. Evidence suggests that these different kinds of feedback will be differentially effective according to different standards; for example, information about the self may not provide effective performance enhancements because it does not indicate specific ways in which knowledge or learning processes can be adjusted.

OPTIMIZING FEEDBACK FOR LEARNING

Feedback in learning is difficult to research. It has been found to inform learners about the following:

- The accuracy or efficiency of knowledge and its retrieval or application
- The quality of mental operations applied to information
- The quality of psychomotor performance
- The viability of a hypothesis or expectation
- The emotional or motivational state of the learner

- The efficiency or quality of learning processes employed in a learning task
- The management of learning processes
- Enduring qualities and goals of self
- The nature of relationships with co-learners and teachers.

Different feedback features might be differentially effective for different learners and different aspects of learning. Even apparently straightforward feedback depends on the interpretation of a learner. A learner could interpret the response “incorrect” as indicating a need to revise knowledge, a personal rejection, the confirmation of a hypothesis, or a hint to work harder.

Despite these difficulties, some generalities about feedback effects are possible. Kulhavy suggested and Bangert-Drowns, Kulik, Kulik, and Morgan supported that if feedback is available before a learner actively attempts to perform a task (presearch availability), the learner may not be cognitively and motivationally prepared to effectively use the feedback. Kulhavy also suggested and subsequent research corroborates that response certitude, the degree to which learners feel most sure of their knowledge, makes disconfirming corrective feedback more salient and thus more influential in learning. Kluger and DeNisi suggest that feedback most effectively enhances performance when it directs attention to motivational and task-specific goals, not self-related goals. Research on the timing of externally provided instructional feedback immediate or delayed after some learner performance has yielded highly varied results. Hattie and Timperley suggest that this variation might be accounted for by level of feedback; immediate task feedback might most benefit task performance, but delayed processing feedback might most enhance cognitive processing of information.

Clearly, feedback is a critical, ubiquitous, and complex feature of learning processes guided by teachers or directed by learners themselves. Educators would do well to create environments that support challenging standards and goal-setting and provide informative feedback. Students can also benefit from assistance regarding how to look for and use feedback and how to provide feedback for themselves. Future research will continue to clarify conditions that optimize feedback effects for different tasks and learners.

Robert L. Bangert-Drowns

FIRST (PRIMARY) LANGUAGE ACQUISITION

The term *first language acquisition* refers to children's natural acquisition of the language or languages they hear from birth. It is distinguished from second language acquisition, which begins later, and from foreign language learning, which typically involves formal instruction.

First language acquisition is a rapid process. In the span of just a few years, newborn infants who neither speak nor understand any language become young children who comment, question, and express their ideas in the language of their community. This change does not occur all at once. First, newborns' cries give way to coos and babbles. Then, infants who coo and babble start to show signs of comprehension such as turning when they hear their name. Infants then become toddlers who say “bye-bye” and “all gone” and start to label the people and objects in their environment. As their vocabularies continue to grow, children start to combine words. Children's first word combinations, such as “all gone juice” and “read me,” are short and are missing parts found in adults' sentences. Gradually children's immature sentences are replaced by longer and more adultlike sentences. As children learn to talk, their comprehension abilities also develop, typically in advance of their productive speech. As children master language, they also become masters at using language to communicate. One-year-olds who can only point and label become 2-year-olds who comment,

question, and command, and 4-year-olds who can carry on coherent conversations. Studies of middle-class, typically developing children acquiring English have documented that by four years of age children are nearly adult like in phonological properties of their speech; they have vocabularies of several thousand words, and they produce most of the types of structures observable in the speech of adults (Hoff, 2008).

THEORIES OF FIRST LANGUAGE ACQUISITION

First language acquisition is a robust process. Despite differences among cultures in the kind of early language experience provided to children, all normal children in anything remotely approximating a normal environment learn to talk (Hoff, 2006a). The rapidity and robustness of first language acquisition, along with its status as an accomplishment unique to humans, suggests to some that first language acquisition is supported by language specific innate knowledge. Language, according to this view, is encoded in the human genome—as are stereoscopic vision and bipedal locomotion. Another argument for the position that language has significant innate support comes from analyses of the nature of language knowledge in both the adult and child. Once language is acquired, speakers and hearers have the capacity to produce and understand an infinite number of novel sentences. This productivity of language poses a challenge to efforts to account for language acquisition on the basis of experience. Somehow children go beyond what they have experienced and construct a grammar that allows them to produce an infinite number of different sentences from a finite inventory of words. The argument for innate linguistic knowledge is also supported by evidence that very young children are sensitive to structural properties of language for which there is no obvious explanation in terms of infants' experience (Lidz, 2007).

INFANT ATTENTION TO AND RECOGNITION OF ENVIRONMENTAL SPEECH

Although it is not possible at this point to fully explain how language could be acquired without language-specific innate knowledge, there is mounting evidence that children can and do learn a great deal from their environments. Infants come to the language learning task equipped with attentional biases and learning capacities that operate on the experience their environments provide. Infants are biased to attend to speech over other environmental noises, and they pay particular attention to speech that has the exaggerated rhythm and intonation contour that characterizes the speech addressed to infants. Infants are excellent at extracting patterns from input, and this capacity for what is

termed statistical learning may make a substantial contribution to the language acquisition process (Gerken, 2007). For example, infants learn which acoustic features tend to co-occur in the speech they hear, with the result that their speech perception becomes tuned to the particular speech sounds used in the language they hear (Maye, Werker, & Gerken, 2002). A side effect of this tuning to the native language is a decline in the ability to hear sound contrasts that are not used in the ambient language. Thus, the basis for the foreign accent that is characteristic of late-acquired second languages is laid in infancy (Kuhl, Conboy, Padden, & Pruitt, 2005).

Infants also detect patterns among speech sounds. In experimental testing, it has been demonstrated that eight-month-old infants can detect patterns of co-occurring syllables in a stream of sound that they were exposed to for only two minutes (Saffran, Aslin, & Newport, 1996). These pattern learning abilities allow infants to recognize many familiar sound patterns in their language before they have learned the meanings associated with them. By nine months, infants have learned that some sound sequences are typical of their language and others are not. For example, American and Dutch nine-month-olds can discriminate English from Dutch words based on differences between them in what are allowable sound sequences (Jusczyk, Friederici, Wessels, Svenkerud, & Jusczyk, 1993; Gerken & Aslin, 2005).

Pattern learning may also provide children the basics of grammar. In experimental testing, 1-year-old children have demonstrated the ability to learn the patterns among words in word strings that they hear such that they later can distinguish sequences that violate this pattern from other sequences that are grammatical (Gomez & Gerken, 1999). It has been suggested that children may also learn the grammatical categories of their language (e.g., noun and verb) by noticing distributional regularities (e.g., all the words that are nouns are frequently preceded by “the”). Noticing co-occurrences also is one source of information about word meanings. When children hear the same word in many different contexts, they can use information about what is constant across those situations to narrow down the possible meanings of the word.

USING A COMMUNICATION SYSTEM TO MAKE CONTACT

Language acquisition is not solely a matter of learning the sounds, the words, and the grammar of language. In acquiring language children acquire a system that is used to communicate. Human infants are social beings, and the basic human desire to make contact with others is part of the foundation of language acquisition. (Children with autism seem not to have this desire to the same degree as typically developing children, and this difference is thought to be one root of the language disturbances that are characteristic of autism.) An important

Reading to a child encourages language development. © BRIAN MCENTIRE, 2008. USED UNDER LICENSE FROM SHUTTERSTOCK.COM.

social-cognitive ability that contributes to communicative interaction and to language development is the capacity for joint attention. Around the age of 10 months, children become able to actively engage their parents (and other individuals) while simultaneously focusing on an object of interest. In the first two years of life, language interaction that occurs in episodes of joint attention seems to be particularly useful to the language learning process (Baldwin & Meyer, 2007). More specifically, children as young as 18 months can use speakers' eye gaze as a clue to the referent of the words the speaker is producing. Children's non-linguistic, cognitive understandings also support word learning because a great deal of word learning consists of mapping sound sequences onto concepts children already understand nonlinguistically (Poulin-Dubois & Graham, 2007).

Many properties of children's language learning experience support the process of language acquisition. When

adults (and older children) talk to infants they speak more slowly, clearly, at a higher pitch, and with exaggerated intonation. This special register for talking to children has been called *motherese*. Infants have been shown to prefer to listen to motherese over adult-directed speech, even when the speech is in another language. The properties of motherese may also be beneficial for language acquisition. Vowel sounds are more consistent in infant-directed speech, and the stress patterns that indicate word and phrase boundaries are exaggerated. Mothers and other adults also tend to provide labels and information about things that they present to children, which aids children in vocabulary building. Infant and child-directed speech is characterized by repeating and expanding on the words and phrases children produce, which also may help children learn word meanings and sentence structure (Hoff, 2008).

FACILITATING FIRST LANGUAGE ACQUISITION

Although all normal children acquire language, there are large individual differences in the rate at which children acquire language and therefore in the language skills children possess when they enter school (Hoff, 2006b; 2006c). These individual differences in oral language skill are predictive of success in acquiring literacy. Some of these individual differences may be the result of differences among children in language learning ability, but to a significant degree, variance among children in their language skills reflects variability in the language learning experiences they have had (Hoff, 2003a). Studies of children within the United States have shown that children who experience more one-to-one conversation with adults have more rapid language development. Thus, a supportive environment for language acquisition is one that is characterized by a great deal of verbal engagement with the child (Huttenlocher et al., 1991; Hart & Risley, 1994). The quality of the speech children hear also matters.

Contrary to the view that children require simple input, speech that uses a rich vocabulary and long, information-containing utterances has been found to promote language development (Hoff & Naigles, 2002; Pan, Rowe, Singer, & Snow, 2005). Children who hear a more diverse vocabulary develop larger vocabularies themselves even at age 2 (Hoff & Naigles, 2002; Pan et al., 2005). Thus, successful and optimal language acquisition is contingent upon the richness of language input a child is exposed to. In addition, grammatical development seems to be accelerated when child-directed speech repeats and expands on a phrase or utterance a child attempts to produce (Hoff-Ginsberg, 1985, 1986). Studies of children in the United States suggest that book reading with an adult is a positive activity that provides children with a great deal of language input. Studies show that mothers produce more speech during book reading time than during toy play time, and this speech is richer than that produced during play time. Object labeling is also frequent during book reading, which may facilitate lexical development (Hoff, 2003b).

BILINGUAL FIRST LANGUAGE ACQUISITION

First language acquisition can be the acquisition of more than one language. The term bilingual first language acquisition has been used to refer to the circumstance in which a child acquires two languages from birth (Genesee & Nicoladis, 2007). (There has been very little research on the acquisition of more than two languages.) In the case of bilingual first language acquisition, the course of language development is largely unaffected by bilingualism. Infants seem to have the ability to distinguish two different types of

sound streams based on the acoustic characteristics of the languages, and they are able to build two separate language systems. The rate of development in each language depends on the amount of exposure children receive. Typically, bilingually developing children show more rapid development in the language that they hear more (Pearson, 2008).

In sum, the human infant brings a social inclination, powerful learning abilities, and perhaps language-specific innate knowledge to the language learning task. In order for language acquisition to occur, the environment must meet those abilities by providing children with communicative experience. Linguistically rich and responsive communicative environments promote optimal language development.

FLOW THEORY

Flow theory was proposed by Mihaly Csikszentmihalyi to describe the experiences of intrinsically motivated people, those who were engaged in an activity chosen for its own sake (Csikszentmihalyi, 1975, 1997). Such activities were viewed as worth doing just for the sake of doing them rather than as means to another end. While other research on intrinsic motivation focused on behavioral outcomes, Csikszentmihalyi attempted to describe the quality of subjective experience, or how intrinsic motivation felt. Further, he sought to explain the characteristics of activities that people were intrinsically motivated to pursue, and why such activities were rewarding.

Under certain conditions, people's experiences are optimal. Csikszentmihalyi (1975, 1997) and his colleagues, Rathunde, Whalen and Nakamura, defined optimal experiences as those that were accompanied by a merging of action and awareness, strong concentration on the task at hand, and a loss of awareness of time. At such times, people concentrate

so hard on the current task that they forget about time and the world around them: They are thoroughly engrossed. Further, these activities are accompanied by positive emotions. They termed this quality of experience "flow."

The experience of flow is possible under certain circumstances: when individuals find the activities challenging and also believe they have the skills to accomplish them. Optimal experience, or flow, occurs when a person perceives the challenges in a certain situation and the skills brought to it as both balanced and above average. In contrast, when challenges and skills are unbalanced, such as when challenges outpace skills, an activity could evoke anxiety. The various ratios of challenges and skills are predicted to be associated with different qualities of experience: flow with high challenges and skills, apathy with low challenges and low skills, anxiety with high challenges and low skills, and boredom or relaxation with low challenges and high skills. The original classification scheme based on level of challenge and skill, described above (flow, relaxation, anxiety, and apathy) has been further refined into an eight-category scheme, and a twenty-four-category scheme. All schemes are based on the tenet that levels of challenge and skill interact to affect the quality of experience.

The idea of optimal challenge is not new to the field of education. Indeed, both Lev Vygotsky, a Russian psychologist (1896-1934), and Jean Piaget, a Swiss psychologist (1896-1980), contended that learning best occurs when people engage in activities that are at the peak of their abilities, when they have to work to their full potential to accomplish a task. However, the study of the experience of optimally challenging activities and the method of study are unique to flow theory.

MAJOR RESEARCH METHODS

Flow theorists not only study those who are intrinsically motivated to participate in an activity, but also individuals engaged in everyday activities. Csikszentmihalyi developed the Experience Sampling Method (ESM) to explore how individuals experience activities throughout their daily lives. The ESM involves randomly alerting individuals to answer questions about what they are currently doing, as well as their emotions, motivation, concentration, and thoughts associated with the task. Alerting methods have included beepers, watches, or PDAs set to randomly alert throughout a given time period. In this way, researchers can gain access to the thoughts and feelings during an activity as individuals are engaged in it. Other methods require individuals to recall how they felt or what they were thinking during prior activities, relying on memory.

The standard use of the Experience Sampling Method is to electronically beep students randomly during the day and ask that they complete a questionnaire (the Experience

Sampling Form, ESF, validated by Csikszentmihalyi and Larson). The first items on the ESF ask individuals to describe the activity in which they are currently engaged, followed by a series of questions to assess levels of motivation, cognition, and affect associated with the activity. These are Likert-type items (in which responses can range from 1 = not at all to 9 = very much) that resemble, for example: “Was this activity important to you?” “How hard were you concentrating?” “How do you feel about the challenges of the activity?” “How did you feel about your skills in the activity?” An additional thirteen semantic-differential items measure emotion during the activity (e.g., happy-sad, excited-bored, and sociable-lonely). Each activity can then be classified into the flow categories as determined by the level of perceived challenge and skill above or below average.

With such a method, researchers are able to determine (a) the amount of time spent in different types of activities throughout a day, week, or month, (b) which individuals spent more or less time in certain activities, (c) how different activities were experienced (both cognitively and emotionally) and which were most or least enjoyed, (d) characteristics of the environment or context that best contribute to optimal experiences and (e) which individuals were more likely to enjoy different activities.

While this method is often used to gain an understanding across all the activities in everyday life, some researchers have specified the types of activities they want to study. For example, some researchers, such as Schweinle and colleagues and Shernoff and Hoogstra, have limited the random alerts to times when participants are in school or completing homework. In this way, they gain information about the experience of different school and homework activities, such as whole-class instruction, group projects, watching videos, taking tests or quizzes, etc.

One drawback to the ESM is that it can be expensive and time consuming. Further, it requires using a large number of participants to get a broad range of experiences. It is also difficult in educational settings where teachers may not be amenable to some students randomly stopping their activity to complete questionnaires. Some researchers have adapted the ESM to assess the experience of specific activities without random beeps. For example, Schweinle and colleagues were interested in elementary students’ experience of mathematics classes. Rather than beeping students randomly throughout their math classes, they asked students to complete ESFs at the end of twelve different math classes across a school year. This type of method provided information specific to activities during math class rather than a cross-section of activities in everyday life. One drawback, though, was that it required students to recall their math class and respond with a general sense of how they experienced the whole class rather than specific points throughout the math class. Using the tradi-

tional ESM or modified versions, researchers have learned about how students experience school and academic activities and the environments that contribute to the most optimal academic experiences.

FACTORS INFLUENCING FLOW AND MOTIVATIONAL CONSEQUENCES

One benefit of flow theory is that it presumes that motivation, cognition, and affect are situational. Whereas much research in motivation has focused on relatively decontextualized individual psychological processes, flow theory presumes that these psychological processes are made meaningful by the environment. The ESM allows for study of both the environment and the persons within the setting. For example, researchers have used the ESM to determine how students spend their days and how they experience those activities. In one study, Shernoff, Knauth, and Makris found that high school students spend most of their classroom time paying attention to the teacher lecture (23%) or performing individual tasks such as writing notes or completing homework assignments (23%). Only about 8% of students’ time was spent in interactive activities, including classroom discussion (5%) and group tasks or laboratory experiments (3%). In short, students were engaged in intellectually challenging tasks for more than half of the day; however, roughly one-third of their time was spent passively listening to the teacher lecture or observing a video.

Using the ESM, Shernoff and colleagues were also able to determine the quality of the students’ experiences while engaged in each of these activities. Specifically, while students enjoyed watching videos and TV in class, they viewed these activities as the least challenging. Students also enjoyed individual work, which they reported most positively in terms of academic challenge, affect, control, and motivation. Lecture was viewed as unchallenging and was met with negative affect and lower levels of control. Considering that students spend approximately one-third of their time in the classroom passively listening to teachers or video, students may not be adequately challenged or motivated to learn.

Further, researchers have examined the quality of the experience as it relates to the balance of the challenge and skill of the activities. Researchers have for years extolled the benefits of high challenge matched with skill level, or optimal challenge. Vygotsky explained that the highest levels of learning occur when students are pushed to perform just beyond their current ability levels. As their skill levels increase, so must the level of challenge, maintaining an optimal balance that encourages continuous learning.

Flow theory further contends that, not only do activities with high challenge matched with high skill offer the best opportunities for learning, but they also provide an optimal environment for positive affect and intrinsic motivation. (It should be mentioned that not all activities with high challenge and high skill elicit flow states. However, flow states can only occur when high challenge is coupled with high skill.) If students believe that they have the skills to produce the desired results, positive affect is more likely to be experienced. When challenges and skills are optimal and balanced, students can experience higher levels engagement, attention, concentration and interest, according to Shernoff and his colleagues, as well as higher levels of positive affect, interaction with the class, efficacy, and value of the material, according to Schweinle and her colleagues (2006).

Interestingly, it is still possible to have positive affect if skill exceeds challenge. In fact, Schweinle and colleagues (in press) found that a student's skill level, rather than the perceived challenge of the activity, was the most significant factor in predicting positive affect and efficacy. While students may feel more positive if they believe they can succeed whether or not the challenge is high, only activities with high levels of challenge will also provide opportunities to learn. Phrased another way, students must have high to moderate levels of efficacy to demonstrate a preference for challenge. Teachers can use these tenets of flow theory to provide for optimal learning as well as positive affect and motivation to learn.

IMPLICATIONS FOR TEACHERS

Teachers encourage flow and intrinsic motivation by creating an environment that fosters enjoyable learning experiences. Ideally, to encourage optimal experiences, teachers must provide optimal challenge and support for competence (or skill). Schweinle and colleagues also found that, in classrooms where students reported high positive affect, efficacy and value of the material, teachers balanced levels of challenge and skill as well as (a) provided immediate, constructive feedback, (b) encouraged students to persist, (c) encouraged cooperation rather than competition, (d) supported student autonomy, (e) ensured that new challenges were tempered with support to match students' skill, (f) emphasized the importance of the material, and (g) pressed students to understand the principles rather than memorize algorithms.

Csikszentmihalyi (1997) argues that when teachers provide immediate, informational feedback regarding student performance, students become more interested and persistent with goal setting. Additionally, intrinsic motivation and self-efficacy increases in students. If a student receives non-constructive feedback, such as evaluating an individual's trait, motivation will decrease and negative affect may occur.

In addition to providing effective feedback, teachers can also increase intrinsic motivation and classroom experience by supporting student autonomy. Students become more involved when instructional activities are perceived as important and when students perceive themselves as autonomous and in control over their environment, according to Shernoff, Schneider, and Csikszentmihalyi. Schools can promote autonomy by minimizing external controls to facilitate conceptual understanding, allowing students to set goals and choose their own activities. In such a way, students are more likely to feel in control of their goals. However, if teachers provide a controlling environment by inflicting deadlines, stressing grades and performance, and demanding specific solutions rather than creativity, a decrease in affect, interest, and motivation could occur.

Positive affect may be one of the most powerful predictors of intrinsic motivation. Humor, expressions of enjoyment towards the subject matter, and utilizing kindness and sensitivity can produce a positive atmosphere in the classroom. In contrast, if teachers use threats, sarcasm, and directives, students may become less motivated and may experience negative affect. In addition to providing a positive atmosphere, teachers should also encourage social relationships. Schweinle's research suggests that teachers who allow students to work with their peers will help build cooperation in the classroom and an increased commitment and interest in the subject matter.

Challenge and feeling competent are important for optimal experiences. Teachers support this when they use students' errors as learning opportunities and provide chances for students to show their skill levels. The students' skill levels should match the challenge of class activities to encourage flow experiences. The difficulty level of tasks should increase as student skills increase. If a student maintains low skills and perceives the task as highly challenging, then the student may become anxious and experience negative feelings. To provide an ideal level of challenge, teachers can scaffold tasks, provide adequate time for students to complete tasks, and reduce long-term goals into smaller units, which follows Vygotsky's principles. This could increase the enjoyment of math, lessen anxiety, increase feelings of success, and ultimately create an environment conducive to optimal experiences.

Optimal experience in classrooms is important for students' learning and motivation at the present and also for their future educational plans. Shernoff and Hoogstra found that when students experience cognitive and emotional engagement with a specific topic, the resulting feelings may guide post-high school plans, such as college courses or majors. Further, interest and enjoyment with

certain topics were essential factors for highly engaged students when making career decisions.

In sum, flow theory addresses how students experience educational contexts and how this experience influences learning and motivation. Activities that challenge students, but are still within their ability to accomplish, set the stage for optimal emotional and motivational experiences as well as optimal learning. Within the context of balanced challenge and skill, teachers can also improve the chances of positive experience by supporting autonomy; providing immediate, constructive feedback; encouraging cooperation among students; supporting positive affect; and pressing understanding rather than rote learning.

FORMATIVE AND SUMMATIVE ASSESSMENT

Assessment is the use of a variety of procedures to collect information about learning and instruction. Formative and summative assessment represent two classifications of assessment, each with a distinct purpose. Formative assessment is commonly referred to as assessment for learning, in which the focus is on monitoring student response to and progress with instruction. Formative assessment provides immediate feedback to both the teacher and student regarding the learning process. Summative assessment is commonly referred to as assessment of learning, in which the focus is on determining what the student has learned at the end of a unit of instruction or at the end of a grade level (e.g., through grade-level, standardized assessments). Summative assessment helps determine to what extent the instructional and learning goals have been met. Formative and summative assessment contribute in different ways to the larger goals of the assessment process.

PROCEDURES USED IN FORMATIVE ASSESSMENT

Formative assessment includes a variety of procedures such as observation, feedback, and journaling. However, there are some general principles that constitute effective formative assessment. Key requirements for successful formative assessment include the use of quality assessment tools and the subsequent use of the information

derived from these assessments to improve instruction. The defining characteristic of formative assessment is its interactive or cyclical nature (Sadler, 1988). At the classroom level, for example, teachers collect information about a student's learning, make corresponding adjustments in their instruction, and continue to collect information. Formative assessment can result in significant learning gains but only when the assessment results are used to inform the instructional and learning process (Black & William, 1998). This condition requires the collection, analysis of, and response to information about student progress.

The most common procedures of formative assessment include the following.

Feedback. A teacher provides oral or written feedback to student discussion or work. For example, a teacher responds orally to a question asked in class; provides a written comment in a response or reflective journal; or provides feedback on student work.

Curriculum-based measurement (CBM). This set of standardized measures is used to determine student progress and performance (Deno, 2001). An example is the use of oral reading fluency (the number of words a student can read correctly during a timed reading of a passage) as an indicator of a student's overall reading ability (Fuchs et al., 2001).

Self-assessment. Students reflect on and monitor their progress. This activity may be performed in conjunction with a CBM, in relation to predetermined academic and behavioral goals, or with learning contracts.

Observation. A teacher observes and records a student's level of engagement, academic and/or affective behavior; develops a plan of action to support that student; implements the plan; and continues to record observations to determine its effectiveness.

Portfolios. A growth portfolio can be used to create a record of student growth in a number of areas. For example, a teacher may use writing portfolios to collect evidence of a student's progress in developing writing skills.

PROCEDURES USED IN SUMMATIVE ASSESSMENT

Summative assessment also employs a variety of tools and methods for obtaining information about what has been learned. In this way, summative assessment provides information at the student, classroom, and school levels. Defining characteristics of effective summative assessment

include a clear alignment between assessment, curriculum, and instruction, as well as the use of assessments that are both valid and reliable. When objectives are clearly specified and connected to instruction, summative assessment provides information about a student's achievement of specific learning objectives.

Summative assessments (or more accurately, large-scale, standardized assessments) are frequently criticized for a variety of reasons: 1) they provide information too late about a student's performance (Popham, 1999); 2) they are disconnected from actual classroom practice (Shepard, 2001); 3) they suffer from "construct underrepresentation" (Messick, 1989), meaning that one assessment typically cannot represent the full content area, so only those areas that are easily measured will be assessed, and hence, taught; and 4) they have a lack of "consequential validity" (Messick, 1989), meaning that the test results are used in an inappropriate way. This last concern is related to state accountability systems because high stakes, such as student retention or teacher performance pay, are attached to performance on state assessment systems, yet most of these assessments have not been designed for the broad and numerous purposes they serve (Baker & Linn, 2004). Nevertheless, summative assessments can provide critical information about students' overall learning as well as an indication of the quality of classroom instruction, especially when they are accompanied by other sources of information and are used to inform practice rather than to reward or sanction. Examples of summative assessment include the following.

End of unit tests or projects. When assessments reflect the stated learning objectives, a well-designed end of unit test provides teachers with information about individual students (identifying any student who failed to meet objectives), as well as provides an overall indication of classroom instruction.

Course grades. If end of course grades are based on specified criteria, course grades provide information on how well a student has met the overall expectations for a particular course.

Standardized assessments. Tests that accurately reflect state performance and content standards provide an indication of how many students are achieving to established grade-level expectations.

Portfolios. When used as part of an evaluation of student learning, portfolios provide evidence to support attainment of stated learning objectives.

Although formative and summative assessments serve different purposes, they should be used ultimately within an integrated system of assessment, curriculum, and instruction. To be effective in informing the learning process, assessments must be directly integrated with theories

about the content, instruction, and the learning process (Herman et al., 2006) and must be valid and reliable for the purposes for which they are used. Summative assessments should be created prior to instruction to capture and identify both the content and process of learning that represent the desired outcomes. In this way, summative assessment can serve as a guide for directing the curriculum and instruction. Performance on summative assessments must serve as a valid inference of instructional quality. For example, teacher grades generally have strong validity when compared to student performance on other academic measures (Hoge & Colardarci, 1989).

Formative assessments are more informal in nature but must also serve as valid indicators of student performance if they are to be useful in informing the teaching process. Curriculum-based measurement represents a standardized process of formative assessment that relies on the use of valid measures of student progress in a given academic area. Additionally, a strong evidence base supports the use of interactive feedback (Black & William, 1998) to increase student achievement.

HOW OUTCOMES INFORM INSTRUCTION AND EDUCATIONAL PRACTICES

A consistent feature of the research findings on formative assessment is that attention to the interactive nature of formative assessment can lead to significant learning gains (Black & William, 1998; Herman et al., 2006). Reviews of research on formative assessment processes support the use of questioning, observation, and self-assessment. Similarly, research has demonstrated positive effects on student achievement with the use of CBM (Stecker et al., 2005). Frequent monitoring of student progress to a determined goal and performance level results in higher achievement for students, particularly when teachers use the data collected to inform their instructional practices (Stecker et al., 2005).

Formative assessment can be most directly used at the individual student level because it measures how a particular student is progressing in the instructional program and identifies where support may be needed. The focus on individual students provides immediate feedback on their progress within the curriculum. Formative assessment may also be evaluated at the classroom level to inform teaching practices because it reveals how many students may be experiencing difficulty. If several students are having difficulty, then perhaps a more general change in instruction is needed. CBM in particular serves in these dual roles, but other types of formative assessment such as portfolios and journals can be used in a similar way.

Summative assessment informs instructional practices in a different yet equally important way as formative assessment.

Critics of large-scale assessments argue that they adversely affect the classroom and remain disconnected from instruction (Shepard, 2001) to the extent that they are not useful in the instructional process. However, summative assessment can serve both as a guide to teaching methods and to improving curriculum to better match the interests and needs of the students. A primary use of assessment data is in planning curricula. For example, if a school's performance on a state assessment indicates high percentages of students who do not meet standards in writing, then the school could collect more information on its writing curricula, student writing performance (through portfolios or other classroom work), and professional development needs for its teachers. After collecting such information, the school may then review and adopt new writing curricula as well as provide professional development to its teachers in order to support stronger student achievement in writing. Ongoing evaluation of the writing program would be conducted through the use of formative and summative assessment. In this manner, when summative and formative assessments are aligned, they can inform the instructional process and support both the daily instructional practices of teachers as well as the longer-term planning of curricula and instruction.

Assessment entails a collection of procedures that inform the learning process. Formative and summative assessment entail integrated components of the larger process of assessment, instruction, and curriculum. However, an ample research base suggests that practitioners have difficulty implementing formative assessments (Marsh, 2007) and responding to data collected through summative assessments (Popham, 1999). When formative assessments are used in conjunction with summative assessment, the potential exists to improve outcomes for all students (Stiggins, 2002), both those meeting a minimum performance standard and all other students across the spectrum. Assessments can only serve this purpose, however, when teachers are supported to implement and respond to the procedures through corresponding adjustments in their instruction (Herman et al., 2006; Marsh, 2007).

G

GAGE, NATHANIEL LEES 1917–

Nathaniel Lees Gage is one of the most highly regarded educational psychologists of his time, the editor of the first *Handbook of Research on Teaching* (1963a), the champion of the scientifically based assertion in the field of education (Gage, 1978; 1985), and the “proud papa” of some of the most productive educational psychologists working since the late twentieth century in the United States and Canada.

N. L. Gage was born in New Jersey in 1917, one of two sons of Polish emigrants determined to raise their children as intellectuals. After departing the east coast as a junior in college, Gage completed his bachelors degree at the University of Minnesota, where he majored in psychology and worked in the lab of B. F. Skinner (1904–1990). Upon graduating college in 1938, Gage enrolled in a then new educational psychology doctoral program at Purdue University to work with a professor named H. H. Remmers. Gage and Remmers collaborated for many years until Gage completed his doctorate in 1947.

The career of Gage since that time spans his tenure as assistant and then associate professor at the University of Illinois beginning in 1948, through his presidency of the educational psychology division (Division 15) of the American Psychological Association (APA) in 1960, and his presidency of the American Educational Research Association (AERA) in 1962, to his long and acclaimed university teaching as the Margaret Jacks Professor of Education at Stanford University, where he retired Emeritus in 1987 at age 70. Throughout his career Gage was known to his students as a warm, engaging man, always

present with a smile and a twinkle in his eye. Many of those students simply called their esteemed professor “Nate.”

Three contributions for which Gage is perhaps most widely known are his highly commended editing of the first *Handbook of Research on Teaching*, his ability to produce some of the most prominent professors in immediately succeeding generations of educational psychologists, and his strong writing on the scientific basis of research on teaching. Each of these achievements deserves some elaboration.

The *Handbook*, as it came to be called by students who dog-eared its pages between its publication date of 1963 and the appearance of the second *Handbook* a decade later, is a masterful collection of chapters written by established scholars in education that reshaped the landscape of educational research. The *Handbook* organized a heretofore scattered field both substantively and methodologically, with Gage’s (1963b) own chapter on “Paradigms for Research on Teaching” as a guide. The *Handbook* provided cogent criticism of extant research methods in the field of education and models for addressing key issues in sampling, design, measurement, and data analysis; some chapters of the volume, such as that of Campbell and Stanley on experimental design, were developed into books. It was Gage who secured funding for the *Handbook*, selected its topics and authors, and meticulously edited each and every page. Widespread attention to the *Handbook* gave new promise to diligent empirical work in education, inspiring a generation of scholars to take up the gauntlet in their own careers.

Gage's own chapter in the *Handbook*, which was translated into German, encouraged him to focus his own research efforts into the 1970s on classroom research on teaching. Working at the Stanford Center for Research and Development in Teaching, which he helped to found in 1965, Gage was able to secure federal funding to build and sustain a research team that labored over the next two decades to move from correlational to experimental methods in assessing the validity of process-product models connecting teacher behavior to student learning outcomes in a variety of field-based samples (e.g., Gage, 1967). Gage had a knack for finding promising graduate students to direct and form his teams. Directors were Christopher Clark and John Crawford, who with their teams and Gage produced papers published in archived journals demonstrating the important influence of particular combinations and sequences of instructional behavior in influencing student classroom learning. Some of the students on those teams who have gone on to become APA Division 15 and AERA presidents in their own right, deans of schools of education, and endowed chairs at major research universities in the United States and Canada, include Ronald Marx, Penelope Peterson, Dale Schunk, and Philip Winne.

Other projects Gage completed with prominent educational psychologists include a textbook, co-authored with David Berliner, for teaching educational psychology that ran to six editions (Gage & Berliner, 1998), and book chapters and reports with Theodore Coladarci, Torsten Husen, Barak Rosenshine, and Albert Yee. Gage's closest professional colleague at Stanford was Richard Snow. All of the students mentioned had early successes stemming, in part, from Gage's steady influence Gage, and many have contributed chapters to one or more of the subsequent three handbooks of research on teaching.

The books that Gage wrote arguing cogently for evidence-based assertions in the field of education are often cited as background for a resurgence of this view since 2002. The first book (Gage, 1978), written as a series of sponsored lectures at Teachers College, Columbia University, has been on the basic reading list of doctoral courses in research on teaching since its publication.

Following his retirement, Gage continued to be active in conceptualizing and writing, working on a theoretical extension of his ideas on the "hard gains" still to be made in the field of educational psychology. Gage sought a theory of research on teaching that had solid empirical evidence as a basis, a theory that explained in technical terms how teachers can make a real difference in the lives of their students. In 1985 Gage wrote *Hard Gains in the Soft Sciences*, and since then he has penned articles in several other refereed journals confronting important issues that continue for research on teaching, always championing the warranted assertion,

always defending the usefulness of research to the practicing field of education. This is one teacher who *did* make a difference in the lives of his students; perhaps that explains Gage's lasting commitment to a theory of teacher effectiveness.

GAGNÉ, ROBERT MILLS 1916–2002

Robert Mills Gagné, an education psychologist best known for his book *The Conditions of Learning*, was born in 1916. He received his BA from Yale University in 1937 and went on to earn a PhD (1940) in experimental psychology from Brown University. During a career of 50 years, Gagné held both academic and research and development positions in military training and in human performance. In 1940 he held a position at Connecticut College for Women. He taught at Princeton University from 1958 to 1962 and from 1966 to 1969 at the University of California, Berkeley. Next he taught at Florida State University from 1969 to 1985. During a hiatus from teaching from 1962 to 1966, Gagné served as director of research at the American Institute for Research in Pittsburgh, Pennsylvania. He died in 2002.

As a graduate student in 1964 it was the privilege of this writer to read *The Conditions of Learning* in manuscript. This book was first published in 1965 and appeared in three additional editions (1970, 1977, and 1985). It became perhaps the most important work in instructional design, laying the foundation for a theory- and research-based approach to the design of instructional materials. Gagné's unique approach was founded first in behavioral psychology and later in cognitive processing. The prescriptions Gagné advocated

were all based on theory supported by research in the psychology of learning. This book and the friendship this writer developed with Gagné throughout the remainder of his life had a profound influence on this writer's career in instructional technology.

Many would acknowledge Robert M. Gagné as the father of instructional design, in which area he made three major contributions. First, regarding cumulative learning theory and learning hierarchies, Gagné advocated starting with the final task to be acquired and asking, "What must the learner do to accomplish this task given only directions?" This hierarchical analysis is repeated for each subsequent task until all the prerequisite skills for a given task have been identified. The resulting learning hierarchy provides a map for the subsequent instruction.

Second, Gagné identified five varieties of learning and the internal (cognitive) and external (instructional design) conditions necessary to promote effective and efficient acquisition of each of these different kinds of knowledge and skill. The categories Gagné identified were modified with each edition of *The Conditions of Learning*. The last list included the following intellectual skills: discriminations, concrete concepts, defined concepts, and rules; cognitive strategies; verbal information; problem solving; motor skills; and attitudes. When these conditions of learning are implemented in instructional materials, research shows that the resulting learning is more efficient and effective. Most instructional designers are also familiar with Gagné's third contribution, his nine events of instruction, and have used them as a guide to designing effective lessons. These events are: gaining attention, informing the learner of the objective, stimulating the recall of prior learning, presenting the stimulus, providing learner guidance, eliciting the performance, giving informative feedback, assessing performance, and enhancing retention and transfer.

Jointly Gagné and this writer proposed the notion of integrative goals, bringing together into an integrated whole the different varieties of learning. This author's own work continued into the early 2000s to build on Gagné's contributions with the identification of first principles of instruction, including problem-centered instructional design. An important collection of Gagné's papers and a brief summary of his life can be found in *The Legacy of Robert M. Gagné* (2000), edited by Rita Richey.

M. David Merrill

GARDNER, HOWARD 1943–

Howard Gardner, a professor at the Harvard Graduate School of Education, is a developmental psychologist best known for his theory of multiple intelligences. The author of more than twenty books and several hundred journal articles, he has also conducted research in fields ranging from arts education to creativity to socially responsible work.

Born in 1943, Gardner grew up in Scranton, Pennsylvania, the son of German-Jewish immigrants who fled Germany prior to World War II. Gardner was an excellent student as well as a talented pianist. He gave up formal study of the piano as an adolescent in order to focus on academics, but his interest in music and the arts has remained an important part of his life and has also influenced his academic pursuits. Gardner graduated from Harvard College in 1965 where he studied with the renowned Erik Erikson, and then he earned his doctorate at Harvard in developmental psychology, during which time he worked with Roger Brown, Jerome Bruner, and Nelson Goodman, among others. Gardner is one of the founding members and remains a senior director of Harvard's Project Zero, a research group established in 1967 and dedicated to the study of cognition, creativity, and the arts. From 1971 to 1991 he also carried out a research program in neuropsychology at the Boston Veterans' Administration Medical Center. In 1986, he was named the John H. and Elizabeth A. Hobbs

Howard Gardner JAY GARDNER ©2003.

Professor of Cognition and Education at the Harvard Graduate School of Education.

Gardner's earliest books such as *The Arts and Human Development* (1973) and *The Shattered Mind* (1975) draw on his empirical investigations in the fields of developmental psychology and neuroscience. He is best known for his 1983 publication *Frames of Mind: The Theory of Multiple Intelligences*. In this work, Gardner laid out his theory that human intelligence is better understood as a multiple rather than unitary construct. Gardner originally conceived of seven distinct intelligences: linguistic, logical-mathematical, bodily-kinesthetic, spatial, musical, interpersonal, and intrapersonal. In the 1990s he added an eighth intelligence: naturalist intelligence. Gardner's work on multiple intelligences has been controversial in the psychology world, but has been enthusiastically embraced by many in the educational community. Multiple intelligences schools, which shape their mission and curricula around the eight intelligences, have sprung up around the world. Hundreds of books have been written in numerous languages about incorporating multiple

intelligences theory into the curriculum. In 2005, Danfoss Universe, a multiple intelligences science and adventure park, opened in Denmark. For his work, Gardner received a MacArthur Genius Prize in 1981 and became the first American to win the University of Louisville's Grawemeyer Award in Education in 1990. He has also received honorary degrees from more than twenty universities in the United States, Ireland, Italy, Israel, Chile, and Korea.

In 1995 with colleagues Mihaly Csikszentmihalyi and William Damon, Gardner began the Good Work Project, which seeks to identify individuals and institutions that carry out work that is excellent in equality, socially responsible, and meaningful to its practitioners, as well as the forces that support and inhibit such efforts. The project has investigated good work in the fields of journalism, medicine, theater, business, law, education, philanthropy, and genetics; its findings have been described in numerous books and papers (see goodworkproject.org). Books co-authored by Gardner that have come out of the Good Work Project include *Good Work: When Excellence and Ethics Meet* (2001), *Making Good: How Young People Cope with Moral Dilemmas at Work* (2004), and *Responsibility at Work* (2007). In 2005 Gardner and several other researchers developed a Good Work toolkit that includes activities and moral dilemmas designed to encourage high school and university students to think critically about what constitutes high quality and meaningful work. Numerous secondary schools and universities have used the toolkit in a variety of ways to encourage reflection about good work.

In 2000 Gardner, Kurt Fischer, and others colleagues at the Harvard Graduate School of Education developed a master's program in Mind, Brain and Education, thought to be the first such program in the world. Since then, similar programs have been founded both in the United States and abroad. Gardner has also continued to write about the mind/brain. In 2004 he published *Changing Minds*, a work about the seven levers of mind-change. In 2007 he published *Five Minds for the Future*, a policy book about the five types of minds Gardner regards as essential for success in the 21st century. As of 2007 he continues to write and speak about the theory of multiple intelligences as well.

GENDER BIAS IN TEACHING

A common response from teachers when asked about gender inequity in classrooms is that they treat all their students the same. There are two problems with this statement. First, students are diverse and have different learning issues, thus treating all students in the same way means that some students will have a better learning experience than their peers. Second, teachers may be ignoring their unconscious gender biases towards their students, their schools and themselves. If ignored, these gender biases, which may have developed from cultural norms, may lead to bias in the classroom.

Gender bias occurs when people make assumptions regarding behaviors, abilities or preferences of others based upon their gender. Because there are strong gender role stereotypes for masculinity and femininity, students who do not match them can encounter problems with teachers and with their peers. For example, the expectation is that boys naturally exhibit boisterous, unruly behavior, are academically able, rational, and socially uncommunicative, whereas girls are quiet, polite, and studious. Girls are also expected to possess better social skills than boys and to excel at reading and the language arts. So girls who present discipline problems for teachers, or quiet, studious boys, may encounter a lack of understanding from peers and teachers. Within the classroom, these biases unfold in students' practices and teachers' acceptance of certain behaviors from one student or another based upon the students' gender. Also, bias due to a person's gender is not mutually exclusive of other social categories such as race, ethnicity, class, religion, and language. For example, some teachers may

perceive African American or other Black girls as loud and uncontrollable because the girls do not exhibit the feminine behaviors associated with White women, such as quiet, self-effacing and malleable.

Gender bias can occur within subject areas and school activities. For example, in subjects such as mathematics and the sciences, there are different participation patterns for girls and boys. Gender bias promulgates a myth that boys are naturally better at mathematics and science than girls. The implications are that if girls succeed in these subjects it is due to their hard work, not their intelligence, whereas boys' success is credited to their natural talent. There are some signs that gender bias in schools may be decreasing in some areas. The percentage of girls participating in science has increased and achieved parity with boys in biology, chemistry and algebra. However, subjects that are prerequisites for college majors such as engineering or physics remain dominated by men. Only 25% of high school students enrolled in physics are female. Moreover, there has been little increase in the percentage of women in engineering programs.

Males are also more likely than females to be in remedial programs, and students' race also impacts these patterns. For example, African American males are more likely than White or female peers to enroll in remedial reading and mathematics courses. And non-White students have a higher representation in vocational and non-college preparatory courses than their White peers. Teachers are critical components in challenging gender bias in schooling, but they also can be major contributors to it as well, through their pedagogical practices, curriculum choices, and assessment strategies.

GENDER BIAS IN TEACHERS

Teachers' unconscious gender biases can produce stereotypical expectations for students' success and participation in the classroom. Teachers view male students' domination of the classroom and their time as typical masculine behavior. However, these biases have consequences for the students and the classroom climate. More than two decades ago, researchers identified and named groups of students who dominated the teacher's time and the classroom resources as "target students" (Tobin & Gallagher, 1987). Target students were typically white and male. They answered most of the teacher's questions and also asked most of the questions. This behavior pattern was particularly insidious in mathematics and science classrooms because teachers did not expect girls to have competent knowledge in these subject areas. Classroom observations documented that target students typically called out answers to the teacher's questions, thus denying other students the opportunity to engage in dialogue

with the teacher or get to grips with the subject matter. Furthermore, because boys are perceived as having natural talent in science, teachers asked boys harder and more complicated questions than girls. If girls attempted to answer more difficult questions than boys and faltered, teachers often repeated the question and asked that another student, typically a boy, provide the answer. However, if a boy failed to answer correctly, teachers reframed the question or broke it into a series of simpler questions that could help the student find the answer. Teachers' unconscious stereotyped gender bias that boys are smarter than girls, especially in mathematics and the sciences, meant they were willing to work with boys to reach the answer because they perceived boys were capable of achieving that goal but girls were not. Conversely, teachers of subjects perceived as feminine will spend more time engaged with girls.

Teachers' gendered perceptions of students' ability is also reflected in the type of praise and expectations they have of their students. Teachers often give girls less meaningful and less critical praise than boys. Boys' work is described as unique or brilliant, while girls' work is often undervalued, critically ignored, and praised for its appearance. This aspect of teachers' behavior is particularly detrimental to girls because it means they do not receive feedback on their work that could help them develop deeper understandings of concepts (Liu, 2006).

Teachers also use target students to maintain the tempo and pace of classroom instruction. For example, in a lecture or whole class discussion when a teacher is posing questions to the class, he or she may encourage target students to call out answers in order to keep the lesson moving, rather than wait for the other students to process the question and provide an answer. This short "wait time" may be detrimental to learning. More than three decades ago, researchers found that if teachers waited three to five seconds before accepting a student's answer, more students became engaged in the classroom and also improved their understanding of the content. Moreover, the longer wait time meant that teachers began to ask more cognitively challenging questions. However, the existence of target students in classes who often call out answers without direction from teachers meant that fewer students, especially girls, engaged in the lessons. In the absence of proactive teacher intervention, these patterns in which males dominate classroom interactions also occur in mixed-gender, small groups.

Target students dominate classroom interactions and exchanges at all education levels. In the early 2000s, researchers identified these same patterns of engagement in a professional development program for science teachers. When alerted to the invasive behaviors of the male teachers in the cohort, faculty began using overt breach-

ing strategies to stop the target students calling out answers, dominating the human and materials resources of the classroom, and showing disrespect to their peers (Martin, Milne & Scantlebury, 2006).

Teachers' gender bias towards students can also extend to their response to students who challenge their authority. Such risk-taking behavior in boys is expected and at times praised, but assertiveness in girls is viewed negatively and labeled unfeminine. Similarly, boys who do not exhibit stereotypic masculine behaviors may be ridiculed (Renold, 2006).

Teachers use gender expectations as a means of maintaining classroom control. For example, teachers will seat undisciplined boys next to girls as a classroom management strategy. Further, teachers use the gendered expectation that girls' nurturing characteristics will lead them to place others' needs before their own. In other words, teachers often ask girls to assume mothering roles towards students who have fallen behind with learning because of inattentiveness, absenteeism through truancy, or in-school disciplinary procedures, and often those students are male.

PEDAGOGICAL CHOICES AND ASSESSMENT PRACTICES

Girls and boys have different educative experiences in classrooms. Target students can dominate lecture-style classes, and most students prefer to learn in groups, using hands-on activities. Group work can engage more students, but teachers must monitor the interactions between students in those groups to ensure all students are participating and that one student is not dominating the group. Students, especially girls, dislike lectures, worksheets and 'busy' work assignments, preferring to study subjects and topics that they perceive as relevant to their lives. However, girls are often relegated to passive roles in the class and in performance-based assessments. Whereas boys use equipment and complete the tasks, girls read the instructions and record results (Scantlebury & Baker, 2007).

Although publishers have reduced gender bias in textbooks, girls are often depicted in passive roles with boys as active participants. Teachers can help to counteract this bias by reviewing classroom texts from a gender perspective and analyzing the hidden curriculum promulgated by these books. Moreover, they can also counteract this message about girls' passivity by highlighting girls' and women's achievements. They can also asking students to critically examine texts for these subtle gender stereotypic messages.

Teachers often use girls as a civilizing influence on male students. Disruptive boys are reassigned to sit near or with girls. Yet little thought is given to the impact that

this strategy has on girls' learning or students' attitudes towards the classroom environment. Rather than expecting boys to exhibit self-control and regulation, when teachers use this practice it reinforces the stereotype that boys are undisciplined, whereas girls are cooperative and orderly. It also implies that boys need looking after, and the girls are cast in a maternal role to do just that.

Gender bias can also occur with the style and type of assessments teachers use. For example, teachers often use multiple-choice questions as the primary format in assessments. Girls are not encouraged to explore risk-taking behaviors and often do not venture a guess on a multiple choice test, even if they are not penalized for incorrect answers. Girls are therefore less likely to complete multiple-choice exams than their male peers because if boys are uncertain or do not know, they will guess an answer. However, when high-stakes tests use a variety of question types, for example, short answer, problem solving, and multiple choice, often gender differences in student achievement disappear (Kahle, 2004).

EFFECTS OF GENDER BIAS

Gender bias can impact students' attitudes towards learning and their engagement with the subject. If affected by gender bias, girls will tend to believe that any success they have is due to hard work rather than any innate talent or intelligence. Boys may be encouraged to believe that success in science and mathematics should come easily to them because of their gender. Some males report dropping out of college science and mathematics programs because they no longer perceive these subjects as easy. Overall, teachers have lower expectations for girls' academic success compared to boys, and their attitudes are shown through the type and quality of the student-teacher interaction. The type and quality of critique teachers give their students can also have an impact. Teachers' comments on girls' work focuses on its appearance but with boys' work teachers focus on the content. Girls often do not receive substantive comments or criticism from teachers from which they could improve their ability to learn. During the many hours spent in classrooms, girls receive less time and attention from teachers than their male peers. Teachers usually ask girls easier questions than they ask boys. Typically, girls receive fewer opportunities to engage in classroom discourse, use equipment and assert their knowledge in classrooms.

REDUCING GENDER BIAS

Gender bias in education is a series of microinequities whose impact is cumulative and often ignored. Girls are rewarded and praised for compliant behavior. Teachers do not challenge girls with questions and rarely offer criticisms of their work. Teachers can reduce and challenge gender bias through an examination of their peda-

gogical practices and by posing simple questions about their practices. For example, which students do they frequently interact with? Are target students evident in their classroom? If so, how does the teacher deal with those students? What questioning techniques does the teacher use to engage students? Does the teacher ask complicated questions to girls as well as boys? Does the teacher use a variety of pedagogical and assessment practices? Which students are engaged with the curriculum?

Another way of reducing gender bias would be for teachers to videotape their classes and review their interactions with the students. Or they could invite a colleague to watch their teaching and record which students are being asked questions and what type of questions. However, teachers must also prepare for the consequences of changing their practices. Girls are conditioned to receiving less of the teacher's attention, and they do not usually cause discipline problems if they are not receiving their fair share, but boys can react negatively to losing the teacher's attention, causing disruption to lessons and becoming discipline problems. Moreover, research has also shown that boys avoid written work and often have poor communication skills when asked to work in single-sex groups.

However, the gains in reducing gender bias in education may disappear with the requirements of high-stakes testing required by No Child Left Behind (NCLB). NCLB requires that states report academic achievement data in most social categories, except gender (Kahle, 2004). This may result in less attention being placed on gender bias and less data that might reveal it. Continued monitoring of gender bias is necessary to minimize its impact on students' opportunities for learning and achievement.

Kathryn Scantlebury

GENDER IDENTITY

Gender identity refers to an individual's identification with a particular gender category; the term encompasses the sense of belonging, attitudes, and values associated with that gender. It can be considered one part of an individual's greater identity or the enduring sense of who one is and what one wants to do. Gender identity is different from sex, which is determined by physiological characteristics of a male or female; it is also different than gender, which is a social determination of what it means to be a man or a woman. In other words, an individual may be biologically female and viewed by society as a woman but may not necessarily identify strongly with the roles, attitudes, and values that most people in society associate with being a woman.

MODELS OF GENDER IDENTITY

Much of the work on gender identity borrows heavily from research on gender roles and gender schema theory, associated with Sandra Lipsitz Bem. In Bem's theory, strong sex role identification leads to the acquisition of attitudes and behaviors in line with that role. Within this theory, individuals of either gender can take on masculine or feminine roles. Moreover, some individuals display a combination of masculine and feminine roles, while others do not identify with either set of roles. Bem would refer to the former group as androgynous and to the latter group undifferentiated.

Similarly, Janet Taylor Spence refers to differences between instrumental traits and expressive traits, which are similar in concept to Bem's masculinity and femininity, respectively. Spence argued, however, that such a unidimensional view was not enough to fully capture gender identity. She advocated instead for a multidimensional view of gender identity, with each dimension having unique developmental components and correlates. Further work on such a multidimensional conceptualization, by Susan Egan and David Perry, identified four factors based on previous gender research: knowledge of membership in a gender category, feelings of compatibility with gender, feelings of pressure to act in accordance with the gender's roles, and ingroup bias toward the gender. Knowledge of membership refers to the individual identifying of oneself as a man or a woman. Compatibility refers to the extent an individual feels like a typical

member of one's gender and even the extent to which one feels content with the gender assignment. Pressure refers to the extent to which an individual perceives parents, peers, and self as wanting the individual's self to conform to gender stereotypes. Finally, ingroup bias refers to the extent to which individuals prefer the gender with which they identify opposed to the other.

DEVELOPMENTAL CHANGES IN GENDER IDENTITY

Much of the research on the development of gender identity focuses on the development of gender constancy or sustained knowledge of one's sex. Between the ages of two and a half years and six years, children develop a sense of gender constancy. This means that by the age of six, children are able to answer the question, "are you a boy or a girl?" and realize that this answer does not change over time or with differences in appearance (e.g., a boy who wears a pink dress is not suddenly a girl).

Views on the development of additional characteristics of gender identity vary depending on whether one takes a unidimensional or multidimensional perspective on the construct. With a unidimensional view, the understanding of sex roles comes from the discovery of gender constancy, as children learn what is and is not appropriate for their gender. This view of learning and internalizing sex roles is addressed thoroughly using social cognitive theory. It is more difficult to summarize the development of specific dimensions of gender identity in the multidimensional perspective because each dimension has its own trajectory of growth and correlates.

Regardless of which perspective one takes when discussing gender identity, its development remains a salient issue among adolescents. Traditionally, during adolescence individuals begin coming to terms with their overall identities. As adolescents begin assessing who they are and what their roles in the world will be, they have questions regarding the extent to which they are aligned or not with gender-stereotypic behaviors. Just as research shows the importance of a strong general identity in positive psychosocial development, a strong gender identity is also associated with positive psychosocial outcomes. Gender identity need not be sex-stereotypical to be strong; rather, individuals with strong, positive gender identities are confident in who they are and have social support for their identity.

GROUP DIFFERENCES IN THE DEVELOPMENT OF GENDER IDENTITY

The general pattern of gender identity development may differ across groups. Most notably, several theorists have focused specifically on the development of gender identity

among women. The work of Carol Gilligan on identity development in females, while not specifically related to gender identity, has several implications in this area. Gilligan's theory states that as girls enter adolescence, they must come to terms with the silent role of women in the social world. Often, this is accompanied in adolescence by a time when girls silence their thoughts and identity. Several theorists have similarly proposed models, specifically for the development of gender identity among women, referred to as feminist or womanist identity theories. These theories focus on the importance of reconciling negative social views of women with individual attitudes and values.

In addition, several studies have concentrated on the extent that race and ethnicity moderate the development of gender identity. Much of this work focuses on African American children and adolescents and has found that negative stereotypes associated with being a Black boy or girl are a risk to positive gender identity development. Some researchers have amplified these general findings by asserting more specifically that stereotypes of the perfect boy or the perfect girl are often White; therefore, the negative outcomes among racial-minority adolescents come from a desire to oppose this standard. Positive identity development is achieved by guiding these adolescents toward more prosocial ways of opposing this standard of perfection.

Another line of research focusing on racial/ethnic variation in the development of gender identity addresses the relationship between gender identity and positive psychosocial outcomes. One such study found that several dimensions of gender identity related to positive psychosocial development for White adolescents were not related for African American adolescents. Among Hispanic students, stronger gender identity was related to negative development for females but related to positive development for males. More research in this area is needed to understand why these differences occur.

GENDER IDENTITY AS RELATED TO SCHOOL OUTCOMES

Compared to the literature on gender differences in school outcomes, research specifically related to gender identity is lacking. However, the consideration of gender identity is important for more fully understanding observed gender differences in many school-related outcomes.

One line of research relating gender identity to academic outcomes focuses on achievement motivation, and in particular on self-efficacy and stereotype threat. First relating to self-efficacy, some research shows that students with more masculine or androgynous orientations have higher levels of general and academic self-efficacy than do students with feminine or undifferentiated orientations, regardless of gender. Other studies suggest that this rela-

tionship between gender identity and self-efficacy may be more subject-specific. For example, some research has found that feminine-oriented students hold higher self-efficacy in writing.

The consideration of gender identity in relation to achievement motivation also has implications for research on stereotype threat or the decrease in achievement when faced with the possibility of confirming a negative belief about one's ingroup. Studies find that female students' mathematics performance diminished when confronted with a threatening gender-related stereotype. Together, research on self-efficacy and stereotype threats approach gender differences in performance as due to enhanced efficacy or anxiety resulting from the requirement of characteristics that are supposedly like or unlike the individual. Improving performance then becomes a matter of persuading students that they can succeed in any subject regardless of their gender.

Additional research focuses on the interaction between students' gender identities and their identities as students. According to research in this area, students view the perfect male and female students differently. The ideal female student is beautiful and does not have to work too hard at being smart; the ideal male student is loud and funny. At the same time, ideal male and female students are good at different subjects, with the ideal male student excelling in the sciences and the ideal female student excelling in the arts. Male students hold the most gendered views of good students and are less likely to report liking non-conforming students. This line of research has implications for understanding both how the social context of schools shape gender identities and how students with non-conforming gender identities perform and are accepted in school.

GENDER ROLE STEREOTYPING

Gender role stereotyping occurs when a person is expected to enact a series of norms or behaviors based upon their sex. Gender is a social construction, and other social categories such as race, ethnicity, class, religion, and language also influence that construction. In most European and North American societies, gender roles divide through male and female behavioral norms. Certain types of behaviors are categorized as masculine or feminine. However, gender as a continuum is social and relational, rather than categorical. In other words, gender only exists as a comparative quality (if people are “less masculine” than others, they are also “more feminine” than those same others, even if their biological sex is the same). Thus gender role stereotyping occurs when individuals are expected to enact certain practices or behaviors because of their gender.

Although girls’ schooling experiences vary depending upon their socioeconomic status, geographic location, ethnicity, and/or disability (AAUW, 1998), many schools, and other educational institutions, reinforce and support gender stereotyped roles. Moreover, schools operate through the interactions of groups and individuals, and how students and teachers construct gender in the classroom impacts the learning environment. Two decades after Title IX of the Elementary and Secondary Education Act legislation

banned sex discrimination in education programs and activities, public schools still exhibited bias against girls. In 2005, comments by the then-president of Harvard University Lawrence Summers suggesting that innate sex differences may contribute to fewer female faculty in the sciences resulted in national and international discussions on how cultural factors are more likely to explain women’s participation in science than biological differences between females and males.

The gender role stereotypes that schools help to reproduce include the notion that girls are caring, nurturing, quiet, helpful, considerate of others, and place others’ needs before their own. Academically able girls’ achievements are attributed to their hard work, whereas successful boys are considered naturally gifted. In contrast, underachieving male students are considered lazy, whereas underachieving girls are regarded as not capable. Boys are viewed as rational, logical, unemotional, and strong and are also expected to be outgoing, smart, and naturally academically talented. Thus in schools, gender role stereotypes attribute males’ academic success to innate intelligence and girls’ achievements to hard work. Moreover, these gender differences are explained through biological differences without any consideration of the impact of social environment on students’ learning, achievement, motivation and attitudes.

GENDER ROLE STEREOTYPES AND STUDENT TEACHER INTERACTIONS

Gender role stereotypes also influence classroom interactions between teachers and students. First, students who dominate the classroom, answering and asking most of the questions, and using the available resources, are called target students. Regardless of the schooling level, target students are typically White males. Teachers predominantly ask White male students more and harder questions than any other group of students because these students are viewed as inherently smart. If a target student fails to answer a question, teachers will often reword or reconstruct the question, breaking a difficult question into a series of simpler questions to attain the answer. If other students are unable to answer a question teachers typically move on, usually to a target student.

Overall, boys are more likely than girls to answer teachers’ questions. Often they call out answers, a risk-taking behavior expected of males, and seek the teacher’s attention. In contrast, girls are more likely to receive criticism rather than praise for such risk-taking behavior. Teachers reward girls for being compliant, quiet, and helpful, which are stereotypic feminized behaviors. These behaviors in girls are also associated with White culture. Thus African American girls, whose socialization encourages assertive behavior,

are often at odds with teachers who deem practices such as asking questions before being acknowledged, and non-compliance, as unfeminine.

INFLUENCE OF GENDER ROLE STEREOTYPES ON SCHOOL SUBJECTS

The accepted and encouraged assertive behavior in males that produces target students also enables boys to control other resources. For example, in science classes boys dominate equipment and relegate girls to roles such as data recorder, reading instructor, or cleaning up the work area. Girls' stereotyped views of science as a masculine endeavor may mean they prefer these passive roles. However, laboratory work can be an important facet of learning science and if girls are disengaged or relegated to peripheral roles they may not fully focus on the subject matter.

Recent data shows that there are equal numbers of girls and boys enrolled in high school science classes, with the exception of physics and Advanced Placement science courses (Scantlebury, 2006). Girls prefer studying subjects that they perceive as having value, being connected to people or other living things and having relevance in their lives. Often science is taught without an emphasis on how the subject connects to the "real" world. Boys are viewed as less able than girls in reading and the language arts, subjects that are stereotyped as feminine.

MOTIVATIONAL AND BEHAVIORAL CONSEQUENCES OF STEREOTYPING

The acceptance of gender-stereotyped roles as normal behaviors, with boys being rewarded for assertive behavior, uniqueness, and risk-taking, and girls for nurturing, conformity, and placing others' needs before their own, is often invisible to students and teachers. Moreover, participants in classrooms do not notice how the subtle inequities that are the outcomes of these behaviors impact students' motivations and behaviors. For example, the expectation that girls place others before themselves has consequences regarding their attitudes towards success in school. Girls' motivation for succeeding in school is often related to pleasing others, such as parents and teachers, rather than themselves. They report doing well in classes because of a personal, positive connection with their teachers. However, that personal connection is often missing in first-year, college-level classes when they become merely one student in classes of several hundred. As young college women they may struggle with their studies because there is no one person to achieve for, and they are not used to achieving for themselves.

Girls' preference for a positive, personal connection with their teachers can also influence their course selection. For example, young women may avoid advanced mathematics or science because they dislike the teacher. Another consequence of gender stereotyping for girls is learned helplessness. When girls struggle with learning material, teachers often give them the answer, promulgating a status of learned helplessness. In other words, because they are given the answers, girls learn that they are not capable of learning.

For females, placing others first is an important characteristic of a caring, nurturing person. A consequence of this practice is girls' fear of success. Girls often may not succeed in their academic achievements because to do so may be viewed as unfeminine, which may reduce their attractiveness to boys.

For males whose achievement is attributed to their natural intelligence, problems arise when this natural ability is no longer a guarantee of success. They perceive themselves as failures and often change majors instead of addressing their fear of failure by re-examining study habits and patterns.

Gender role stereotyping impacts students' perceptions of their abilities and their achievements. Similarly, research has shown that teachers' and parents' expectations of students' abilities, achievements and behaviors are influenced by gender role stereotyping. Gender role stereotyping is usually subtle, and often unrecognized or unchallenged. The assumption that girls should assume feminine traits in school such as caring for others, and quiet and unassertive behavior, can mean that they set aside their own learning needs for others. For boys, the masculine gender role stereotype suggests that they should have natural talent to achieve, and that they are expected to exhibit rationality and logic as well as loud, domineering behaviors.

Gender role stereotypes remain strong influences in society, schools and the daily life in classrooms. Yet inequities because of gender issues are often rendered invisible to students and teachers by their very pervasiveness in classrooms. A major challenge for educators is to establish classroom environments that do not favor one group of students to the detriment of another group, and recognize that gender role stereotypes remain a major influence on schools' organization, teachers' practices and students' attitudes and behaviors.

GIFTED EDUCATION

In the most recently released federal report, as of 2007, titled *National Excellence, A Case for Developing America's Talent* (O'Connell-Ross, 1993), a quiet crisis is described related to the education of gifted and talented students in the United States. The report asserts: "Despite sporadic attention over the years to the needs of bright students, most of them continue to spend time in school working well below their capabilities. The belief espoused in school reform that children from all economic and cultural backgrounds must reach their full potential has not been extended to America's most talented students. They are underchallenged and therefore underachieve" (p. 5).

DEFINING GIFTEDNESS

For many years, psychologists and psychometricians, following in the footsteps of Lewis Terman in 1916, equated giftedness with high IQ. In the early 2000s, this legacy is beginning to dissipate, but in some states, giftedness is still defined as an IQ of 130 or above, and this type of score is required for identification of gifted students. Research, however, from 1975 to 2005 supports a broadened conception of giftedness (Sternberg & Davidson, 1986; 2005). Most of these researchers define giftedness as a combination of multiple qualities; in addition to intellectual factors, such features as motivation and creativity are considered key qualities in many of these broadened conceptions of giftedness.

Bloom and his associates at the University of Chicago engaged in a study of the development of talent in children, examining the processes by which young people under 35 who reached the highest levels of accomplishment in academics, the arts, and sports developed their capabilities. Bloom and his associates found that the following factors play a role in the development of talent: the home environment, which develops the work ethic and the importance of doing one's best at all times; the encouragement of parents in a highly approved talent field; the involvement of families and teachers; and the presence of achievement and progress, which are necessary to maintain a commitment to talent over a decade of increasingly difficult learning (Bloom, 1985, pp. 508-509).

The importance of development throughout the lifespan of the individual is reinforced by most developmental and educational psychologists who study giftedness, as is the domain-specific nature of giftedness. Gifted individuals are seen as those who can excel usually in one domain, providing that the environmental factors enable this excellence to develop.

Joseph Renzulli's (1978) three-ring definition of gifted behavior is a widely recognized example of a multifaceted and expanded conceptualization of giftedness. Renzulli (1978; 1986; 2005) defines gifted behaviors as composed of three components as follows.

Gifted behavior consists of behaviors that reflect an interaction among three basic clusters of human traits above average ability, high levels of task commitment, and high levels of creativity. Individuals capable of developing gifted behavior are those possessing or capable of developing this composite set of traits and applying them to any potentially valuable area of human performance. Persons who manifest or are capable of developing an interaction among the three clusters require a wide variety of educational opportunities and services that are not ordinarily provided through regular instructional programs (Renzulli & Reis, 1997, p. 8).

The U.S. government subscribed to a multifaceted approach to giftedness as early as 1972 when the Marland Report definition was passed (Public Law 91-230, section 806) (Marland, 1972). This U.S. Department of Education definition has dominated most states' definitions of giftedness and talents. As of 2007 the federal definition, cited in *National Excellence*, the national report on the status of gifted and talented education, is as follows:

Children and youth with outstanding talent perform or show the potential for performing at remarkably high levels of accomplishment when compared with others of their age, experience, or environment. These children and youth exhibit high performance capability in intellectual, creative, and/or artistic areas, possess an unusual leadership capacity, or excel in specific academic fields. They require services or activities not ordinarily provided by the schools. Outstanding talents are present in children and youth from all cultural groups, across all economic strata, and in all areas of human endeavor. (O'Connell-Ross, 1993, p. 26)

Though many school districts adopt this or other broad definitions as their district's operational definition, most focus solely on intellectual ability when both identifying and serving students, and few provide programs for students with talents and gifts in the areas of creativity, the arts, leadership, and specific academic fields.

Common themes that emerge in any discussion of how to define giftedness include the need to identify the domain that serves as the basis of one's definition, whether individual or societal; the essential role that cognitive abilities and motivation play in giftedness; the importance of the developmental course of one's talents for whether or how they are expressed; and the inevitability of how one's abilities emerge and interact with educational, societal, and chance factors.

ASSESSMENT AND IDENTIFICATION OF GIFTEDNESS

Assessment and identification of gifted and talented students occurs using various methods and instruments that vary from state to state. Students are usually identified for gifted programs based on assessments of their abilities and achievement, and their creativity and motivation are often considered as well. In most school districts, an attempt is made to use multiple criteria for identification of students involving nationally normed standardized tests, as well as other measures of academic achievement, creativity, and motivation.

Classroom teachers usually nominate students for gifted programs, and children are usually referred on an ongoing basis. In addition to teacher nomination, many districts accept nominations from the student (self-referral), the parent, a peer, or from others, such as a psychologist, community members, principal, or a gifted students' coordinator. The following are usually used for assessment: group aptitude or achievement tests; various assessments of creativity or motivation; individually administered tests; auditions or performances; displays of work; and teacher or parent checklists or rating scales.

Identification of students for gifted and talented programs is usually completed using a comprehensive assessment of the child's abilities and potentials rather than simple IQ testing. The rationale for assessment typically centers on the need for developing an understanding of a child's relative strengths and how these relate to educational settings and matching children's strengths with appropriate educational programs.

There are usually three stages in the identification process. The first is nomination, which includes gathering student data from a variety of sources, including teacher, parent, and peer nominations; grades; portfolios; observations; review of student records; and outstanding products or performances. All students are involved in the pre-assessment pool to ensure equal access to screening and further assessment by all district children, including culturally or linguistically diverse children, children from low socioeconomic backgrounds, children with disabilities, and children for whom English is a second language.

The second stage is usually screening when the data gathered from the pre-assessment stage is examined to

Table 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

determine if additional assessment is necessary. In making decisions about additional assessment, existing test data for students is not the sole determining criterion. School personnel examine all available information about a student to determine if an evidence of possible giftedness exists for that student, and they conduct necessary additional assessment.

The third stage is final identification, when additional assessment has been completed, the data obtained throughout the stages of identification are evaluated, the identification decision is made, and student's educational needs are determined. The most important part of identification is to consider the purposes for identification and the match with the resulting program.

CHARACTERISTICS OF GIFTEDNESS

Multiple lists of characteristics of giftedness exist but the most common characteristics are summarized below using Renzulli's definition of giftedness in Table 1.

PROCEDURES TO MEET THE NEEDS OF GIFTED AND TALENTED STUDENTS

Renzulli and Reis (1997) recommend the development of a continuum of services to challenge the diverse learning

and affective needs of gifted and talented students. This continuum provides services that range from general enrichment across all grade levels, to curriculum differentiation opportunities for both enrichment and acceleration, to advanced classes and individualized research, as well as counseling and other services to meet affective needs. Two considerations exist when a district-wide continuum of services for academically and artistically gifted and talented students is developed.

The first consideration is organizational, relating to where and when students will be provided with services to meet their advanced learning needs and how and when different grade level students will be grouped together in or across different schools. For example, gifted and talented students can be grouped by instructional level in both elementary and middle schools. They can be cluster grouped in one or more content areas across classrooms and assigned to classes with teachers who have had professional development and use strategies to meet their learning needs. Separate classes can be provided for gifted students at any grade level. Interventions to attempt to reverse underachievement can be incorporated into counseling options either during or after school at the high school level. Students can have opportunities for advanced project work after school or during a time that their curriculum has been compacted. The second consideration in the development of a district-wide continuum of services relates to curriculum and learning opportunities, as decisions must be made about what will be taught and why and whether acceleration opportunities will be made available. Other questions to consider include whether the regular curriculum will be extended with enrichment or whether it will be compacted and replaced with teacher-selected advanced content and whether students will have the opportunity to pursue their personal interests using independent study.

Both of these considerations should be addressed as a continuum of services is developed. If organizational structures are the only component addressed in a district-wide continuum of services, little thought will have been extended to essential instructional and curricular decisions. For example, if students are grouped into a separate class for gifted students without any advanced or accelerated curriculum or instruction, little justifiable reason exists for that instructional grouping. If a large percentage of gifted students are underachieving and are not able to participate in advanced classes or are dropping out of school, an expansion of a district continuum of services should be considered to include more affective and counseling services.

Establishing opportunities for enrichment across the grade levels and differentiation in all classrooms are one way to begin the development of a continuum of services

that range from some level of service in the regular classroom setting to a separate school or center for gifted learners. School-based gifted programs should offer a diverse set of learning opportunities. Resource room programs enable teachers to send out students from their regular classrooms to spend time with other high potential students to enable them to work on in-depth, advanced independent study projects and group projects in their interest areas. In some districts, students have the opportunity to travel to a center one day each week to work with other identified gifted and talented students on advanced curriculum or to pursue individual interests.

Curriculum compacting and differentiation is also suggested to accommodate the learning needs of advanced students. In a national study on compacting, the use of compacting to differentiate curriculum and eliminate previously mastered work was used with hundreds of gifted and high-ability students. Compacting is one component of the Schoolwide Enrichment Model (SEM) (Renzulli, 1977; Renzulli & Reis, 1985, 1997) that is widely implemented as an enrichment program used with academically gifted and talented students. This talent development approach provides enriched learning experiences and higher learning standards for all children through three goals; developing talents in all children, providing a broad range of advanced-level enrichment experiences for all students, and follow-up advanced learning for children based on interests. This SEM focuses on enrichment for all students through engagement, in enjoyable, challenging learning experiences and enhancement of students' interests.

Renzulli Learning, a 2006 innovation to challenge gifted and talented learners in classrooms and in separate gifted programs, is an online system designed to use strength-based assessment and differentiated learning experiences for gifted and talented students. The online assessment, which takes about 30 minutes, results in a printed profile that highlights individual student strengths and is accompanied by a differentiation search engine that selects hundreds of resources that relate specifically to each student's interests, learning styles, and product styles.

VARIATIONS IN GIFTEDNESS

Unfortunately, the majority of young people participating in gifted and talented programs across the country continue to represent the majority culture, most likely because identification and selection procedures may be ineffective and inappropriate for the identification of these young people (Frasier & Passow, 1994). Limited referrals and nominations of students who are minorities or from other unrepresented groups affect their eventual placement in programs. Test bias and inappropriateness

have been mentioned as reasons for the continued reliance on traditional identification approaches.

In addition to students from economically disadvantaged populations, variations in gifted students include students from minority and cultural groups, as well as gifted students with various disabilities such as learning disabilities, visual and hearing impairments, and physical handicaps. Special programs, strategies, and identification procedures have been suggested for many of these groups; however, much progress still remains to be made to achieve equity for these underrepresented groups. Baum (1990) has identified four important approaches for handling gifted students with learning disabilities: encourage compensation strategies, encourage awareness of strengths and weaknesses, focus on developing the child's gift, and provide an environment that values individual differences.

Underachieving gifted learners, especially young people with high ability, whose performance fall noticeably short of potential, present the most bewildering and perhaps the most frustrating of all challenges to teachers and parents. One cause of underachievement in gifted or high potential students is the inappropriate curriculum and content which some of them encounter on a daily basis. The hundreds of hours spent each month in classrooms in which students rarely encounter new or challenging curriculum, the boredom of being assigned routine tasks mastered much earlier, the low levels of discussion, and the mismatch of content to students' ability lead to frustration on the parts of many of the brightest students. Reis and McCoach (2000) identified specific characteristics of gifted underachievers and recommended numerous strategies that can be used to reverse underachievement of gifted and talented students. This research may provide helpful insights for educators regarding the performance of some of their underachieving gifted students.

Joseph S. Renzulli

GILLIGAN, CAROL 1936-

Carol Gilligan, the author of *In a Different Voice*, is noted for her work in moral reasoning, gender differences, and feminine psychology. She was born in New York City in 1936, the daughter of William Friedman, a successful lawyer, and Mabel Caminez Friedman, a humanitarian. After attending the prestigious Walden School throughout grade school and high school, she studied literature at Swarthmore and graduated *magna cum laude*. She went on to Radcliff University to earn a master's degree in clinical psychology. At age 28 she earned her PhD in social psychology from Harvard with a dissertation entitled "Responses to Temptation in Analysis of Motives."

NOTABLE COLLABORATORS

Gilligan taught as an adjunct professor at the University of Chicago while her husband finished medical school. Years later, she returned to Harvard to work with Erik Erikson. She appreciated Erikson's concern that social scientists should contribute to the social issues of the day. However, she was frustrated that he, like so many other researchers of the day, felt that the feminine perspective had to be ignored because of the complications of mixed gender studies. In working with Lawrence Kohlberg, Gilligan recognized the seriousness of ignoring the feminine perspective. She noted

Carol Gilligan © JERRY BAUER.

that although Kohlberg's research on moral development and his stage theory of moral development, justice, and rights was impressive, the conclusions could only be applied to the population of privileged boys and men that Kohlberg's sample represented. After establishing her theory of gender differences in moral reasoning, Gilligan collaborated with Lyn Mikel Brown in developing the Harvard Project on Women's Psychology and Girls' Development and in writing the book *Meeting at the Crossroads: Women's Psychology and Girls' Development*. Brown has since become recognized as an expert on feminine psychology, particularly aggression in girls.

MAJOR CONTRIBUTIONS TO THE FIELD OF EDUCATIONAL PSYCHOLOGY

Gilligan has made two major contributions to the field of educational psychology. First is her discovery of a moral reasoning based on the ethics of care, which complements Kohlberg's morality based on the ethics of justice. Her second contribution is identifying the self-silencing of a young person's authentic voice in surrender to the expectations of society.

The recognition of a morality of care and responsibility grew out of Gilligan's work with Kohlberg. Gilligan recognized that the participants in Kohlberg's norming groups were all privileged males. This meant that any viewpoints of female participants would be compared to a collective male perspective. Gilligan noticed that when a woman, in analyzing moral dilemmas, voiced a judgment based on caring for others, her response was rated lower than a man's response based on justice. Gilligan noticed a pattern in the women's responses that was divergent from the pattern of male responses. The males in the study were focused on justice, an adherence to law emphasizing the rights of individuals. The females in the study were focused on compassion, an awareness of relationships emphasizing a responsibility toward others. Although later researchers have not found the gender differences in moral reasoning that Gilligan did, the concept of an *ethic of care* is well accepted and found in moral reasoning regardless of gender.

Gilligan discovered and validated over many years that girls tend to lose their authentic voice, the true expression of their ideals, during puberty. At age 11, a girl will tell her point of view no matter how controversial, but by age 15, she has learned to suppress it. Gilligan attributes this tendency to the young woman's confrontation with the "patriarchy," the male-dominant society. In studies with boys, Gilligan has found that boys also suppress their authentic voice but at a younger age.

MAJOR IMPACT

The major impact of Gilligan's work on psychological research is the inclusion of women as participants in studies generalized to a mixed-gender population. This has led to increased interest in feminine psychology and the inclusion of gender differences as an important part of all psychological studies. Gilligan's work has brought about a revolution in psychological research so complete that it is hard to remember a time when studies with only males as the participants were used to generalize to women's situations.

GOAL ORIENTATION THEORY

Goal orientation theory is a social-cognitive theory of achievement motivation. Goal theory originated early in the 20th century but became a particularly important theoretical framework in the study of academic motivation after 1985. Whereas other motivational theories (e.g., attribution theory) examine students' beliefs about their successes and failures, goal orientation theory examines the reasons why students engage in their academic work. Although goal orientation theory is predominantly studied in the domain of education, it also has been used in studies in the domains of sports psychology, health psychology, and social psychology.

TERMINOLOGY

In order to understand the basic properties of goal orientation theory, it is important to understand how goals are conceptualized in the research literature (Pintrich, 2000). First, in this framework, goals fall in two major classes. These classes have been referred to by various names in the literature, but for the sake of simplicity, two terms are used in this entry. The first type is called a mastery goal. Students hold mastery goals (also referred to as being mastery-oriented) when their goal is to truly understand or master the task at hand; students who are mastery-oriented are interested in self-improvement and tend to compare their current level of achievement to their own prior achievement. In contrast, the second type is called a performance goal. Students hold performance goals (also referred to as being performance-oriented) when their goal is to demonstrate their ability compared to others. Students who are performance-oriented are

interested in competition, demonstrating their competence, and outperforming others; they tend to use other students as points of comparison, rather than themselves.

Second, mastery and performance goals are each divided into approach and avoid goals. In terms of mastery goals, mastery-approach oriented students are interested in truly mastering an academic task; in contrast, mastery-avoid oriented students are interested in avoiding misunderstanding the task. In terms of performance goals, performance-approach oriented students are interested in demonstrating that they are more competent than other students (i.e., have more ability than others); in contrast, performance-avoid oriented students are interested in avoiding appearing incompetent or stupid. Below are examples for each type of goal orientation:

Mastery approach: Jennifer's goal in French class is to become fluent in the language because she is interested in the language and wants to be able to converse with others and read French literature.

Mastery avoid: Jason's goal in French class is to avoid misunderstanding the grammatical lessons presented by his teacher.

Performance approach: Haley's goal in French class is to demonstrate to her teacher and to other students that she is better at speaking French than many of her classmates.

Performance avoid: T.J.'s goal in French class is to avoid appearing incompetent at speaking or reading French.

It is important to note that students can hold multiple goals simultaneously; thus it is possible for a student to be both mastery-approach oriented and performance-approach oriented; such a student truly wants to learn and master the material but is also concerned with appearing more competent than others.

In addition, some researcher have operationalized performance goals somewhat differently and referred to them as "extrinsic goals" (Anderman & Johnston, 1998; Pintrich & de Groot, 1990). When students hold an extrinsic goal, their reasons for engaging in academic tasks are to either earn a certain reward (e.g., a good grade) or to avoid a punishment.

Third, students' goals can be conceptualized at differing organizational levels. Personal goals refer to students' individual, personally held goals; the types of mastery and performance goals described above are examples of personal goals. In contrast, classroom goal structures refer to students' beliefs about the goals that are emphasized by their teachers in their classrooms. Most researchers distinguish between a classroom mastery goal structure and a classroom performance classroom goal structure; however,

most do not make the approach/avoid distinction with classroom goal structures. When students perceive a classroom mastery goal structure, they believe that instruction in the class is characterized by emphases on improvement, learning new material to a level of mastery, and self-comparisons; when students perceive a performance goal structure, they believe that the class is characterized by competition, an emphasis on grades and relative ability, and outperforming others.

Some researchers also discuss school-level goal structures. A school can be perceived by students as being mastery oriented (i.e., the culture of the school focuses on learning, improvement, and task mastery) or as being performance-oriented (i.e., the culture of the school focuses on grades, achievement, competitiveness, and outperforming others).

MAJOR RESEARCH METHODS AND MEASUREMENT TOOLS USED TO TEST GOAL THEORY

Much research examining goal orientations has used self-report survey instruments. Students are asked to complete surveys that assess students' personal goals, and their perceptions of classroom and/or school goal structures. Some researchers collect survey data at one point in time in order to get a snapshot of students' goal orientations, whereas others collect survey data at multiple time points, in order to examine changes in goals and perceived goal structures.

There are many existing survey-based measures of goal orientations. One of the most commonly used measures is the Patterns of Adaptive Learning Survey (PALS; Midgley et al., 1998). The PALS contains measures of students' personal goals, as well as their perceptions of classroom goal structures. These measures have been used with a wide range of age groups, including young children, adolescents, and college-aged students. Other measures, such as the AGQ of Elliot and colleagues (Conroy, Elliot, & Hofer, 2003) and measures developed by Dweck (e.g., Dweck, 1999) also can be used to measure students' goal orientations across a variety of domains. Most survey measures of achievement goals assess students' reasons for engaging in academic tasks; however, Nichols and his colleagues conceptualized their measures of goal orientations in terms of how students feel about learning (Nicholls, 1989).

Some researchers have used other methodologies to examine goals. For example, Patrick, L. Anderman, and their colleagues developed an observational instrument that can be used by observers to assess goal structures in classrooms (Patrick, Anderman, Ryan, Edelin, & Midgley, 2001). Turner, Meyer, and their colleagues have examined transcripts of teacher-student discourse to

examine how goals are communicated to students by teachers (Turner et al., 2002).

INDIVIDUAL AND CONTEXTUAL INFLUENCES ON DEVELOPMENT OF GOALS

Motivation researchers who study goal orientations acknowledge that both students' individual characteristics and contextual influences affect the types of goals that students adopt in various learning environments. Studies indicate that the environments in which students learn influence students' goal orientations in important ways.

Individual Differences Studies that have examined gender differences in goal orientations have produced mixed results. Many studies that have examined gender have found that males tend to report being more performance-oriented than do females (L. H. Anderman & E.M. Anderman, 1999; Roeser, Midgley, & Urdan, 1996); however, other studies have found no gender differences (e.g., Midgley & Middleton, 1997).

Fewer studies as of 2008 have examined ethnic differences in goal orientations. Results from studies that have been conducted are inconclusive. Much additional research in this area is needed. In one large-scale study, Midgley and Middleton (1997) compared goal orientation using a sample of European American and African American adolescents. Although no differences were found for performance-approach or avoid goals, African American adolescents reported somewhat higher mastery goals than did European American students. In a longitudinal study, Freeman and her colleagues found that across eight waves of data collection, African American students reported overall being more mastery oriented and more extrinsically oriented than did European American students (Freeman, Gutman, & Midgley, 2002). In a qualitative study of African American students' goal orientations, Edelin (1998) found that when students were asked to discuss their achievement goals during interviews, most of the students talked about holding extrinsic goals. Interestingly, students occasionally mentioned mastery goals, but rarely mentioned performance goals (i.e., outperforming others).

One area that has received additional attention in the literature is the relation of students' beliefs about intelligence to goal orientations. Dweck and her colleagues indicate that students who hold incremental beliefs about intelligence (i.e., they believe that intelligence is modifiable) tend to adopt mastery goals. In contrast, students who hold entity theories of intelligence (i.e., they believe that one's intelligence is a fixed entity that can not be changed) tend to adopt performance goals (Dweck, 1999).

ARE PERFORMANCE GOALS BAD?

Are performance goals bad? If studies have shown that performance approach goals are related to higher achievement, whereas few studies have shown a direct relation between mastery goals and achievement, then shouldn't teachers structure classrooms so students are challenged to reach optimal achievement as measured against "average?" While it appears clear that performance avoidance goals result in few benefits, mounting evidence indicates performance *approach* goals may have adaptive value e.g., they have been positively associated with task value, academic self concept, effort, and achievement (Harackiewicz, *et al.*, 2002).

In a series of studies, Elliot, Shell, Bouas Henry, and Maier (2005) divided students into groups of performance approach, performance avoidance, or mastery conditions. The result? When students believed their work would result in future opportunities to reap rewards, students in the performance approach group out achieved those in the mastery group. And when they thought there was no future contingency hanging on their work? They performed *just as well* as those in the mastery group. In other words, there appeared to be no penalty for being in an environment that encouraged performance approach indeed, there appeared to be benefits.

In another study, Barron and Harackiewicz (2003) examined achievement goals in a small undergraduate psychology classroom that promoted critical thinking, writing, oral presentation skills, and participation a setting the authors felt would have been conducive to a mastery orientation. Students who adopted higher levels of performance approach goals at the outset were more likely to earn a higher grade but, to also have less interest by the end of the semester, whereas those adopting mastery goals tended to demonstrate increased interest. In order to succeed in this setting, students taking a performance approach orientation would have had to go beyond mere memorization of facts and adopt deeper processing strategies. The results of this study suggest that it could be that performance approach and mastery goals serve two ends for the student achievement *and* interest.

However, others have questioned the benefits of encouraging performance approach goals as they may not

be effective across educational settings. If students are encouraged to evaluate their performance against norms, then inevitably some will be left out. For every student who achieves above the norm, one falls below it. Under such circumstances, those who already have a sense of academic efficacy will be motivated to engage in academic tasks those who have experienced failure may avoid them. Midgley, Kaplan, and Middleton (2001) noted that performance goals may be most advantageous if one is male, older, and in a competitive class where mastery goals are also encouraged, adding that school settings already tend to be predominantly performance oriented. Since the time of their writing, *No Child Left Behind* has been signed into law it is not likely classrooms have become any more mastery oriented during the intervening years.

So, are performance goals bad? While it appears that performance approach may be adaptive for students in some situations, certainly further study is needed. One thing that appears to be clear is that the greater learning context needs to be considered in answering this question including teachers' and students' long and short term goals for learning, the school and larger societal settings, and the individual characteristics of the student.

Michael S. Yough

Contextual Influences Research suggests that in addition to student characteristics, social contexts are also influential in determining students' goal orientations. More specifically, the instructional practices that are used in classrooms and schools have an impact on the types of goal orientations that students adopt (Maehr & Anderman, 1993; Maehr & Midgley, 1996; Roeser et al., 1996; Turner et al., 2002). In a given classroom, if a teacher talks about and truly focuses on mastery, improvement, and self-comparisons, then students are quite likely to adopt mastery goals and to perceive a mastery goal structure in that classroom; in contrast, if a teacher constantly talks about grades, test scores, and who is doing the best (or the worst) in class, then students are likely to adopt performance goals and to perceive a performance goal structure in that classroom.

In addition, practices that are used by the school as a whole can influence the adoption of mastery or performance goals. For example, many schools place much emphasis on the importance of the honor roll. In many schools, students' names are placed on the honor roll when they receive certain grades (e.g., an A average). Additionally, in many schools, the honor roll hangs on a highly visible bulletin board or is projected on a television monitor, where it is viewed daily by students, teachers, and visitors. When schools emphasize ability differences in this and similar ways, students are likely to adopt performance goals and to perceive that the school is performance-oriented.

Parents can also influence students' goal orientations. Parental emphasis on the importance of grades and high test scores may lead offspring to become performance-oriented students. In contrast, parental emphasis on learning and mastery encourages offspring to become mastery-goal students.

RELATIONS OF GOALS TO EDUCATIONAL OUTCOMES

Mastery and performance goals are related to various educational outcomes in important ways. When students adopt either mastery or performance goals, predictable outcomes often result.

Research frequently indicates that mastery goals are related to adaptive outcomes (see Anderman & Wolters, 2006, for a review). When students report being mastery oriented, they persist longer at academic tasks, they are more engaged with their work, they use more effective cognitive processing strategies, they report lower levels of self-handicapping behaviors, and they choose to continue to engage with tasks in the future when those tasks become optional (e.g., choosing to enroll in an additional course after the completion of a current course). Interestingly, few studies indicate that the adoption of mastery

goals is related directly to increased academic performance (i.e., higher grades or test scores). As of the early 2000s, many researchers had studied mastery-approach goals but had not examined mastery avoid goals.

The connections between performance goals and various educational outcomes are more complex. Prior to the mid 1990s, researchers often measured performance approach and avoid goals within the same scales, thus confounding these measures; later measures clearly distinguished between approach and avoid performance goals.

In general, results indicate that performance avoid goals are not related to adaptive outcomes; more specifically, studies indicate that performance-avoid goals are related to poor academic performance, low levels of academic engagement, and avoidant behaviors such as self-handicapping (Urda, Ryan, Anderman, & Gheen, 2002).

Studies examining the connections of performance-approach goals to various educational outcomes yield somewhat mixed results. Some research indicates that the adoption of performance approach goals is related to persistence at academic tasks, whereas other studies do not indicate a relation between performance approach goals and persistence. Similarly, some studies indicate that performance-approach goals are related to the use of adaptive cognitive and metacognitive strategies, whereas other studies do not yield these findings. In addition, some research indicates that the adoption of performance-approach goals is related to maladaptive outcomes, such as the avoidance of help-seeking (Ryan, Hicks, & Midgley, 1997). Despite these mixed results, several studies do indicate that there is a positive connection between course grades and performance-approach goals in college students and sometimes in younger students (see Anderman & Wolters, 2006, for a review).

Studies examining the relations of classroom goal structures to educational outcomes yield similar results. Perceptions of a mastery goal structure are generally related to adaptive outcomes, whereas perceptions of performance goal structures are often related to maladaptive outcomes. Studies examining the relations of perceived performance goal structures to academic achievement yield mixed results, with some studies indicating that performance goal structures are related negatively to achievement (E. M. Anderman & Midgley, 1997), and other studies indicating that mastery goal structures are either unrelated to achievement or related positively to achievement (Midgley & Urda, 2001).

THE DEBATE ABOUT PERFORMANCE GOALS

Debate in the educational psychology literature regarding performance approach goals has focused on revisions to

goal orientation theory (involving approach and avoid goals) in the late 1990s. Some researchers argue that performance approach goals are adaptive and can be beneficial for students, particularly when they are paired with mastery goals (Harackiewicz, Barron, Pintrich, Elliot, & Thrash, 2002). In contrast, other researchers argue that there are few benefits to performance approach goals (Midgley, Kaplan, & Middleton, 2001). These debates have important implications for the design of educational environments and for school reform. As noted by Roeser (2004), part of this debate emanates from the fact that some goal theory researchers (e.g., Midgley et al.) primarily have been concerned with issues of reforming school learning environments, whereas others (e.g., Harackiewicz et al.) have been concerned with developing theoretical models to enhance and explain individual student motivation. Interestingly, despite the debate about performance goals, the vast majority of goal theory researchers converge on the benefits of mastery goals for educational outcomes.

IMPLICATIONS FOR EDUCATORS

Nearly two decades of research from about 1985 into the early 2000s on achievement goal orientations offered educators a number of practical implications for classrooms. As educators think more critically about the types of goals that teachers and schools foster in their students, they may be better able to shape the motivational patterns adopted by children and adolescents in school settings.

One of the basic tenets of goal orientation theory is that students' goals, as well as classroom and school goal structures, can be changed. Goals can change across different social contexts. In addition, teachers and administrators can deliberately alter instructional practices to affect the social contexts of schools and classrooms.

Maehr, Midgley, and their colleagues engaged in extensive work in the early 1990s, using goal orientation theory to guide school reform. Specifically, in a series of studies of both elementary and middle grades schools, they demonstrated that the instructional practices used in schools could be changed, using goal orientation theory as a guiding framework, to make practices focus more on mastery and improvement and less on performance and ability differences. A team of researchers (including both university faculty and graduate students, several of whom had experience as classroom teachers) met with a team of school-connected adults (i.e., teachers, administrators, and parents) to critically examine the practices of the schools using goal orientation theory. These collaborative teams worked to identify practices that encouraged either mastery or performance goals. Then, over a three-year period, the teams worked to eliminate some of the

instructional practices that focused on performance goals and to enhance and increase the strategies that fostered the adoption of mastery goals. Results indicated that these changes could be successfully implemented in school settings and that student motivation was enhanced as a result of these changes (Maehr & Midgley, 1996).

Several researchers have suggested that educators can use TARGET a means of examining and realigning instructional practices according to goal orientation theory. Developed by Joyce Epstein (1989), the TARGET acronym refers to six aspects of the learning environment that are strongly related to academic motivation: tasks, authority, recognition, grouping, evaluation, and time. Several researchers have demonstrated that instructional practices can be restructured using TARGET as a guiding framework (Ames, 1990; Maehr & Anderman, 1993). Tasks can be examined and altered so that they encourage students to focus on mastering the task, regardless of the performance of other students on the task. Authority refers to how much control students have over tasks: Students will be more likely to adopt mastery goals when they have at least some choice/control over some aspects of their work. Recognition refers to how and why students are acknowledged in the classroom (i.e., for their personal accomplishments or for their performances compared to others).

Grouping refers to how students are organized socially for instruction; if students are grouped by ability, this may support the endorsement of performance goals in some students, whereas if students are grouped according to their interests, they may be more likely to adopt mastery goals. Evaluation simply refers to how students are assessed; evaluations can be based on mastering a task or on how quickly or accurately one student completes a task compared to others. Finally, time refers to how time is used in classrooms; some educators use time and structure their classes so that students can master tasks and spend the necessary time on complex tasks, whereas others structure time more rigidly and may limit the amounts of time that students can spend on tasks. If students feel rushed when working on a complex task, they may become more performance oriented and start comparing their performance to that of other students.

Eric M. Anderman

GOAL SETTING

Goal setting is an important component of students' motivation, self-regulation, and achievement in academic settings. A goal is a behavior or outcome that one is consciously trying to perform or attain. Goal setting refers to the process of establishing that behavior or outcome to serve as the aim of one's actions. Goals can exert positive effects in achievement settings by directing learners' attention to important activities and away from distractions and by mobilizing their effort and persistence directed toward goal attainment. Given the centrality of goals to classroom learning, it is important that students set goals that are likely to have desirable effects.

TYPES OF GOALS

Simply having a goal does not automatically benefit a student's academic performance. Researchers such as Bandura (1986) and Locke and Latham (1990, 2002) have identified various goal properties and have investigated how different goals link with achievement outcomes.

Goals may be cast as absolute or normative. An absolute goal has a fixed standard, such as reading one chapter in a book in one hour. A normative goal is relative to the attainments of others, such as being the first one in class to finish an assignment.

Goals can be distinguished according to how far they extend into the future. Goals may be relatively close at hand (proximal) such as reading one chapter tonight, or more long term (distant) such as reading one chapter by the end of the current week. Proximal goals lead to higher motivation directed toward goal attainment than do long-term goals (Bandura, 1986). Proximal goals are especially beneficial for children because they have short time frames of reference and are not fully developmentally capable of representing long-term outcomes in thought.

Goals also can be distinguished according to the specificity of their performance standards. Goals that incorporate specific standards (e.g., complete 20 problems in one hour) are more likely to enhance motivation and learning than are general goals (e.g., do your best) because specific goals better describe the amount of effort needed to succeed. Motivational benefits are not as great

with general goals because almost any level of performance satisfies the standard (Locke & Latham, 2002).

An important goal property is difficulty, or how hard it is to attain the goal. In general, difficult goals (e.g., read a 30-page chapter tonight) boost motivation better than do easier goals (e.g., read five pages tonight), because students persist longer and expend greater effort when they pursue difficult goals. However, goal difficulty and motivation do not bear an unlimited positive relation with one another. Students are not motivated to attempt goals that they believe are impossible to attain. Difficult goals do not raise motivation and learning in the absence of the skills needed to attain them. Goals are motivating when learners view them as challenging but attainable (Locke & Latham, 2002).

Another way to differentiate goals is according to students' level of commitment to attain them. Goals do not affect performance in the absence of commitment (Locke & Latham, 1990). The goal properties identified above can help foster commitment. Students typically are more committed to attempt goals when they are specific, proximal, and moderately difficult, than when they are general, distant, and either overly easy or difficult.

Finally, goals can be distinguished by what students ultimately are trying to accomplish. A process or learning goal refers to what knowledge, behavior, skill, or strategy students are trying to acquire. An outcome or performance goal denotes what task students are trying to complete. While working on algebra homework, a student may have a goal of learning how to solve two equations in two unknowns (process) or a goal of finishing the homework assignment (outcome). Although both types of goals can motivate behavior, they can have different effects on learners' beliefs and cognitive processes. As Pintrich has shown, process goals focus attention on the skills needed to learn. Students often evaluate their progress in learning, and the belief that one is learning can enhance motivation. In contrast, outcome goals focus attention on completing tasks. These goals can lead learners to compare their work with that of others, which can lower motivation among students who are not making adequate progress.

GOAL SETTING EFFECTS ON ACHIEVEMENT OUTCOMES

To explain why goals affect achievement behaviors, researchers have advanced different theories. Locke and Latham (1990) proposed that the key components are goal choice and commitment. Goal choice includes the goal people are trying to obtain and the level at which they are trying to attain it. Goal commitment refers to how enthusiastic people are about a goal or how determined they are to achieve it. Locke and Latham identified several factors

that affect goal choice and commitment, including personal-individual factors such as skill level and previous performance and social-environmental factors such as group norms and the nature of authority and feedback. Because this theory was developed and tested in organizational settings, it places strong emphasis on external factors.

Bandura's social cognitive theory (1986) posits that human functioning results from reciprocal interactions among personal factors (e.g., cognitions, emotions), behaviors, and environmental conditions. There are two primary cognitive sources of motivation (personal factors): goals and expectations. Goals help to focus and sustain effort toward task completion. As people work on tasks they compare their performances with their goals. Positive self-evaluations of progress raise self-efficacy (discussed below) and sustain motivation. The perception of a discrepancy between present performance and the goal can create dissatisfaction and raise motivation for goal attainment.

Bandura's theory identifies two types of expectations. Outcome expectations are beliefs about the likely consequences of actions. Based on their past experiences and observations of models in their environments people form beliefs about the likely consequences of given actions. People are likely to act in ways that they believe will lead to desired outcomes. Outcome expectations can motivate behavior over long periods when people believe that their actions will eventually result in success.

Efficacy expectations, or self-efficacy, refers to personal beliefs about one's capabilities to learn or perform actions at designated levels (Bandura, 1997). Self-efficacy is not the same as an outcome expectation. Students may believe that studying diligently for an exam will produce a high grade (positive outcome expectation) but may doubt their capabilities to study diligently (low self-efficacy). Often, however, self-efficacy and outcome expectations are related. Students with high self-efficacy for doing well in school expect to receive good grades for their coursework. Both types of expectations can affect motivation.

Bandura (1997) noted that people gauge their self-efficacy from their performances, observations of models, forms of social persuasion, and physiological indexes (e.g., heart rate). Actual performances offer the best source of information; successes generally raise and failures may lower self-efficacy. Students receive information about their capabilities by observing others perform. Observing similar others succeed can raise observers' self-efficacy. Social persuasion, such as when a teacher tells a student "I know you can do this," can raise self-efficacy, but this increase will not last long if students perform poorly. Physiological symptoms can be informative of self-efficacy. When students

Effective athletic training places a strong emphasis on both proximal and process goals. ©RICHARD HAMILTON SMITH/CORBIS.

notice that they are less anxious studying for an exam, they may feel more self-efficacious about performing well on it.

Bandura's social cognitive theory (1986) contends that learners set goals that they feel self-efficacious about attaining and believe that when attained will result in positive outcomes. They evaluate their goal progress as they work on the task. Their self-efficacy and motivation are strengthened when they believe that they are making progress toward their goals. Self-efficacy is further enhanced when learners attain their goals, as well as their motivation to set and pursue new goals.

Goal setting also is a key component of self-regulation, or the process by which students activate and sustain cognitions, behaviors, and affects systematically oriented toward the attainment of goals. Zimmerman's three-phase model of self-regulation (2000) includes forethought, performance/volitional control, and self-reflection. The forethought phase precedes performances and refers to processes that set the stage for action. The performance/volitional control phase includes processes that occur during learning and affect motivation and action. During the self-reflection phase, learners reflect

on their performances and determine whether changes in behaviors or strategies are needed.

Goals and self-efficacy are active throughout the model. In the forethought phase, learners set goals and have a sense of self-efficacy for attaining them. As they work on the task they mentally compare their performances with their goals to determine progress. Their self-efficacy is sustained when they believe that they are making goal progress. During self-reflection learners determine whether their present approach is effective. If they feel self-efficacious for succeeding but believe that their present strategy is not working well enough, they may alter their strategy by working harder, persisting longer, deciding to use a different method, or seeking help from others. These self-regulatory processes promote learning, motivation, and self-efficacy.

GOAL SETTING RESEARCH IN EDUCATION

Goal setting research in education has established the importance of specific, proximal, and moderately challenging goals as beneficial for motivation and learning. Schunk has conducted several studies investigating these

variables. In these studies, elementary school children received instruction on arithmetic operations and opportunities to practice solving problems. In one study some children received a specific goal denoting the number of problems to complete, whereas others were given a general goal of working productively. Compared with the general goal, the specific goal promoted higher self-efficacy and mathematical achievement.

Bandura and Schunk conducted a similar study investigating goal proximity. Over several sessions children received instruction that explained and demonstrated subtraction operations and opportunities to practice solving problems. Proximal-goal children were asked to complete a portion of the instructional material during each session; distant-goal children were told to complete all of the material by the end of the last session. Proximal goals raised motivation during the sessions, as well as children's self-efficacy and subtraction achievement, better than distant goals.

Schunk's research also has addressed goal difficulty during school learning. In one study, children received long-division instruction and practice opportunities. All children received the same instruction and practice time. Some children were given a more difficult goal (higher number of problems to complete), whereas others received an easier goal (lower number to complete). Difficult goals led to higher motivation during learning, self-efficacy, and skill acquisition.

Goal progress feedback provides information about progress toward goals and can promote self-efficacy and motivation when students cannot derive progress information on their own. It often is difficult for children to know whether their reading comprehension or their written expression is improving. Research by Schunk and Rice with children with reading difficulties showed that giving children feedback on how well they were learning to use a comprehension strategy improved their reading comprehension self-efficacy and achievement. Schunk and Swartz obtained comparable results in writing achievement and found that self-efficacy and achievement gains generalized to different types of writing assignments and maintained themselves over time.

Researchers have addressed how process and outcome goals affect motivation, learning, and self-regulation. In the Schunk and Rice study, children were taught a comprehension strategy. Some received a process goal of learning to use the strategy to answer comprehension questions, whereas others were given an outcome goal of answering questions. The process goal, coupled with progress feedback on how well the children were using the strategy, promoted self-efficacy and achievement the best. With college students, Schunk and Ertmer found that a process goal of learning computer applications led

to higher self-efficacy, self-judged learning progress, and strategy use, compared with an outcome goal of performing the applications.

Research by Zimmerman and Kitsantas found benefits from shifting from process to outcome goals. High school students were taught a writing revision strategy. Some students received a process goal (following steps in the strategy) or an outcome goal (number of words in sentences). Others initially were given a process goal but then were advised to shift to an outcome goal. Learners who changed goals as their revision skills developed demonstrated higher self-efficacy and skill than students who pursued either the process or the outcome goal.

IMPLICATIONS FOR EDUCATORS

Goal-setting research in school settings shows that students' learning, motivation, and self-regulation can be improved when students pursue goals that are specific, proximal, and moderately difficult, receive feedback on their goal progress, focus their attention on learning processes, and shift their focus to outcome goals as their skills develop. These points have implications for educators who desire to use goal setting systematically.

Much educational planning is based on proximal, specific, and moderately challenging goals. Teachers typically plan daily lessons around specific student learning outcomes. Content difficulty usually is low initially to ensure that students acquire skills but increases as students become more proficient.

Students may need to be taught how to set goals that are proximal, specific, and moderately difficult. Many students are not realistic about the steps involved in completing a project or about how much time is required to complete those steps. Goal-setting research suggests that the key to completing a long-term task is to divide it into short-term goals. Educators who work with high school students who have to write a research paper can help them subdivide this task into proximal and specific steps, such as deciding on the topic, doing library and Internet research, outlining the paper, and writing the first draft. Timelines can be established for the subgoals. As students gain experience with goal setting, they will be able to set realistic goals on their own.

Educators can help students focus on process goals by providing feedback that stresses processes, such as how well students are using a strategy, budgeting their time, and completing subgoals. However, as the research by Zimmerman and Kitsantas showed, outcome goals can be highly motivating and lead to skill gains once students have acquired some competence. Teachers can shift students to focusing on outcome goals that are self-referenced such as how well students are doing currently compared with how they did previously, rather than socially referenced such as

how well they are doing compared with how classmates are doing. These social comparisons will not raise self-efficacy among students who perceive that they are performing worse than their peers.

Finally, goal setting theory and research underscore the importance of developmental factors. Because children have short time frames of reference, immediate goals are motivating, whereas long-term goals are not. Short, focused lessons reflect this idea. With development, students are better able to cognitively represent long-term outcomes. Teachers can work with students to help them break long-term goals into short-term subgoals, establish timelines, and assess their progress toward their goals. Teachers also can assist students in evaluating their capabilities to engage in these tasks, which will help to develop their self-regulatory competencies. Students who graduate from high school with a mindset that includes the importance of setting goals and assessing progress will be well prepared to meet future educational and life challenges.

GRADING

Grading is an evaluative practice that assigns letters, marks, numbers, or descriptions that indicate the level of student performance. It is carried out to provide meaningful feedback to students and parents about what a student has learned. Grading requires professional judgments and evaluations of student work. As such, grading practices can vary significantly from one teacher to another. There is also considerable variability in what is included in determining grades (i.e., student achievement, effort, participation, cooperation). These differences have been documented with research that shows that, in the main, teachers' grading tends to include a hodgepodge of various factors (Brookhart, 1994; McMillan, 2007). There is little consistency in grading practices across school and teachers, even within the same school, resulting in the use of different inputs and judgments.

PURPOSE OF GRADING

Grades have been used to serve three purposes: (1) ranking students, (2) reporting what students have learned and are able to do, and (3) providing feedback to improve learning and motivate students (Brookhart, 2004). In the past, one of the main reasons for grading students was to show how a student's performance compared to that of other students. This kind of comparison is called *norm-referenced*. With this approach, higher grades (As and Bs) are awarded to students who perform best in comparison with the performance of other students, and lower grades (D and F) are given to students whose relative standing is the worst. Students in the middle are "average," with a C grade. This approach has been called *grading on the curve*.

Knowing which students are the best or highest is an important function of schooling, but many contend that the competitiveness among students that results is detrimental to learning and interpersonal relationships (O'Connor, 2002). If ranking is used exclusively, students are more interested in outdoing one another than learning, and this encourages the designation of "winners" and "losers." Most importantly, grades determined by ranking may not indicate how much students have learned. It is possible that students learning little are given high grades because their performance is better than students who learn very little.

The primary reason for grading is to give students, parents, and teachers information about the achievement of goals, objectives, and standards (Marzano, 2006; McMillan, 2008; Stiggins, 2008). Grades are awarded based on student performance that is compared to pre-established levels of competence. This kind of grading has been called *criterion-referenced*, *standards-based*, *mastery*, or *absolute*. The focus is on what students know and can do rather than relative standing. Theoretically, all students can obtain the highest grade, and all students can also get a low grade.

A key component of standards-based grading is the determination of what determines designations such as mastery, proficient, or passing. This requires clarity in the criteria that are used to judge student performance and depends on who establishes the criteria. An important development is the use of several levels of performance or benchmarks that can be used to give specific feedback and to rank students (Guskey, 2008; Guskey & Baily, 2001). This kind of grading results in a much more supportive learning environment that fosters positive relationships among students and teachers.

FEEDBACK TO STUDENTS

Grades can be used to provide feedback to students about their performance by showing the ways in which proficiency was demonstrated, and what is needed for a higher grade. This is important for student learning because students have a better understanding of why they received the grade. When provided in sufficient detail, feedback can tell students where there were mistakes, areas of strength and weaknesses, and what subsequent steps are needed to improve their understanding. Feedback is usually provided with prepared narratives that accompany grades, and/or with specific, individualized teacher comments. When feedback is specific, individualized, ongoing, and immediate it has the greatest impact on student learning. In using what is called *formative assessment* feedback is an essential component to help students become more proficient as they learn. General comments such as “good job” or “very good” are not very helpful.

A key distinction with feedback is whether it is primarily evaluative or descriptive (Brookhart, 2004). *Evaluative feedback* is provided in the form of rewards, praise, and positive expressions and non-verbal messages. For young children (grades K-2) these may take the form of stickers, “smiley faces,” or treats. For older students (grades 3-12) evaluative feedback is given primarily through letter grades. *Descriptive feedback* is structured to provide the student with information that relates specifically to the learning objectives or standards. This consists of specific, targeted praise and verbal and written messages that show students what they have learned and

what remains to be learned, sometimes with an emphasis on student self-assessment and suggestions for further learning.

Many teachers use both kinds of feedback (Brookhart, 2004; McMillan, 2007). For early grades (K-2) students are usually rated with a simple scale, such as satisfactory/unsatisfactory or needs improvement/partially proficient/proficient. When these ratings are used there is usually further information that is more specific. Older students typically receive letter grades, though the trend is for giving more descriptive feedback in addition to letter grades. The standards-based trend in American education has emphasized evaluative grading of all students, regardless of age (McMillan, 2008). Students of all ages can learn to use descriptive feedback to improve learning.

GRADING AND STUDENT MOTIVATION

In one way or another, grading affects student motivation. If grades are viewed as extrinsic rewards students tend to be motivated more by doing what is needed to obtain the reward (or avoid the punishment) than by improving their understanding of the content. In contrast, when the reinforcement focuses on improving knowledge, understanding, or skills, getting the extrinsic reward is viewed as secondary to the intrinsic reward of learning and motivation. This is a mastery orientation. Students with this type of motivation see the value in what is learned, prefer challenging tasks, stay engaged longer, display independent learning, and have positive attitudes toward learning.

EFFORT AND IMPROVEMENT

A longstanding issue in grading is whether to use student effort and improvement as factors that effect final ratings and letter grades. Effort is often assessed by participation, completion of work, extra credit, and teacher observation. It is problematic to include effort as part of a grade that purportedly represents achievement, primarily because it is difficult to measure accurately, and because if included in grades it distorts the meaning of the grade. But effort is important in learning, so it needs to be considered. The recommended approach to assessing effort is to grade and report it separately from achievement (Brookhart, 2004; Guskey & Bailey, 2001; Stiggins, 2008).

Improvement is also difficult to incorporate into grades. While actual learning is represented by how much students' achievement changes, grades typically do not include this factor. However, improvement is often considered in an anecdotal manner and may affect the grade,

especially for students who initially demonstrate low performance.

In summary, grading is important for several reasons and will continue to be used. Teacher judgment is always an important factor; there is no completely objective approach. The relationship of grading to learning and motivation is important. Standards-based education models have promoted grades that reflect primarily student achievement, with little or no reflection of effort or improvement. The validity and fairness of grading depends on the match between what grades are claimed to represent and what is actually included in the grade. Feedback is an essential aspect of grading that can have positive benefits for both learning and motivation.

GRAHAM, SANDRA (HALEY)

1945-

In 1982 Sandra Haley Graham completed her doctorate in educational psychology at the University of California, Los Angeles. Before coming to Los Angeles, Graham graduated from Barnard College (B.A., 1969) and from Columbia University (M.A., 1970). Graham then taught junior high school in Newton, Massachusetts, for three years. Curious about the behavior and academic orienta-

tion of some of her junior high school students, she began to consider the unique socio-cultural experiences and needs of minority children, particularly African American boys.

At UCLA Graham worked with social psychologist Bernard Weiner on attribution theory. Graham's early research used attribution theory as a framework to understand individual, contextual, and interpersonal factors influencing children's achievement motivation. Her research examined how others consciously and unconsciously may send messages to students that may undermine their own sense of self. Graham recalled having such an experience as a college freshman during final exams week. She got a note from the professor urging her to attend an extra help session, and immediately Graham began to doubt herself, wondering why the professor had singled her out for help. She realized at that point that unsolicited offers of help can undermine a person's self-concept by communicating a message of perceived low ability. In *Communicating Low Ability in the Classroom: Bad Things Good Teachers Sometimes Do* (1990), Graham describes how praise and well-intentioned yet unsolicited assistance communicates perceptions of low ability that may reduce children's beliefs in their own efficacy and undermine achievement motivation.

Graham was a pioneer in examining the relationship between the social context and behaviors and how they are linked to children's academic engagement. Research has consistently supported that even the most capable and supported students likely will not achieve their potential if they are not engaged in their academic lessons. Graham noticed that during her work in classrooms that many students who were not engaged academically had behavior problems and were identified as aggressive by their peers and teachers. More troubling, she noticed that these students' predicaments were only negatively amplified by the time spent in principals' offices. Continuing her focus on children's attributions, Graham incorporated into her repertoire an examination of the determinants of aggression among minority male youth. Consistent with her hypothesis, Graham found a link between attribution, affect and action in that aggressive males were more likely than non-aggressive males to assume that a peer's negative behaviors were intentional, become angered, and respond with aggression of their own.

Graham recognized that in order to address the needs of an increasingly diverse population, diversity must be represented and valued in the literature. This lack of diversity was the impetus for her article "Most of the Subjects Were White and Middle Class: Trends in Published Research on African Americans in Selected APA Journals" (1992). This work highlighted the lack of ethnic representation in research of the time and was a call for more representation in research.

Graham never lost sight of her ultimate goals for her research. Her next tasks involved bridging theory and practice by designing and conducting a hostile-attribution retraining program in collaboration with her former student Cynthia Hudley. This line of intervention work included Best Foot Forward, a 32-lesson curriculum focused on enhancing social and academic motivational skills. The social skills component was comprised of two sections, impression management and attributions of intent. The academic motivation component was divided into sections covering intermediate risk taking, goal setting, task focus, and failure attributions. This curriculum has had an overall positive impact on aggressive participants: There were increased adaptive responses to conflict and decreased hostile attributions. Academically, participants made fewer external attributions for failure and evinced more adaptive goal setting. Additionally, teacher ratings of cooperation/motivation and persistence increased significantly for intervention participants. This work highlights the value of theory-guided, multi-method, student-focused research in education.

Graham's research has included topics ranging from students' achievement values, affirmative action, peer victimization and harassment, to the cognitive competence of juvenile offenders. Her 2006 work with Janna Juvonen focused on a longitudinal investigation of the importance of school and classroom ethnic compositions for students' social-psychological adjustment and peer relationships both within middle and high school as well as across the school transition. The body of research from this data identifies requirements for optimal learning and socialization for all students, ethnic minority and non-minority alike. Findings support that ethnic diversity in classrooms and schools reduces students' feelings of victimization and vulnerability as a result of a balance of power among ethnic groups. Contrary to what one might expect, in non-diverse classrooms, victimized students who are members of the ethnic group that is the numerical majority are particularly vulnerable for maladaptive and destructive self-appraisals.

Graham received an Independent Scientist Award funded by the National Institute of Mental Health and an Early Contribution Award from Division 15 (Educational Psychology) of the American Psychological Association. She is a former Fellow at the Center for Advanced Study in the Behavioral Sciences in Stanford, California. As of 2008, Graham was a professor in the Graduate School of Education and Information Studies at the University of California, Los Angeles.

GUIDED PARTICIPATION

Guided participation refers to the process by which children actively acquire new skills and problem-solving capabilities through their participation in meaningful activities alongside parents, adults, or other more experienced companions. Guided participation emphasizes the active role of the child in learning and cognitive growth and the complementary role of parents and other caring adults in supporting, assisting, and guiding the child's intellectual development. Support includes both explicit verbal and non-verbal guidance as well as more subtle direction through the arrangement and organization of children's interactions with the environment. Guided participation occurs throughout the course of childhood as children progress from a peripheral and dependent role to one of increased autonomy and responsibility while they strive to master the challenges posed by the surrounding social and cultural milieu (Rogoff, 1990, 1998; Gauvain, 2001).

Casual observations of parents interacting with their young children typically offer many examples of guided participation. In the grocery store 3-year-old Alberto holds the shopping list for his mother and studies a box of Cheerios as he sits in the shopping cart. Alberto's older brother, who is 7, is searching for a can of soup that says "tomato." When he has found the soup and they move on to the next aisle, his mother will have another job for each of them. Alberto's mother is skillfully engaging her boys with the shopping, and the children are enjoying themselves in an activity with their mother, feeling competent with the tasks she sets for them as they learn about their social world.

The term guided participation was introduced by the neo-Vygotskian, Barbara Rogoff, in her book *Apprenticeship in Thinking* (Rogoff, 1990) to clarify the nature of children's cognitive development within the framework

of sociocultural theory. Vygotsky claimed that the ability to engage in higher mental functions, the distinguishing feature of human psychology, is rooted in social interaction. Thinking emerges from early social interactions in which the child works with others to solve problems. To insure children's success, more experienced partners direct their assistance to the child's *zone of proximal development* or potential development. This is defined as "the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers" (Vygotsky, 1978, p. 86.). This approach differed from prevailing views of cognitive development since the focus was not on what the child could do alone, but was future oriented, focusing on what could be done with help from others.

The notion of zone of proximal development offered a new way of thinking about verbal interactions and cognitive growth. Because language plays an important role in structuring social interactions language and communication patterns serve as one type of "scaffold" supporting the child's developing capabilities. A number of researchers looked for evidence demonstrating that appropriate talk on the part of adults supports children's problem-solving success (Berk & Winsler, 1995; Diaz, Neal & Amaya-Williams, 1990; Wood, Bruner, & Ross, 1976).

Guided participation expands upon adult talk as a scaffold by broadening the social context and emphasizing the role of the child in relation to the adult. Gauvain (2001) notes that in this view, "the child is not merely a learner, or a naïve actor who follows the instructions or prompts of the more experienced partner. Rather, the child is a full participant, albeit a participant of a specific type characterized by individual and developmentally related skills, interests and resources" (p. 38). Children's participation in the organized routines and practices of the social community as well as engagement in more didactic experiences are all essential to cognitive development.

Some of the most compelling illustrations of guided participation are evident in parents' interactions with young children. These show that guided participation includes two focal processes: "creating bridges" to make connections to new ideas and skills and "structuring children's participation" in activities by creating opportunities for their involvement and through social support and challenge in activities and roles valued in their community (Rogoff et al., 1998).

While examples of adult-child interactions can be found anywhere people interact in meaningful activity, schools are critical contexts for guided participation. Particularly good illustrations can be found in child-

centered or learner-centered classrooms where children are actively engaged in learning activities that have been carefully planned by the teacher, as the following example shows.

Sasha is one of the less skilled writers in her first-grade class. She has completed a drawing and the teacher would like her to write something underneath the completed picture but she doesn't seem to know how to start. Sasha's teacher uses a technique that relies on graphic mediators to support children's early writing attempts. "Let's write something about your picture," the teacher says. Sasha replies, "They are eating at McDonalds." The teacher writes the five words Sasha has dictated on a strip of paper she has placed under the picture. "Do you see what I wrote? I wrote exactly what you said!" The teacher then takes another strip of paper and draws five horizontal lines along the edge, one for each of Sasha's words. Then she re-reads the sentences, pointing to the lines. Sasha will copy the sentence, one word on each line.

As Sasha becomes more confident of her writing the teacher will decrease the support she provides. Rather than provide the model, the teacher may simply draw the lines, one for each word, to help Sasha remember her sentence and to guide the spacing of her words. With further practice Sasha will be able to write a sentence independently. Sasha's teacher has supported her participation in the writing activity through sensitive and individualized guidance, adjusting the help she offers in response to the needs she observes in Sasha. Sasha and her teacher working together illustrate a child learning in the zone of proximal development.

THE CHILD IN A SOCIAL CONTEXT

The sociocultural view of the Vygotskians and neo-Vygotskians (including the notion of guided participation) differs from more familiar American and western European approaches to learning and development. This is most evident in the assumptions about the nature of the individual as a learner and the nature of the environment in which learning occurs. Classical learning theories such as behavioral analysis or social learning theory emphasize a strong distinction between the learner and the environment. According to these mechanistic perspectives, individual learning results from some action of the environment on the individual. For example, the learner is rewarded for new behavior or the learner responds to a model in the environment. The learner is passive, awaiting direction for the environment. Conversely, the environment can be fully planned, and if done correctly, fully shape and direct behavior.

A second view, also at odds with the Vygotskian notion of guided participation, is the organismic approach of many developmental psychologists, including Jean Piaget (1896

A COMPARISON OF GAGNÉ'S COMPONENT SKILLS APPROACH WITH GUIDED PARTICIPATION APPROACH TO LEARNING

Both Gagné's component skills approach and Rogoff's guided participation approach focus on learning through varied instruction. However, influenced by behaviorism and information processing theories, Gagné suggests that the skills needed for a task could be analyzed and taught as separate components in a hierarchical order from lower skills to higher ones. Indeed, he defines instruction as "the set of planned external events which influence the process of learning and thus promote learning" (1974, p.5). Yet, it still maintains the concept of knowledge acquired by learner, which Rogoff's notion of guided participation shares. Bringing Piaget's cognitive learning and Vygotsky's sociocultural learning theories together, Rogoff views instruction as an interactive process in which the learners participate in the activity guided by sociocultural values and systems. A more skilled peer or adult who jointly participate in the process gradually transfers the responsibility of activity to the learner. Yet, there is no external sequential instruction planned and applied either by instructor or learner. Because guided participation approach is drawn from cross cultural community contexts, it has been widely applied to natural learning settings in early childhood and occupational learning fields, whereas Gagné's component skills approach has been utilized by instructional and curricular design in both educational and technical military settings.

Zeynep Isik-Ercan

1980). From this vantage point, changes within the developing child are critical for understanding changes in children's behavior. These "within child" changes include physical as well as mental structures, and until they are formed learning is constrained. For example, children's

expressive language capabilities result from developing physical characteristics, and these are largely separate from environmental or experiential factors.

Both of these orientations assume that the individual and the environment are separable, a notion at odds with guided participation. Rather than focusing on the learner and the guiding "other" as independent, with one being active and the other passive, from a guided participation perspective, both the child and the environment (particularly the social environment) are active. The individuals and the social context in which they function are always linked, and the appropriate focus is the dyadic interaction within the real world. How learning processes work can be understood only by contextualizing the learning activity (see Gauvain, 2001, and Rogoff, 1990, for excellent discussions).

ORIGINS OF GUIDED PARTICIPATION CONCEPT

The construct of guided participation is grounded in the work of Russian psychologist Lev Vygotsky and the approach to cognitive development attributed to him in the early 20th century. This approach is known as the sociocultural perspective. Vygotsky and his colleagues were deeply influenced by the Marxist foundations of the new Soviet Union. One of the early goals of the Soviet regime was to bring literacy to the masses. Language and literacy are both tools of culture, and their use transforms mental capabilities. Vygotsky and his contemporaries were interested in understanding the impact of this effort as well as other aspects of the social environment on children's learning.

Although Vygotsky himself did not use the term guided participation, it shares several key notions with his work. The early socioculturalists were interested in the processes of social mediation and mind. They downplayed the idea of the individual knower separated from a social context; instead, they emphasized the role of the dyad or social group embedded in "activity." At the time, the field of psychology was still in its infancy and very little was known about the mind, society, and the influences of culture upon thinking.

The work of the Russian psychologists was barely known to western European and American scholars. Some of their work was censored within Russia and much of it was not translated into English until the 1970s and 1980s. At the same time American psychologists were looking for alternative ways to conceptualize cognitive development. The shortcomings and limitations of Piaget's model of cognitive development were becoming evident to some. New findings from cross-cultural psychology were raising new questions about the universality of cognitive structures, an idea at the

core of Piaget's theory. However, it was not clear how new findings in cross-cultural psychology should be interpreted. Cognitive psychology, rooted in information processing, was also becoming popular, but many researchers were unhappy with the excessively mechanistic, "machine-like" models of human functioning the early information processing models offered.

At the same time that Vygotsky's later work was appearing in the United States other cultural approaches to the study of human behavior were emerging. Some of this work was being conducted by anthropologists. This work was done outside university laboratories and relied instead upon ethnographic and field-based methodologies. These approaches focused on studying behavior as it is situated or as it occurs in the context of the real world. Knowledge was viewed as a highly valued social practice rather than something "in the head" (Lave, 1991). The workplace and communities, and the practices, routines, and talk that occurs within them were an important focus of study because they reveal the understandings and representations of participants (Heath, 1991; Wertsch, 1985).

An illustration of this is the work of Jean Lave. Lave worked in Africa, studying everyday cognition among workers in a tailor shop. She studied the rich repertoire of cognitive skills deployed by tailors in their work at the shop and studied the processes by which novices learn their craft. Tailors are trained through an apprenticeship. The apprentices learn their craft in a busy shop, not in a learning environment separated from world (as is school). They are surrounded by masters and other apprentices all engaged in the target skills at varying levels of expertise. They are expected to participate in activities that contribute directly to the production of actual garments, advancing quickly toward independent, skilled production (Collins, 2006, p. 32).

Lave & Wenger (1991) emphasize the movement of the learner from a peripheral position to a central position in activity. As Collins notes, guided participation and coaching are especially powerful forces for learning in the tailor shop. In the tailor shop, learners were mastering complex tasks that occurred with a web of memorable associations, all in highly meaningful contexts. Learning and teaching were highly situated and highly focused on the specific skills needed for the task.

Apprentices learn domain-specific skills through observation, coaching, and practice. The apprentice then attempts to execute the process with guidance and help from a master through a process of coaching. Collins explains this as follows:

A key aspect of coaching is guided participation: the close responsive support which the master provides to help the novice complete an entire task, even before the novice has acquired every

skill required. As the learner masters increasing numbers of the component skills the master reduces his or her participation, providing fewer hints and less feedback to the learner. Eventually, the master fades away completely when the apprentice has learned to smoothly execute the whole task. (Collins, 2006, p. 48)

ILLUSTRATIONS OF GUIDED PARTICIPATION

Some educators and cognitive psychologists have extended the ideas of Lave and Wenger (1991) to the design of instructional models useful in elementary and secondary education (Collins, 2006). Developmental psychologists have focused on issues in children's learning and cognitive development, often with a focus on parent-child interactions and the influences of these processes on higher mental capabilities (Cole, 2006; Gauvain, 2001; Rogoff, 1998; Wood, 1998).

Rogoff notes that while Vygotsky was primarily interested in the development of the mind through interpersonal interaction, he placed a great deal of emphasis on the relationship between language and thinking. Rogoff argued that the child was capable of developing thinking even when the culture placed less emphasis upon language and writing. She demonstrated this in her research with Mayans in Mexico, many of whom did not write or engage in excessive amounts of verbal interaction (Rogoff, 1998).

Gauvain (2001) notes that guided participation offers a fuller account of the child's active role in cognitive change, along with the significance of social interactional context. Guided participation can include notions such as scaffolding, coaching, and tutoring, but it also extends to broader views of supportive context for learning and development beyond the adult or more experienced partner. Such a context includes the myriad ways in which adults structure experiences for children and hence enable children to move from positions of peripheral involvement to full involvement within the community (Lave & Wenger, 1991).

Finally, an essential component of guided participation is the notion of *intersubjectivity*. This is the process by which two individuals achieve a joint focus on a problem. Intersubjectivity must be mutual, but even young infants participate in the process. Research shows that infants as young as 3 months can shift focus and visual engagement with their mothers. This type of interaction provides the starting point for intersubjectivity (Bruner, 1985; Tronick, 1982). While adults can establish general goals for children, and the adult can direct and scaffold children's performance, fine tuning and adjustment to the mutual needs of the particular individuals participating in the

interaction is needed for optimal learning and meaning making.

CONTRAST WITH TRADITIONAL VIEWS OF LEARNING

The first way guided participation differs from traditional views of learning concerns the assumptions about the nature of the learner. Learning in the traditional sense assumes that the learner can be clearly differentiated from the environmental setting. Instead, it is assumed that children's activity is intimately linked with the social context in which it is occurring. Guidance can be provided in many different ways, close at hand (e.g., the parent leading the child through a game) or more distal, as when a teacher has carefully selected and arranged materials for small groups of children to use in a learning center. In both cases, the adult begins with a general plan, but then adapts and fine tunes the plan in response to the child. The adult works to achieve a level of intersubjectivity with the child. This allows the adult to adjust and fine tune to meet the child optimally. One metaphor is to view the learner as following a path to an endpoint or destination specified by the adult. The child discovers the path. The adult posts trail markers if and when they are needed along the way. The adult cannot post the markers before the journey because the precise path the child will try to pursue is not known.

Second, unlike traditional views of learning, it is assumed that the meaning of behavior for the child will change over time. First efforts may look like play, or childish imitations. Yet these early attempts are the first steps towards mature, independent, self-directed activity. With time, and the appropriate environmental support, children will be able to carry out the behavior more independently. Later, children will carry out the behavior with a different understanding of why they are doing it, why it works, and how it is understood by others.

For example, children's first attempts at writing may be scribbles on a page, following a period of observing others writing with crayons on paper. Later, children will understand that these marks on paper can be used to communicate with others. Initially the action of "writing" is an exploration of the physical world (crayons on paper) and a way to become part of the group of other children marking on papers with the adult. In another year or two, the children will sit at their tables and writing, but it will have an entirely different meaning. Perhaps they will be writing their names.

Third, while traditional views approach learning as a strictly cognitive process, guided participation unifies the cognitive, social, and emotional dimensions of behavior. The focus is the whole person; the social and the emotional cannot be separated from the cognitive (see

Rathunde & Csikszentmihalyi, 2006). The interpersonal relationship between the partners supports the give and take necessary for children to appropriate and acquire new competencies. While the more knowledgeable partner sets broad goals for the interaction, adaptations to the needs of the individuals must be made. Again, this is particularly evident in parent-child interactions with young children.

PREVALENCE OF GUIDED PARTICIPATION CROSS CULTURALLY

Rathunde & Csikszentmihalyi (2006) note that the basic processes of guided participation are universal. In all cultural settings, parents and children must arrive at a mutual interpretation of a situation that allows intersubjectivity, or a common focus of attention and shared presuppositions. This is substantiated by findings from cross-cultural research comparing parent-toddler dyads from four cultural settings: Utah; Mayans in Mexico; Turkey, and India. Results demonstrate striking similarities, as well as distinctive differences, across these settings (Rogoff, Mistry, Goncu & Mosier, 1993; Packer, 1993).

The benefits of guided participation are grounded in maintaining the child/learner in the zone of proximal development (Rathunde & Csikszentmihalyi, 2006; Vygotsky, 1978). A number of studies confirm that guided participation is beneficial to children's development. They note that parents' use of guided participation has been linked to infants' and toddlers' communicative competence, to improvement in children's seriation skills, and to greater exploration of novel objects by 3- to 7-year-olds. Wood and Middleton (1975) note that when mothers adjusted their instruction to their children's needs by guiding at a slightly challenging level and adapting their behavior based upon their children's successes, children performed more successfully on a complex building task. Importantly, it was not the number of interventions the mother made but the quality of the interventions that was important (Rathunde & Csikszentmihalyi, 2006, p. 498).

Some illustrative examples of guided participation are evident in the research reported by Rogoff and her colleagues (Rogoff, Mistry, Goncu, & Mosier, 1993) comparing U.S. mother-child dyads with Mexican Mayan mother-child dyads. All mother-child dyads were observed in their homes as they interacted with selected materials, such as a baby doll, nesting dolls (a set of wooden dolls that were seriated in size and fit one inside the other) and play dough. Past work has shown that middle-class U.S. parents and others with similar schooling experiences appear to place a greater emphasis on explicit, declarative statements, in contrast to tacit,

Guided Participation

procedural, and more subtle forms of verbal and non-verbal instruction which are more evident in other cultures.

These differences were evident in a comparison of the mother-child pairs Rogoff and her colleagues studied. They describe a 20-month-old and mother from both communities. Both were first-born boys who played with the nesting dolls in a skilled and interested manner. Both included a counting routine as they interacted with their mothers. For both communities, the interaction was extreme in similar ways: Counting routines are not usual with this toy in either community, and both mothers seemed more concerned with their children's performance than other mothers from their communities. As Rogoff and colleagues (1993) note, the most extreme differences between these two dyads concerned status roles. The American mother would get on the child's level, playing with or teaching her child. The Mayan mother also assisted the child but maintained a difference of status. They also differed in responsiveness and in the subtlety of their verbal and non-verbal communication. The difference is consistent with the American child "being treated as the object of teaching and the Mayan child being responsible for learning" (Rogoff, 1993, p. 246). The researchers comment that Mayan mothers showed readiness to aid in their children's efforts to learn whereas the American caregivers acted as teachers and playmates (see Rogoff et al., 1993, pp. 246-247 for full examples).

EXAMPLES OF INSTRUCTIONAL APPLICATIONS

Guided participation is most evident in interactions involving an adult or other skilled individual with an individual child or a small group of children. Examples can be found across a variety of areas including some early childhood programs (Golbeck, 2001). Detailed discussion for programs in specific practices include *Tools of the Mind* (Bodrova & Leong, 1996), one museum-based science education project (Gelman, Massey & McManus, 1991), several mathematics programs (e.g., Lampert, Rittenhouse & Crumbaugh, 1996; Cobb, Wood & Yackel, 1993), and a technique called reciprocal teaching (Palinscar, Brown & Campione, 1993) which has been used in early reading instruction and elsewhere.

In their discussion of *Tools of the Mind* (an early childhood curriculum), Bodrova and Leong (1996) identify the "structuring of situations" as an illustration. The teacher (or other adult expert) structures tasks into different levels or sub-goals. Sub-goals are broken down further or changed as the child and adult are engaged in interaction or in exploring the zone of proximal development. Guided participation occurs as the adult and child

work together on a problem. The expert may repeat directions or model actions several times. If the teacher is teaching counting, she may limit the number of objects to count or choose objects of only one type to help simplify or structure the task. When the child cannot count ten objects the teacher may drop back to counting only five objects. Such structuring helps the child perform at the highest level of the zone of proximal development. The changes the teacher makes cannot be fully planned ahead of time. They occur in response to the child and the assistance the child needs at a particular point in time.

A CLASSROOM ILLUSTRATION

The following is an example of a guided participation approach to teaching within the context of a preschool classroom. Four children and their teacher are sitting at a table in the writing center. They are working together on a book for a child in the class who is in the hospital. Every child will contribute a page and then the pages will be bound together. The children differ in age, previous writing experience, language development, vocabulary knowledge, and fine motor capabilities. The teacher has helped the children individually define writing goals, and the children have told the group of their writing plans. Because the teacher knows each child's independent capabilities she knows how she might extend their writing and help them reach their optimal performance. These children all know one another quite well and they look to one another for help, at least occasionally. The most accomplished writer is proud to help others in this context.

As the teacher chats with the children she is attending closely to their work. One child consistently fails to allow enough room on the paper for his writing. She makes a mark on his paper and suggests he start at that point. She points to the left edge of the paper, near the mark, and says that if he starts near this side he will have plenty of space to write. Another child is a much more sophisticated writer than the others. He requests help spelling. The teacher tells herself she must get a dictionary within reach of the writing center. Another child is frustrated with the writing process. The teacher was about to suggest he make a drawing to illustrate his written message, planning to have him return to the writing after he completes a drawing. But before she got the words out, another child turned to him expressing interest in his work and asked him what he was writing to their friend in the hospital. The frustrated child calmed down and said he was writing about the new truck in the block area. He returned to writing the word "truck" which he was copying from an index card written earlier by the teacher.

One more child is sitting on the teacher's lap. This child is developmentally delayed and functions at the cognitive and emotional level of a toddler. This child has had far less writing experience than the other children. He watches the others. Then the teacher hands him the crayon and they make eye contact. She points to a paper she has placed within his reach, and he drags his crayon across the paper in a slow, careful scribble. He smiles and looks at the teacher. She smiles warmly and says, "We will put this in the book too."

In this example, the teacher is working with the children to create opportunities for guided participation in different ways and at different levels of proximity to the children. She has organized the environment and has helped children identify a broad goal (making the book). This is an important and meaningful activity. She helps individual children define goals for themselves within this larger task. She has arranged the writing center with appropriate materials and brought together a small group of children, creating a social environment of peers as well as herself. She is reaching out beyond the classroom and school world with this activity by reminding the children about their classmate's situation. (They will talk more about the hospital and what it is like to be in the hospital later in the day.) The teacher is also individualizing guidance by sitting at the table watching the children's activity, coaching them as needed and keeping notes on their progress.

HELP-SEEKING

Students commonly seek help in classrooms and elsewhere when they have difficulty learning new material or completing assignments. They ask questions of teachers during whole group activity, of peers when working in small groups, and of family members when completing homework assignments. The help-seeking process in instructional contexts involves cognitive and emotional challenges that are most often public and that arise from the need for students to constantly learn more difficult curricular material. Thus it is important to understand the process and the factors that influence whether students ask for help, as well as responses to such requests, which can determine whether students continue to struggle or ultimately succeed. The explication of help-seeking begins with drawing critical distinctions between seeking help in ways considered more versus less adaptive. The term adaptive help-seeking refers to an action, namely, requesting assistance that both increases the likelihood of immediate success, such as solving a math problem, and that decreases the need for help subsequently (e.g., by learning now to solve such problems). Adaptive help-seeking also can provide short-term stress reduction and the long-term development of healthy self-system resources, such as self-efficacy, self-reliance, and perceived control, which are important for coping with future academic difficulties (Skinner & Zimmer-Gembeck, 2007).

Resources required for adaptive help-seeking (also described as instrumental, strategic, or autonomous; Butler, 1998; Karabenick, 1998; Newman, 2000) include:

1. cognitive competencies knowing when help is necessary and knowing how to formulate linguistically a specific question that yields exactly what is needed;
2. social competencies knowing which instructors and classmates are more knowledgeable and can potentially help them and knowing how and when to approach helpers and how and when to thank them;
3. affective-motivational resources academic and social goals, self-beliefs, and emotions that allow the student to tolerate difficulty and uncertainty and the ego strength required to withstand possibly negative perceptions in the eyes of classmates; and
4. contextual and interpersonal resources classroom and home affordances such as teachers' goals, grading system, collaborative activities, rules of student-teacher engagement, and teachers' and parents' expectations for the student that support the student's cognitive and social competencies and affective-motivational resources.

Help-seeking can also be viewed as a social strategy of self-regulation that is part of the resources of cognitively, behaviorally, and emotionally engaged learners (e.g., Butler, 1998; Karabenick, 2003, 2004; Karabenick & Knapp, 1991; Karabenick & Newman, 2006; Nelson-Le Gall & Resnick, 1998; Newman, 2000). Any learning strategy or tool can be used more or less effectively. Less adaptive help-seeking (also described as expedient, excessive, or executive) is

characterized as effort-avoidant and unnecessary (Nelson-Le Gall & Resnick, 1998); students requesting this sort of assistance typically put forth little effort, ask for help immediately or, for example, want others to supply the answers just before their homework is due. Because learning is not the objective, this form of help-seeking can encourage dependency. Just as seeking help that is excessive may not be in students' long-term best interests, avoiding seeking help when that help is truly necessary also can be non-adaptive (Marchand & Skinner, 2007). The distinction between more and less strategic, or adaptive, forms of help-seeking must be kept in mind when a teacher examines the personal characteristics and features of the learning context that influence its use

FACTORS THAT INFLUENCE THE INCIDENCE AND FORMS OF HELP SEEKING

Help-seeking has been extensively examined through the lens of achievement goal theory, which distinguishes between mastery-focused and performance-focused approaches to learning (Butler, 1998; Butler & Neuman, 1995; Karabenick, 2003, 2004; Pintrich, 2000; Ryan, Hicks, & Midgley, 1997). Consistently, mastery-oriented students, whose goal is to develop competence, are more likely to seek adaptive help or to work independently when that would be more effective (Butler, 1998). Performance-oriented students, who are concerned about appearing incompetent, are less likely to seek adaptive help. If such students do seek help, it is often for expedient or executive reasons to avoid work rather than to learn and improve (e.g., Karabenick, 2004).

Students' achievement goals at any point in time are a function both of past experiences and features of the contemporaneous learning context. Achievement goal structure refers to how students construe their classrooms and courses of study in terms of the contextual emphasis on mastery and/or performance goals (Midgley, 2002). Studies using hierarchical modeling have consistently found that students' perceptions of their classes' achievement goal structure influence their tendencies to seek or to avoid seeking help (Midgley, 2002). In elementary school classes, which students collectively judge as more focused on mastery, students are less likely to avoid seeking needed help (Turner, Midgley, Meyer, Gheen, Anderman, Kang, et al., 2002). Although young children are concerned about not appearing incompetent by asking for help, not until middle school do such concerns influence whether they will make a request (Newman, 2000). Presumably as a consequence of increased evaluation pressures that begin with the transition to middle school, performance goal-related classroom characteristics, in addition to perceived classroom mastery goals, affect middle school students' tendencies to seek or to avoid

seeking help (Ryan, Gheen, & Midgley, 1998). By the time students are in college, evidence suggests that classroom performance goals are more relevant than are mastery goals. Students in classes with a focus on performance-avoid goals, in which students are more concerned about not looking incompetent, are likely not to seek needed help; or, if they do seek help, they are likely to be motivated by expedient reasons (Karabenick, 2004).

Cultural factors, in particular, the degree of stress on individualism versus collectivism (Triandis, 1994) can also influence whether and in what situations students seek help. Learners in the United States especially are socialized to idealize individualism and deplore dependency (Fischer & Torney, 1976), values that typically add to the threat posed by help-seeking. In early theories of achievement motivation, seeking help was considered incompatible with individualistic values and, more specifically, an achievement motive (Nelson-Le Gall & Resnick, 1998). Learners in collectivist societies presumably are not as subject to the same prohibitions and should accordingly be less reluctant to seek help. This prediction was verified in that students raised in collectivistic-oriented Israeli kibbutz cultures were more likely to seek help than those socialized in individualistic-oriented cities (Nadler, 1998). Such cultural influences extend to learning and performance in the workplace as well. Evidence indicates that collectivistic (as opposed to individualistic) norms facilitate help-seeking due to the perceived safety that results from collectivist organizational norms (Sandoval & Lee, 2006).

When teachers examine the effects of culture on help-seeking, however, it is important for them to avoid essentialist generalizations. Doing so entails taking into consideration specific characteristics of tasks and learning contexts, such as whether the help is sought in public (as in classrooms), in relative privacy (after class or in faculty offices), or in complete privacy (e.g., delivered by a computer) (Karabenick & Knapp, 1988a). Thus, the cultural differences found by Nadler (1998) depended on whether students worked on tasks individually or in groups. In another example, Japanese collectivistic acculturation stresses cooperation, dependency, and empathy, which facilitate college students' seeking assistance from peers outside the classroom. Due to culturally induced deference to authority in the form of relationships with instructors, however, college students are hesitant to ask their instructors questions in class (Shwalb & Sukemune, 1998). Situational influences have also been demonstrated with U.S. and Australian college students. According to Volet and Karabenick (2006), the more that students are culturally different from their peers, the less likely they are to approach them for needed academic assistance. Importantly, this cultural effect was moderated by classroom factors: The negative relation between

cultural difference and help-seeking was less strong when instructors supported intercultural interaction among the students in their classes. This is but one way in which teachers can promote help-seeking in culturally diverse settings.

FOSTERING ADAPTIVE HELP SEEKING IN THE CLASSROOM

Help-seeking in the classroom is a social transaction (Newman, 1998a). Teachers establish and students internalize patterns of classroom discourse. It has been argued that teachers who respond to requests for help with hints and contingent instruction rather than direct and controlling answers help students both to accomplish difficult tasks and to learn that questioning is an invaluable academic strategy. In contrast, teachers who take on the role of expert (e.g., who present to the class an explanation without discussion and then expect students simply to practice) are likely to support overly dependent executive/expedient help-seeking. Moreover, when teachers personally demonstrate that uncertainty can be tolerated and perhaps even transformed into intellectual challenge students are likely to realize it is normal not to be able to solve all problems independently. It is expected that when teachers scaffold learning experiences and socialize the normalcy of academic difficulty, need for collaboration, and expectation of answers to their questions, students internalize a personal sense of empowerment and voice (Nelson-Le Gall & Resnick, 1998).

Ideally, students learn in their classrooms the value, usefulness, and skills of questioning that are important for monitoring, diagnosing, and fixing misconceptions. The frequency with which teachers call on students, the amount of time they wait for a response, and the amount and type of praise they give vary from student to student (Eccles & Wigfield, 1985). Teacher feedback helps students know when they need help. Giving no more assistance than is necessary may help students learn the difference between adaptive and non-adaptive (i.e., expedient) help-seeking. Encouraging students to go back to an incorrect problem and try to re-solve it may convince them of the importance of determining if they need further assistance. Additionally, it may be instrumental in students' coming to appreciate the function of questioning and help-seeking in the ongoing process of self-monitoring and learning (Newman, 1998a).

ESTABLISHING CLASSROOM GOALS

Teachers are responsible for establishing classroom goals. When both classroom and personal goals emphasize learning and developing competence, students are especially likely to

seek help adaptively, whereas when both types of goals emphasize performance, students are reluctant to do so. When students who are concerned about grades and looking smart are placed in a learning-goal classroom, they may tend to overcome and compensate for their personal tendencies to avoid help. Thus, by being attuned to individual students' personal goals, teachers can assist those who otherwise might give up in the face of adversity (Newman, 1998b). Teachers can also try to accommodate students' social goals (e.g., social affiliation, social status) that influence help-seeking (Ryan et al., 1997). The task of goal-coordinator is not easy, as multiple personal and classroom goals can complement or conflict with one another. Circumstances become even more complex when one considers that teachers' approaches to teaching, in terms of their own achievement goals, can influence how supportive they are perceived to be by students (Butler, 2007). Responsive teachers try to support student autonomy while at the same time satisfying their own personal achievement-related and social goals and need for autonomy within the constraints of public school settings (Butler, 2006).

In classrooms in which teachers share with children their time, energy, and nurturance, students tend to be attentive, effortful, self-expressive, and interested in learning. Teachers who are interpersonally involved with students and attuned to their goals typically establish classrooms that facilitate adaptive help-seeking. When teachers and students are aligned, teachers are especially able to take the student's perspective and understand his or her thinking regarding academic tasks and, based on this understanding, appropriately guide the student's learning. Teachers who are perceived as friendly and caring tend to demonstrate democratic interaction styles, with lines of communication open to students; they listen, ask questions, inquire if students need help, make sure students understand difficult material, and provide help in a non-threatening way (Wentzel, 1997). When they experience this type of communication, students learn that teachers are trustworthy helpers. Low achievers, who often have poor self-perceptions of ability and low self-esteem, typically are reluctant to seek academic help in class (Karabenick & Knapp, 1988b, 1991). For these students, especially, teachers who believe their responsibility is to attend to students' social and emotional as well as academic needs can counter student disengagement (Ryan et al., 1998).

POSITIVE AND NEGATIVE TEACHER INVOLVEMENT

Teacher involvement forms the basis of students' beliefs and feelings about the benefits and costs of help-seeking. Early elementary-age students generally feel comfortable approaching their teacher for assistance because of global,

affective traits of the teacher such as niceness and kindness. By the middle of elementary school, students tend to view teachers as helpful when they show an awareness of their problems and give them advice, time, energy, and encouragement to ask questions in class (Newman & Schwager, 1993). In classes in which teachers are perceived as supporting collaboration, student questioning, teacher fairness, respect and caring, middle and high school students are especially likely to seek adaptive help. The same is true at the college level (Karabenick & Sharma, 1994). Just as positive teacher involvement can foster help-seeking, negative involvement can do just the opposite. As early as grade 2, students often are fearful of teachers' negative reactions (e.g., "I think she might think I'm dumb") if they ask for help (Newman & Goldin, 1990). Perceived costs are heightened when teachers are unwilling to help (e.g., "if you had paid attention, you wouldn't need to ask that question"). Children weigh relative benefits and costs of help-seeking, with the integration process becoming increasingly complex over the school years, whereas older students increasingly struggle in deciding what to do when they need academic assistance (Newman, 1990).

In sum, a critically important task for teachers is to help students become self-regulated learners. Clearly, students must learn how to cope with academic difficulty. Teachers can enhance students' personal beliefs about the usefulness of help-seeking as a strategy of self-regulated learning. As noted earlier, when teachers stress the intrinsic value of learning in their classrooms and emphasize understanding and improvement rather than just getting good grades or avoiding bad grades, students are most likely to seek help in an adaptive way. Sensitive and responsive teachers buffer students from factors, such as potential embarrassment, that typically inhibit them from seeking the help they need. How teachers coordinate multiple forms of achievement and social goals, how they accommodate students' personal and interpersonal needs, how they structure task activity, and how they actually engage students through instruction can affect help-seeking and maximize the likelihood of student success.

HIGH SCHOOL, TRANSITION TO

SEE *School Transitions: High School*.

HIGH STAKES TESTING

High stakes testing is so named because the test outcomes are used to make important, often life-altering decisions. Such decisions may include the denial of a high school diploma, the repetition of a grade, the labeling of students and schools in pejorative ways, the withholding of funding, and even the closing of a school. Students who may do well in school all year but fail a high stakes test may be required to attend summer school and take the test again or spend another year in the same grade. Local newspapers routinely publish the results of high stakes tests, which can cause a range of reactions from pride to shame among students, school staffs, and parents.

ORIGINS

High stakes testing in schools had its origin in the 1980s with the publication of *A Nation at Risk* (National Commission on Excellence in Education, 1983) issued by the Reagan administration. The report stated that public schools in the United States lacked rigorous standards and were failing. It also attacked the social promotion of students. The Business Roundtable (BRT) initiated a campaign to return curriculum to the so-called basics (such as phonics), require schools to meet high standards, and be held accountable. These reforms were to be guided by experts from the business world who understood the economy (Johnson, Johnson, Farenga, & Ness, 2008).

When the Louisiana state legislature appointed a School Accountability Advisory Committee in 1998, the state became the first in the nation to inaugurate high stakes testing with harsh consequences. Fourth- and eighth-graders were targeted for testing, and students who did not score at predetermined performance levels were to spend another year in the same grade. Low performing schools were to be sanctioned with increasingly severe measures. Within a few years, 7 states based grade promotion on a statewide test score, and by 2008, 24 states were anticipated to require passing a statewide test to graduate from high school (Education Week, 2006). Additional consequences of test results include monetary rewards to high-test-performing schools in 16 states; turning allegedly failing schools over to private managers in 14 states; sanctioning, with varying penalties, low-performing schools in 28 states; and allowing closure of low-performing schools in 10 states (Johnson & Johnson, 2006).

Public Law 107-110, called the No Child Left Behind (NCLB) bill, was signed into law on January 8, 2002, by President George W. Bush. All children, regardless of physical or mental challenges, race, socioeconomic status, or English language proficiency are to have an equal and significant opportunity to attain a high-quality public education. NCLB mandates the annual testing using each state's achievement test of every child in grades three through eight. The law requires that by 2014, every child

must achieve proficiency in reading and math as measured by the high stakes tests, but it leaves the definition of proficiency to each state. NCLB links standardized test performance to sanctions for public schools that fail to make adequate yearly progress (AYP) by each subgroup of students based on special needs, minority status, English language proficiency, and socioeconomic status. Sanctions include the requirement that every school make public the achievement scores of each student subgroup. Schools that do not achieve AYP must help their students, who wish to do so, transfer to another school and pay the students' transportation costs. Schools are required to provide special tutoring for low-performing students, typically done through contracts with private tutoring firms. In extreme cases, sanctions may call for the replacement of an entire school staff (Schrag, 2007). No Child Left Behind has become synonymous with high stakes testing even though other elements of the law focus on teacher qualifications and professional development.

ARGUMENTS OF HIGH STAKES TESTING PROPONENTS

High stakes testing, as exemplified by NCLB, is highly controversial. Proponents of NCLB claim that the law has focused a spotlight on the plight of underserved, mostly minority, high poverty students. Holding schools accountable for all children, pinpointing failing schools, and allowing poor children to have access to amenities such as private tutoring, is sensible and just. The testing allows teachers to discuss low-performing students and subgroups and generate instructional improvements (Gunning, 2008). Proponents of high stakes testing believe that high standards and high stakes tests are essential to motivate students, teachers, and administrators to work ever harder to boost achievement. High stakes testing, proponents believe, will ensure that high school graduates will have the academic skills requisite for success in the workplace. For high stakes testing to be effective, the consequences of low achievement must be severe—hence, the use of sanctions such as repeating a grade, withholding a high school diploma, or school closure.

ARGUMENTS OF HIGH STAKES TESTING CRITICS

Critics of high stakes testing contend that NCLB mandates for proficiency in reading and mathematics have meant the de-emphasis or elimination of art, music, oral language, history, science, physical education, and even recess in many public schools, especially in low-performing, underserved schools. Creativity, innovation, critical thinking, discussion, and debate are things of the past in these schools, having been replaced by lock-step, repetitive test-preparation activities. The Center for Education Policy

(Dillon, 2006) reports that 70% of the nation's school districts have eliminated courses to make more time for math and reading.

High stakes test opponents argue that test scores are more likely related to socioeconomic status than to school test preparation. Standardized tests punish poor, minority, special education, and non-English-speaking students in underfunded schools who must compete with middle class and wealthy students in well-funded schools on the same high stakes tests. Children who never have traveled, have few books and resources in their homes, are hungry, ill-clad, in pain or in poor health, and who live with violence cannot be expected to make the same progress or be at the same test level as children whose life circumstances are the opposite. With high stakes testing, less privileged students must endure unwarranted stress and humiliation while being denied a well-rounded education such as that enjoyed by students in affluent or private schools (Johnson et al., 2008).

Measurement issues have been another cause for concern about high stakes testing. Group standardized tests inaccurately assess individual strengths and weaknesses, and the results are unreliable. Flaws in test design and scoring have created serious problems and have led to the recall of test results in Massachusetts, Nevada, and Georgia. A scoring error on PRAXIS, a teacher certification exam, failed 4,100 prospective teachers nationwide (Johnson & Johnson, 2006).

There is ample evidence that what is measured on state high stakes tests often does not transfer to other measurements or situations (Amrein & Berliner, 2002). Learning that does not transfer from one situation to another frequently is shallow learning.

A comparison of percentages of students achieving proficiency on state tests with the federally administered National Assessment of Educational Progress (NAEP) shows wide disparities by state. On the Mississippi state test, nearly 90% of test takers were judged proficient, but on the NAEP, fewer than 20% were shown to be proficient. In Missouri, the gap between the state and NAEP results was only 2% (Wallis & Steptoe, 2007). Such disparities illuminate the lack of transfer but also the variability in state standards and state test expectations.

Lower state standards and lower target scores to determine proficiency give the appearance that a state is doing well. In 2005, 19 states reported that 80% or more test takers scored at the proficient level on the state tests. In contrast, in only one state, Massachusetts, did more than 40% of test takers score at the proficiency level on the NAEP. Critics question what proficiency under NCLB really means. High stakes testing is corrupting American education according to Berliner and Nichols (2007), who provide examples of administrators and teachers cheating by falsifying test data.

When school staffs' reputations, salaries, and job retention are related to student test performance, such corruption sometimes happens.

Other criticisms of high stakes testing and NCLB include the increasing numbers of school dropouts as schools focus on the middle range of students to the neglect of the lowest performers (Viadero, 2007). High stakes testing has been pushed on ever younger children, including preschoolers and, under the Bush administration, Head Start children. State and federal mandated testing has led to a financial bonanza for corporations in the testing, tutoring, and publishing industries as billions of dollars are spent to raise test scores.

High stakes testing has prompted extraordinary practices. In Florida, where test secrecy is sacrosanct, a 12-year-old who gained access to a test was charged with a felony (*Education Week*, 2004). In Louisiana a multiple-district pep rally for the state test included 800 band members, 400 cheerleaders, and a flyover by Navy pilots (Nelson, 2003). The New York City school district inaugurated a plan to pay students up to \$500 for doing well on mandated tests (Medina, 2007).

While proponents and opponents of high stakes testing do battle with each other, the testing continues, and as of 2008, No Child Left Behind remains the law of the land. Only time will tell if the education pendulum swings away from the standards, testing, and accountability movement.

HOME-SCHOOL DISSONANCE

Students experience home-school dissonance when their integrity and adequacy are threatened by real or perceived differences between home/self and what is valued within the school context. Home-school dissonance includes both cognitive and affective components. It incorporates an awareness of real or perceived discrepancies between home culture—a reflection of who one is and what is valued in the school context and the negative emotional reaction that accompanies this awareness (Kumar, 2006). Phelan and colleagues (Phelan, Davidson, & Yu, 1998) defined these discrepancies as borders between students' selves—thoughts, feelings and adaptation strategies—and the worlds of home, school, and peers, all located within students' larger community. Each "world" is characterized by values, beliefs, expectations, actions, and emotional responses that may be consonant or dissonant across contexts. Not all differences necessarily lead to feelings of conflict and dissonance. It is the threat to self posed by perceived cultural differences and discrepancies, not the differences *per se* that arouses dissonance.

ANTECEDENTS OF HOME SCHOOL DISSONANCE

Home-school dissonance is often a consequence of contact between the school culture, reflecting mainstream culture, and home or community culture. Dissonance results from the differing demands placed on students as they negotiate the norms, values, and behavior expectations of both contexts (Kumar, 2006; Phelan, Davidson, & Yu, 1998). Many immigrant and minority children, and adolescents from ethnically and economically diverse backgrounds, perceive differences between home and school cultures as insurmountable (Suarez-Orosco & Suarez-Orosco, 2002). Others may negotiate the boundaries between the two even when norms, values, and behavior expectations are dissonant—though this may come at great psychological cost (Gibson, 1991; Arunkumar, Midgley, & Urdan, 1999; Phelan, Davidson, & Yu, 1998).

Adolescents' feeling of home-school dissonance is a function of the degree of polarization in values and normative expectations between contexts (Ward, Bochner, & Furham, 2001). Adolescents' subjective culture including, among others, beliefs about parents' academic and behavioral expectations, occupational aspirations, and normative attributions for school success and failure shapes their behavioral choices and motivational orientation toward learning and achievement. Immigrant and minority adolescents may find such choices problematic when family culture does not align with what is considered normative in mainstream culture.

Home-school dissonance often arises because adolescents feel that qualities they possess are devalued in school and society (Graham & Hudley, 2005). For example, the cultural markers associated with African American youth dress, music, and language are often equated with poor performance (Ladson-Billings, 1995) and classroom misbehavior (Spencer, 1999). Along similar lines, several European countries look upon *hijab* (head scarves worn by Muslim girls and women) with disfavor and preclude students from wearing *hijab* in schools. Sometimes students belonging to groups that are numerical minorities in school or whose phenotypic characteristics differ from mainstream society feel marginalized because they do not "fit in" with peers and others (Brewer, 2003).

By studying acculturation patterns of immigrant minorities to host societies, researchers highlight the importance of intercultural relations within the school context to understand adolescents' experiences of home-school dissonance (Montreuil & Bourhis, 2004). Group membership is the lens through which individuals in a culturally pluralistic society view one another. Thus when students categorize themselves as minority or others within the school context, the probability of stereotyping, ethnocentrism, intergroup clashes, and competition increases (Tajfel & Turner, 1979). Mainstream members are more likely to adopt a segregationist orientation toward immigrants whose culture differs considerably from the mainstream. Ethnic group relations in schools parallel ethnic and minority immigrant group inclusion or exclusion within American society (Montreuil & Bourhis, 2004). In fact, cultural minority students in more integrated school environments report greater exclusion and ostracism than students in more homogenous school environments. Friendship patterns in schools are also based on the inclusion or exclusion of a student's racial, ethnic, or national group.

While some experiences of home-school dissonance are tied closely to students' racial, ethnic, religious, and socioeconomic background, others cut across cultural lines. Students often feel marginalized when not performing well in school and when they feel disengaged from an environment designed to promote learning (Kumar, Gheen, & Kaplan,

2002). Kumar (2006) conducted a growth-curve study examining stability and change in adolescents' experiences of home-school dissonance during the elementary-to-middle school transition and found that dissonance increases when students perceive an evaluative classroom environment and move into middle schools that encourage social comparison and competition among students. These findings are supported by interviews conducted with seventh-grade students who reported high home-school dissonance. No two students experienced dissonance for all the same reasons. Interviews indicated that lack of material resources and cultural affiliations promoted feelings of dissonance in many students. Additionally, students described school factors, including emphasis on relative ability in the classroom and the nature of student-teacher relationships, as contributing to home-school dissonance.

Beliefs and behaviors of significant others in both contexts may also trigger feelings of home-school dissonance among students. Teachers' attitudes toward students, together with the ways they communicate expectations, influence students' beliefs about themselves, motivations and behaviors (Oakes, 1985). Evidence indicates that teachers reflect society's deep ambivalence toward minority and immigrant students in their attitudes towards these students (Suarez-Orosco & Suarez-Orosco, 2002). If teachers view cultural minority students as lazy, less intelligent, and more prone to trouble, such expectations may exert a profound effect on students' beliefs about school, motivation and behavior thereby exacerbating feelings of dissonance.

PSYCHOLOGICAL CONSEQUENCES OF HOME SCHOOL DISSONANCE

There is a psychological cost associated with feeling caught between two cultures, marginalized, powerless, and socially alienated (Rosenberg, 1962; Ward, Bochner, & Furham, 2001). High-dissonance fifth-grade students reported feeling angrier, engaged in more self-deprecation, had lower self-esteem, were less hopeful about the future, felt less academically efficacious, and had a lower GPA than low-dissonance students. Additionally, high-dissonance students experienced a greater decline in GPA and smaller decline in anger than low-dissonance students when moving from elementary school to the larger, more complex middle-school environment (Arunkumar et al., 1999). Home-school dissonance, controlling for ethnicity, is also a significant predictor of skeptical beliefs about the value of school (Kumar, Gheen, & Kaplan, 2002) and lower levels of school belonging (Kumar, 2006). Poor intercultural adjustment is associated with depression, anxiety, and poor emotion regulation among students of different ages (Buddington, 2002).

For some adolescents and young adults from immigrant and minority groups the sociocultural differences between classroom and family culture norms interfere with their ability to adjust to school environments (Lafromboise, Hardin, Coleman, & Gerton, 1993). Tharp and his colleagues (Vogt, Jordan, & Tharp, 1993) demonstrated that traditional American classroom structure (independent seat work, whole-class instruction) interfered with Hawaiian students' learning. Changes in classroom structure that incorporated group learning centers and peer collaboration similar to their community's emphasis on sharing, cooperation, and group needs facilitated adjustment to school. Gibson's ethnography (1991) demonstrated that Punjabi adolescents not joining majority-dominated school activities were made to feel culturally inferior by their peers. Ogbu (1987) attributes poor school performance, low motivation, and high dropout rate among African Americans and non-immigrant Latinos as resistance to mainstream institutions. Research also indicates that the aggressive coping attitude of African American youth results from the dilemma posed by competing allegiances and socialization contexts that are daily stressors. This reactive coping mechanism is seen as a response to negative peer and teacher perceptions and an inferred, undervalued sense of self (Spencer, 1999).

Both negative and positive stereotyping regarding group intellectual capacity contribute to dissonance. Experimental studies on stereotype threat demonstrate that awareness of negative stereotypes regarding one's groups' intellectual capacity results in disidentification with academic achievement (Steele 1997) and dropping out of school (Osborne & Walker, 2006), because group members perceive these attributes as stable, internal, and uncontrollable (Reyna, 2000). It is equally likely that the "model minority" stereotype associated with Asian American adolescents often sets them up for failure. Many low-performing, model-minority adolescents feel ashamed of poor performance and inability to fulfill the stereotype. Consequently, they are reluctant to seek academic support, thereby perpetuating their academic struggles (Lee, 1996).

AMELIORATING DISSONANCE IN SCHOOL AND CLASSROOM PRACTICES

Schools and teachers who want to promote the well-being of students at risk for experiencing dissonance need to face the challenge of minimizing the saliency of differences among students and work to foster learning within an inclusive and empowering environment. This can be accomplished at the individual level by requiring teachers and school personnel to examine their own beliefs and behaviors toward culturally diverse students and at the systems level by restructuring school practices in ways that help ameliorate home-school dissonance.

For quite some time educators have stressed the need to encourage teachers to critically examine, and overcome their personal prejudices and biases so that they may be fair and equitable in their dealings with students. As early as 1971 Geneva Gay, a prominent multicultural education scholar, developed a model for educating prospective teachers. The model included three components for multicultural education: *knowledge*, whereby "teachers become literate about ethnic group experiences" (p. 34); *attitudes* "to help teachers examine their existing attitudes and feelings towards ethnic, racial, and cultural differences" (p. 43); and *skills* "to translate their knowledge and sensitivities into school programs, curricular designs, and classroom instructional practices" (p. 48). The 2006 revisions of the National Council for Accreditation of Teacher Education (NCATE) guidelines advocate the deliberate articulation of multicultural values into all the standards that define quality teaching; a focus on the ideals of fairness; the utilization of teaching and learning strategies that permit all students to learn; and the application of knowledge as it relates to students, families, and communities.

The social reconstructionist view of multicultural education takes a systems approach and calls for major school policy reform that will promote equity among students (Banks & Banks, 1997). It urges schools to dismantle policies and practices promoting inequality such as tracking and ability grouping and replace them with policies and practices that empower students to acquire the knowledge and skills necessary to function effectively. This, according to Banks & Banks (1997), requires integration of multicultural curricula into all subject areas; an understanding among teachers that all knowledge is culturally constructed (and thus necessitates the adoption of culturally relevant pedagogical approaches); and the reduction of prejudice and improvement of inter-group relationships in the learning context. In essence, social reconstructionists' vision of education through equity pedagogy and culturally responsive teaching requires redefinition of school culture that students find empowering, validating, and inclusive.

The understanding of school and classroom culture in a way that can help ameliorate home-school dissonance and foster a sense of belonging to school, can be advanced by achievement goal theory, a social cognitive theory of motivation that conceptualizes the relationships between school learning environments and students' motivational, emotional, and academic well-being. Achievement goal theory defines school practices that encourage intellectual development through effort and engagement in challenging activities as "mastery-focused," and describe school practices in which comparison and competition are the norm as "performance-focused" (Maehr & Midgley, 1996). For instance, practices such as public honor rolls or special privileges based upon academic standing send

important messages to students regarding what constitutes success in a given school (Maehr & Midgley, 1996). In a performance-focused school environment, the nature of the task is not the issue; rather, the focus is on student performance, particularly relative to others. Thus, one of the main distinctions between mastery- and performance-focused environments is a focus on self-improvement versus a focus on the self in comparison to others in the environment.

Mastery-focused learning environments are designed to create a community of learners in an atmosphere of mutual respect. An environment that promotes respect for and openness toward others' ideas and ways of thinking is more likely to encourage students and teachers to be less judgmental of others whose ideas, values, and cultural norms are different from theirs. Thus, a mastery-focused academic culture, unlike a performance-focused one, is beneficial for students at risk of experiencing home-school dissonance (Kumar, 2006).

Research across disciplines indicates that home-school dissonance produces negative consequences. Though not all minority students experience home-school dissonance, they are at risk if they perceive insurmountable discrepancies between the two contexts. Nevertheless, mastery-focused school and classroom environments can be created that ameliorate feelings of home-school dissonance and emphasize differences as a source of opportunity. This is best done exposing students to multiple cultural perspectives and contrasting systems of thought and affect, thus creating cognitive flexibility and tolerance.

HOME SCHOOLING

Home schooling is a term used to refer to the education of children by their parents or guardians in a setting other than a public or private school, most often in their homes. Home schooling styles vary substantially; there is no typical home schooling day. Methods of instruction include, but are not limited to the parent directly instructing the child, the child watching a video recording or satellite feed of an actual classroom, completing self-study workbooks or computer programs, some types of online instruction, or reading literature (Clements, 2004). Additional activities may include field trips, volunteering, scouting, organized sports, or taking classes through a home school cooperative in which parents teach groups of students. There is a practice often described as unschooling in which no traditional educational activities are employed, but students are encouraged to learn through life experiences (Clements, 2004). An example might be learning geometry, physics, drawing, and economics through the planning and construction of a structure such as a cabin or small home.

THE EMERGENCE OF HOME SCHOOLING

Parents' right to direct the education of their children is founded on the Fourteenth Amendment to the U.S. Constitution as interpreted in *Pierce v. Society of Sisters*. In 1925, after the state of Oregon adopted a law requiring all children to be educated in public schools, the U.S. Supreme Court ruled in *Pierce v. Society of Sisters* that private schools have the right to exist and that parents have the right to direct the upbringing and education of their children (Bloom, 2003). This decision has been commonly used to support home schooling, as have several legal opinions since (e.g., *Troxel v. Granville*, decided June 5, 2000, as cited in Bloom, 2003).

State legislatures, influenced by repeated legal challenges from home schooling families, gradually changed their laws to permit the practice of home schooling as it grew in popularity during the 1980s. By 1993 home schooling had become legal in all 50 states in one form or another. The increased availability of home schooling as an educational option and reduced stigma toward home schooling since the 1980s partially explains its

estimated annual growth rate of 15 to 20 percent during the 1990s (Lines, 2000). As of 2003 home schoolers constituted approximately 2.2 percent of the total school-age population (National Center for Education Statistics [NCES], 2006). However, attempts to pin down the actual number of home schooled children found that 2 to 3 percent of the school-age population remained unaccounted for in either home school or traditional school reporting, so the number could actually be closer to 5 percent. Because not all states require registration of home school families, the exact number of children being home schooled is difficult to determine (Lines, 2000).

Home schoolers have traditionally been thought to consist primarily of very conservative or very liberal families. Religiosity is significantly associated with both private schooling and home schooling. Evangelical Protestant parents are more likely to home school than are other groups of parents, but do not constitute the majority of home schoolers (Isenberg, 2007). Since the rapid increase in home schooling during the 1980s and 1990s, families from many religious and political persuasions are found among those home schooling (Reich, 2002; Romanowski, 2001). The typical home schooled child comes from a two-parent household in which parents have an above-average level of education, according to the *U.S. Department of Education Trends in Schools from 1993–1999* (NCES, 2003). Compared with private school children, however, home school children tend to come from less affluent and more rural households.

PARENTS' REASONS FOR HOME SCHOOLING

After completing an empirical study investigating parents' reasons for home schooling, Green and Hoover-Dempsey stated, "Homeschool parents appear to decide to home-school not so much because they believe that public schools cannot educate their children but because they believe that they are personally responsible for their child's education and they are capable of educating their children well in ways consistent with their priorities" (2007, p. 278). According to Brian Ray (2006), president of the National Home Education Research Institute [NHERI], primary goals prompting families to home school include the following:

- Teach a particular set of values, beliefs, and worldview
- Accomplish more academically than in schools
- Customize or individualize the curriculum and learning environment for each child
- Use pedagogical approaches other than those typical in institutional schools, enhance family relationships between children and parents and among siblings

In a typical home schooling scenario, the lessons for each child are tailored to that particular child. BRIDGET BESAW GORMAN/AURORA/GETTY IMAGES.

Provide guided and reasoned social interactions with youthful peers and adults

Provide a safer environment for children and youth, given problems in schools with physical violence, drugs and alcohol, psychological abuse, and improper and unhealthy sexuality

The National Home Education Network publication *Reasons to Home School* listed spending more time together as a family as the number one reason to home school. In 1999 and 2003, the National Household Education Surveys Program (NHES) collected responses from a nationally representative sample regarding reasons people choose to home school. The top reasons were “concerns about the environment” of other schools (31%), “to provide religious or moral instruction” (30%), and “dissatisfaction with academic instruction” at other schools (16%, NCES, 2004, p. 2). Isenberg (2007), by combining several sources of data on reasons for home schooling, supported the idea that approximately 30% of parents home school primarily for religious reasons (25% to

52%, depending on the year of data collection) but that educational reasons are more often cited as reasons for home schooling. These include dissatisfaction with current public schools as well as disability or exceptionality of the child being home schooled.

Many parents who choose to home school cite a weakening of emphasis on the teaching of traditional school subjects such as writing and mathematics in public schools and a promotion of certain social constructs such as tolerance. For example, as states enact legislation that mandates teaching tolerance regarding such controversial subjects as homosexuality, parents who object to those subjects being taught to their children become more likely to remove their children from public schools. This exodus from schools, seen as many educators as sheltering children from developing a broader world view, is seen by home schooling parents as a chance to both teach children their own world view and protect their children from indoctrination with competing views.

THE EFFECTS OF HOME SCHOOLING

There is abundant evidence that home school students tend to be quite successful academically and socially. Home schoolers' average test scores have been well above that of their public and private school counterparts on average. In fact, as of 2008, no study indicated lower achievement (Lines, 2000) or poorer adjustment of home-schooled children. However, just as there is difficulty obtaining an accurate number of children being home schooled, there is difficulty ensuring the representativeness of data reporting on the effectiveness of home schooling. It is possible that those parents who are more successful at home schooling are also more likely to respond to surveys, report achievement data, have their children participate in standardized testing, and have children who apply for college admission.

Home Schooling and Achievement. In 1998 Lawrence Rudner of the University of Maryland conducted a study of 20,760 home schooled children who took the Iowa Tests of Basic Skills or the Tests of Achievement and Proficiency. Among the findings were the following:

The median scores for every subtest at every grade (most in the 70th to 80th percentile) were well above those of public and private school students.

Almost 25 percent of home school students were enrolled one or more grades above their age-level peers in public and private schools.

On average, home school students in grades 1 to 4 performed one grade level above their age-level public/private school peers.

The achievement test score gap between home school students and public/private school students widens from grade 5 upwards.

Students who have been home schooled their entire academic lives have higher scholastic achievement test scores than students who also have attended other educational institutions.

Rudner's findings are not atypical. An earlier study by Ray (1997) showed higher standardized test scores among home school students than among the general population. A separate study found that home school children in the state of Washington consistently scored above the national average in reading, language, math, and science. Of course, these are data from children who participated in these assessments. Nothing is known about children who were not tested.

In a survey of adults aged 18 to 24 who had been home schooled, more than 74 percent have taken college-level courses as compared with 46 percent for the general U.S.

population. An overwhelming majority of them report that they are glad they were home schooled (Ray, 2006). In a related study, it was found that, while the potential for success in college did not differ significantly between home school graduates and conventional-school graduates, home school students did earn higher scores on the ACT English subtest (Ensign, 1997).

Perceptions of home schoolers applying for college admission became more favorable between 1993 and 2008. As of 2004, approximately 75 percent of institutions had a home school admission policy, and the vast majority of college admissions officers responding to the survey reported that they expected home-schooled students to do as well or better than non-home schooled students. In fact, no significant differences are typically found between home schooled and traditionally schooled first-year college students on ACT score, GPA, or retention.

The home schoolers' achievements that have gained the most public attention have been spelling and geography bee wins. In 2001, the winner of the National Spelling Bee was the third winner in five years to have been home schooled. Ten percent of the 2001 spelling bee contestants were home schooled (which is significant given that home schoolers made up less than 5 percent of the student population with some estimates as low as 2 percent). In 2000, eight of the finalists had been home schooled, with home schoolers taking the top three places.

Home Schooling and Socialization. The primary concern expressed about home schooling does not involve academic achievement, but tends to be related to students' socialization or more accurately lack of socialization. Those concerned envision home schoolers as being isolated with their parents, having little cultural exposure, little opportunity to interact with other children, and having minimal contact with the world beyond their homes. In truth, for many home schoolers the opposite is true. Some have such an excess of social and extracurricular activities that having time to complete their studies can be challenging. Many, if not most home schooling parents supplement academic material with extracurricular activities such as music lessons, sports, scouting, church activities, and other endeavors that engage children with their peers (Clements, 2004).

Not only are findings about socialization of home-schooled children not negative, several researchers have found an overwhelmingly positive picture of the socialization of home school students (see, for example, Medlin, 2000). Home schoolers are provided opportunities that foster positive interaction and they also are protected from many sources of negative socialization (Lines, 2000; Romanowski, 2001; Shyers, 1992). Richard Medlin of Stetson University found that self-concept was higher for home school students than for public school students, and in a

blind, controlled study comparing 70 home school with 70 non-home school children, the former had fewer behavioral disorders (Lines, 2000).

Home Schooling and Homogenization. One goal of public education is to provide common experiences for children with the goal being some degree of homogenization of citizens. Along with fears about lack of socialization in home schoolers, an additional criticism involves an alleged lack of homogenization of home school children. Some, such as Rob Reich (2002) of Stanford University, believe that children should be exposed to a common set of ideas and have a common set of experiences. He sees a civic peril in insulating children from certain ideas. However, the same argument could be leveled against public schools. The practice of prohibiting the expression of religion in public schools particularly Christianity is an example. It is unlikely that a child whose parents have never introduced him or her to Christian beliefs would learn about them in public school. The argument for exposing the child to a broad range of ideas thus breaks down. Reich goes on to argue that children should learn decency, civility, and respect. However, the perceived absence of these values in the public school environment is a common reason that parents remove their children from public schools in favor of home schooling.

Some Explanations for the Success of Home Schooling. Available data suggest a number of hypotheses as to why home-schooled children excel academically. These include parental involvement, the education level of the parents, and the benefits of one-on-one instruction. Romanowski of Ohio Northern University and Hoxby of Harvard, among others, attribute home schooled students' success to the high degree of parental involvement. There has been a great deal of research supporting the benefits of parental involvement in children's education. In fact, teacher training programs and schools routinely recommend techniques for soliciting parents' involvement within public and private schools for this reason.

A second possible explanation for the academic success of home schoolers is that home-schooled children tend to have more educated parents (Romanowski, 2001). As mentioned, home schooling families tend to have parents with more years of education than public and private school families. Either the value placed on education or the intelligence that enabled those parents to complete more education could contribute to their children's academic success.

An additional reason for the success of home schooling is that one-on-one instruction has traditionally been thought to be more effective than traditional group schooling. In a typical home schooling scenario, a parent may teach only one or may teach multiple children, but the

lessons for each child are tailored to that child. This is of particular benefit to children who learn more rapidly or more slowly than most children in their age group. In group schooling teachers usually teach to the majority which tends to be composed of children achieving at the average rate, leaving slow learners behind and causing rapid learners to lose interest. One-on-one instruction has also been found to be beneficial to children with attention deficits. Having fewer people in the learning environment reduces distractions, thereby helping the student to stay focused on learning.

THE AVAILABILITY OF THE OPTION TO HOME SCHOOL

Research has accumulated over several decades showing numerous benefits of home schooling; however, it is not possible for all families who would like to home school their children to do so. Most, but not all, of these reasons are economic. Families who must have two incomes or families in which a single parent is the only income earner have difficulty home schooling. However, there are non-economic reasons as well. There are families in which the parent or parents do not have the education or temperament to be able to effectively home school (Clements, 2004). For these, a group schooling setting may be their only option.

HOMEWORK

Homework can be defined as tasks assigned to students by teachers that are intended to be carried out during nonschool hours. This definition excludes (a) in-school guided study (although homework is often worked on during school); (b) home study courses, and (c) extracurricular activities such as sports teams and clubs.

VARIATIONS IN HOMEWORK

According to Harris Cooper (2007), the most common variation in homework assignments relates to its content or subject matter. Independent of content, homework assignments also vary in their purpose or goal. Practice homework assignments ask students to go over material already presented in class so as to reinforce learning and facilitate mastery of specific skills. Preparation assignments introduce material that will be presented in future lessons. These assignments aim to help students obtain the maximum benefit when the new material is covered in class. Extension homework involves the transfer of previously learned skills to new situations, such as asking students to apply their mathematics knowledge to construct a household budget. Finally, integration homework requires the student to apply separately learned skills to produce a single product, such as reading a book and writing a report on it.

Homework also can serve purposes that do not relate directly to instruction. Homework can be used to (a) establish communication between parents and children, (b) fulfill directives from school administrators, (c) punish students, and (d) inform parents about what is going on in school. Most homework assignments have elements of several different purposes.

Assignments can vary in many other ways, including the skill area covered (e.g., reading, writing, math), the level of difficulty, and the time required for completion. With regard to the latter, the amount of homework students are assigned can best be thought of in terms of (a) the frequency, or how often, homework is assigned and (b) the duration of each assignment, or how long it takes to complete each assignment. For example, two students doing four hours of homework a week might be having very different homework experiences. One might be doing one hour of homework on each of four nights while the other is doing two hours of homework on just two nights.

POSITIVE AND NEGATIVE EFFECTS OF HOMEWORK

The most direct positive effect of homework is that it can improve the retention and understanding of academic material. More indirectly, homework can improve students' study skills and attitudes toward school (by showing how skills that are learned in school have application to activities students enjoy doing outside school) and can teach students that learning can take place anywhere, not just in school buildings. The nonacademic benefits of homework include fostering independent and responsible character traits. Finally, homework can involve parents in the school process, enhancing their appreciation and understanding of what goes on in the classroom and allowing them to express positive attitudes toward the value of school success.

Homework can have negative effects as well. It can lead to boredom with schoolwork if students are required to spend too much time on academic material. Homework can deny students access to leisure time and community activities that also teach important life skills. Parent involvement in homework can turn into parent interference. For example, parents can confuse their child if the instructional techniques they use at home differ from those used by teachers. Homework can lead to the acquisition of undesirable character traits if it promotes cheating, either through the copying of assignments or if the student receives help with homework that goes beyond tutoring. Finally, homework could accentuate existing social inequities. Diane Scott-Jones has argued that children from disadvantaged homes may have more difficulty completing assignments than their middle-class counterparts.

Homework can reinforce concepts taught in the classroom. ANDY SACKS/STONE/GETTY IMAGES.

RESEARCH ON HOMEWORK

Research on homework generally supports the notion that it helps students learn academic material, but with important qualifications. Cooper, Jorgianne Robinson, and Erika Patall have conducted, since 1984, six studies that used two groups of students who were on average as similar as possible by randomly assigning students to groups, statistically controlling for student differences, or matching a student in one group with a similar student in the other group while eliminating students who did not have a good match and then manipulated whether students did or did not receive homework assignments. These studies provide a clear picture that homework can be effective in improving students' scores on unit tests (the class tests that come at the end of a topic unit). Students doing homework in second grade did better on number places, third and fourth grade did better on English skills and vocabulary, fifth grade on social studies, high school on American history, and twelfth graders on Shakespeare. Across five studies, the average (50th percentile) student doing homework had a higher unit test score than 73% of students not doing homework.

A second type of study supports the conclusion that students who do homework perform better on tests. This type simply asked students (or one of the students' parents) how much homework the students did; no manipulation of homework assignments was involved. However, these studies attempted to statistically equate students on other characteristics that might be associated with homework and achievement and therefore might account for any relationship between the two. Because they do not purposely manipulate homework, these studies can never lead to as confident a conclusion about homework's direct effect on achievement. However, they do typically involve large nationally representative samples of students such as the National Educational Longitudinal Study. Also, these studies typically use broader measures of achievement than unit tests, such as cumulative grades and standardized test scores. Twelve such studies have tested more than 30 different statistical models. The other factors that might influence achievement (and time on homework) that were controlled for in the statistical models included numerous student factors (for example, sex, ethnicity, ability, motivation), family factors (for example,

wealth, parent involvement), school factors (for example, subject matter, teacher training, class size), and other student behaviors (for example, TV watching, extracurricular activities and jobs, absences from school). Achievement was measured for all sorts of content areas using all types of achievement measures. In 11 of the 12 samples, the link between time on homework and achievement was positive.

A third type of study that looked at homework involved no attempt to purposively vary homework or to equate students on other characteristics that might explain any relationship. Thus, these correlational studies can make no claims about a causal link between homework and achievement. Though not conclusive, this type of evidence can give important clues about when, where, and for whom homework might be more or less effective. In 35 samples of students used in correlational studies, 27 found the link between homework and achievement was a positive one; in 8, it was negative.

The correlational results were noticeably different depending on the grade level of the students. The average correlation between time spent on homework and achievement was substantial for secondary school students but for elementary school students, it hovered around no relationship at all. There are several possible explanations for this finding. First, cognitive psychologists Dana Plude, James Enns, and Darlene Broudeur suggest that younger children are less able to tune out distractions. It is easy to imagine that the distractions present in a younger student's home would make studying there less effective for them than for older students. Second, a study by Annette Dufresne and Akira Kobasigawa suggests that younger students have less well-developed study habits. Their study showed that older students spend more time than younger ones working on harder items. Older students were also more likely to use self-testing strategies to monitor how much of the material they have learned.

Other explanations for the weak correlation between homework and achievement in early grades are possible. A study by Laura Mulhenbruck, Cooper, Barbara Nye, and James Lindsay found evidence suggesting teachers in early grades may assign homework more often to develop young students' management of time—a skill rarely measured on standardized achievement tests or graded in class. This study also provided some evidence that young students who are struggling in school take more time to complete homework assignments. Thus, while it seems highly likely that age difference in attention span and study habits can be applied to the homework situation, it is also likely that poor-achieving young children spend more time on homework simply because it is more difficult for them.

APPROPRIATE AMOUNTS OF HOMEWORK

Based on these results and the experience of teachers, consensus has emerged regarding rough guidelines for the amount of homework that should be assigned to students in different grade levels. The National PTA and the NEA suggest that homework for children in grades K-2 is most effective when it does not exceed ten to twenty minutes each day. In grades 3 through 6, children can benefit from 30 to 60 minutes per day. Junior high and high school students can benefit from more time on homework and the amount might vary from night to night. These recommendations are consistent with the conclusions reached by studies of the effectiveness of homework.

In conclusion, homework can be an effective instructional device. However, both experience and research suggest that the relationship between homework and achievement is influenced greatly by the students' developmental level. Expectations for homework's effects, especially in the short term and in earlier grades, must be modest. Further, homework can have both positive and negative effects depending on how it is used, with whom, and in what context.

I

IDENTIFICATION WITH ACADEMICS

Identification with academics is related to the notion of domain identification introduced by William James (James, 1890/1981). James argued that every person has an almost infinite number of possible selves, but that individuals focus on a few core domains in defining the self. These core selves that a person identifies with can have a profound influence on everything from self-esteem and motivation to behavior. Other selves are regarded as unimportant. This process of placing more or less importance on certain aspects of the self is called “selective valuing.” While there has been debate on whether these ideas can be empirically validated, many researchers accept them because of their intuitive appeal.

Identification with academics is a special case of domain identification and selective valuing. It refers to the extent to which an individual defines the self through a role or performance in a particular domain, in this case schooling and academics. The concept of domain identification is rooted in the Symbolic Interactionist perspective on self-esteem, which is presented graphically in Figure 1. In general, this model states that 1) individuals get lots of feedback in many different ways almost constantly and 2) if this feedback is received and viewed as accurate/valid, it is incorporated into an individual’s domain-specific self-concept. If this part of self-concept is important, the feedback will affect self-esteem.

According to this model, outcomes in a domain will only affect an individual’s self-esteem to the extent that the individual is identified with that domain. Another characteristic of this perspective is that there are not only

individual differences in identification with a specific domain, but also changes within an individual over time in domain identification (e.g., Tesser, 1988). In other words, one person may view proficiency at tennis as a huge aspect of the self, while another could not care less about how well he or she plays tennis. Over time, as circumstances change, one’s view of how important tennis is to the self might become less or more important.

IMPORTANCE OF IDENTIFICATION WITH ACADEMICS

If having a positive self-view feels good and a negative self-view feels bad (psychologists differ on this point), it follows that healthy individuals are motivated to maintain a positive self view. They are strategic and will value those domains that are most likely to produce positive feedback for the self, and will alter their domain valuing as conditions change, all with the goal of maximizing how positive the self-view is (Steele, 1988; Tesser, 1988).

From a simple reinforcement/punishment perspective, stronger identification should be related to more positive outcomes in that domain. Individuals should be motivated to behave in ways that maximize the probability of positive outcomes (and minimize the negative outcomes) in domains they strongly identify with. For students strongly identified with academics, good academic performance should be rewarding (leading to a more positive self-view, which feels good) whereas poor academic performance should be punishing (leading to a more negative self-view, which feels bad). Similarly, students not identified with academics should have little motivation to succeed in academics because there is no link between academic outcomes and

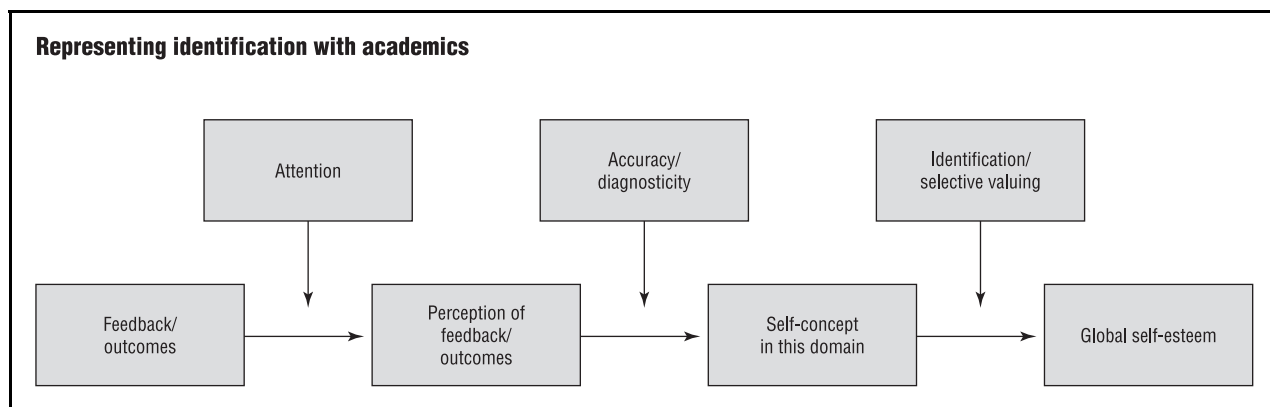

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

self-esteem good performance is not intrinsically rewarding, and poor performance is not intrinsically punishing. For these students, motivation comes from other domains outside academics.

MOTIVATION AND/OR ACADEMIC OUTCOMES

Research supports the notion that identification with academics increases the odds of success in academics (Osborne, Kellow, & Jones, 2007). Figure 2 shows the theoretical relationships between identification with academics and motivation to succeed as well as outcomes in that domain. (Other literatures, such as management and parenting literatures, have noted similar effects.)

Identification with academics predicts academic achievement (Osborne, 1997a; Osborne & Rausch, 2001; Voelkl, 1997), receiving academic honors or being put on academic probation (Osborne, 1997a), engagement in learning/classroom activities (Osborne & Rausch, 2001; Voelkl, 1997; Walker, Greene, & Mansell, 2006), stronger academic self-efficacy (Walker et al., 2006), and even academic dishonesty (K. V. Finn & Frone, 2004). These studies show that stronger identification with academics increases motivation to succeed and the amount of effort students put into learning. Given this, it should not be surprising that these students are also more likely to achieve better outcomes in academics. Importantly, identification with academics has been linked to decreased likelihood of undesirable behaviors, such as cutting class, absenteeism, and dropping out (Osborne et al., 2007).

MEASURING IDENTIFICATION WITH ACADEMICS

There is no consensus on how to measure identification with academics. Valuing, belonging, positive predispositions toward school, and behaviors that signal engagement in learning/schooling are theoretically linked to identifica-

tion with academics, but do not capture the essence of it. Some researchers (Spencer, Steele, & Quinn, 1999) have argued that students who enroll in challenging academic courses and who possess well above average standardized scores are de facto classified as identified, but there are also gifted students who do exceedingly well and then drop out as soon as they can. Additionally, this perspective ignores extrinsic motivations for doing well in school. True identification with academics is a purely intrinsic process (although it can be influenced by external forces). Others (e.g., Aronson et al., 1999) have supplemented these indicators with items that assess the relevance of the domain ("Mathematics is important to me") to students. Other researchers (Morgan & Mehta, 2004; Osborne, 1995, 1997b; Verkuyten & Thijs, 2004) have operationalized this as the relationship between measures of self-concept and academic outcomes. Referring to Figure 1, it is obvious that among students with strong identification, there should be a strong relationship between self-concept and academic outcomes. Yet this approach is severely limited in that it can only speak to large groups, although it may be important for initially establishing the validity of the general concept.

Researchers have published scales intended to measure identification with academics from the perspective presented above (Osborne, 1997a; Osborne & Walker, 2006, Voelkl, 1996, 1997, Finn, 1989). These scales are designed to assess student feelings of belonging (i.e., acceptance of and respect for the self by others in the school, feelings of inclusion) and valuing (i.e., the extent to which the student views schooling as an important institution in society, and the material being learned as important and useful).

INDIVIDUAL AND GROUP DIFFERENCES

As James and many later theorists have argued, individuals differ not only in what domains they identify with,

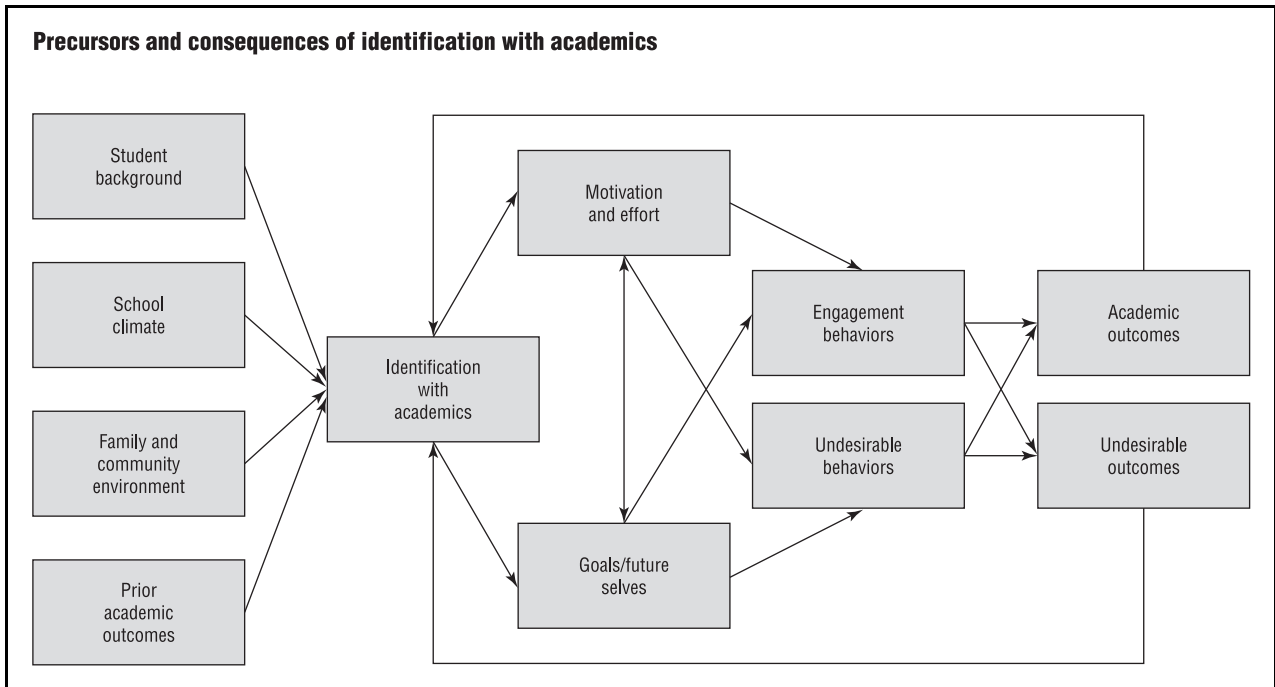

Figure 2 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

but also how complex the self is (i.e., how many domains they identify with. (For a review of self-complexity, see (Rafaeli-Mor & Steinberg, 2002.) Research strongly suggests that identification with academics is changeable, and as Finn (1989) and others argue, changes long before bad things happen academically (e.g., withdrawal from school). Therefore, there is significant hope that should students begin to disidentify, and if this change is diagnosed early enough, intervention can prevent serious consequences.

Identification with academics is also implicated in important social trends, such as the long-standing achievement gap between Caucasian students and students from disadvantaged/stigmatized groups (e.g., African American, Native American, Latino). Claude Steele's Stereotype Threat hypothesis (Steele, 1992, 1997, 1999; Steele & Aronson, 1995), for example, argues that members of academically stigmatized groups should show higher anxiety in school, and ultimately defensively disidentify with academics (see also Major & Schmader, 1998; Major, Spencer, Schmader, Wolfe, & Crocker, 1998). Research from several cultures and across many years has shown this disidentification effect predicted by Steele at the group level when comparing stigmatized and non-stigmatized groups (Cokley, 2002; Demo & Parker, 1987; Hansford & Hattie, 1982; Morgan & Mehta, 2004; Osborne, 1995, 1997b; Osborne, Major, & Crocker, 1992; Rosenberg & Simmons, 1972; Verkuyten

& Thijs, 2004). Interestingly, when stigmatized individuals (such as African American students) answer questionnaires about identification (valuing of) academics, there is often either no difference between the two groups or the African American students score higher than Caucasian Americans (e.g., Major & Schmader, 1998). On an individual level, parents, teachers, and others in power can reduce stereotype threat and/or enhance identification with academics. The literature gives many options, including (a) increasing positive outcomes, (b) promoting the importance of academic domains, (c) fostering a sense of belonging, and (d) lifting the situational threat. Those interested in this process should consult Osborne et al. (2007) for more on these strategies or Steele (1997) for other ideas specific to stereotype threat.

IDENTITY DEVELOPMENT

Identity is an individual's self definition that focuses on enduring characteristics of the self. In an established identity, the individual is able to explain the origins of these self-defined characteristics and the influences behind those origins. Complete identity includes a clarification of one's morals, ethics, and standards, as well as a commitment to a future occupation. Many development theorists see identity development as a means for an individual to explain the present as a bridge from the past to the future.

MAJOR PROCESSES IN IDENTITY DEVELOPMENT

The major processes that comprise identity development are addressed by Erik Erikson (1902-1994) in his theory of psychosocial development. Most psychologists appreciate Erikson's theory because of its "utility in many professional arenas [such as] clinical, theoretical and empirical" (McKinney, 2001).

Erikson was interested in explaining the development of the healthy personality, based on an enduring ego identity. The healthy ego identity evolves through a process of discovering the self within the various influences of a personal history, societal history, and social contexts. For Erikson this evolving of the ego identity takes place through stages of psychosocial development. In each stage, the psychological make-up of the individual interacts with the demands of the social context in a challenge that either brings about a healthy resolution or an unhealthy alternative. This age-related challenge is referred to as a crisis. Each of these crises represents a “direct reflection of the person’s social maturity and societal expectations” (McKinney, 2001). All of the psychosocial stages are interdependent; the success of each earlier crisis is the foundation for the success of each later challenge.

Although identity is established in adolescence, the successful resolution of each previous psychosocial challenge contributes something to the make-up of the healthy ego identity. Infants learning trust are forming in their minds an enduring representation of the mother. This representation should guide growing children into understanding when to trust others and when not to trust them. Other childhood psychosocial challenges establish autonomy, initiative, and industry. Achieving these previous psychosocial functions facilitates establishing identity in adolescence.

NORMATIVE DEVELOPMENTAL CHANGES

Many theorists would agree that identity development begins with children establishing autonomy, recognizing that they are individuals separate from their mother. Autonomy and self awareness begins in the second year. It can be observed when children talk about themselves, using the concept of the self, when they resist control by parents, and recognize themselves in a mirror. Self concept starts to develop shortly after self awareness is established. Self concept is the rudimentary definition of self based on a collection of disconnected traits. The self concept relies on role models to suggest standards and preferences.

From 3 through 6 years of age, children nurture their self concept by making choices and following through on those choices. They experiment in this stage with doing things on their own. They are often told during this time period that what they have chosen to do is wrong. The shame that they feel in these situations leads to the beginnings of the self-evaluation that is so important in the next stage.

Across many cultures, middle childhood, from age 7 until the onset of puberty, is a time of increased responsibility and privilege. Children begin to learn what their

culture deems important. More than in earlier years, they are involved in peer groups, putting them in a position to constantly compare themselves to others. When that comparison is favorable, they are inspired to work and accomplish more. When that comparison is not favorable, they may feel inferior to classmates. During this period self efficacy develops and becomes significant. Self efficacy is the attempt to assess one’s worth through comparison with others.

According to Erikson, the most important process of identity development takes place during adolescence. During this time, individuals must establish their identity in order to make the transition from childhood to adulthood. Adolescents enter a psychosocial moratorium, which is a period of relative freedom from societal expectations. During this time, they feel free to experiment with different personalities and roles. From Erikson’s perspective, everything that was established about self in childhood is re-evaluated in adolescence. Some of the components of the self concept, self worth, and childhood personality may be retained or rejected in the adolescent’s search for identity. Adolescents have to internalize a comprehensive and consistent set of affirmations regarding their own strengths, weaknesses, values, and career choice. The positive influence of family and friends is important in this process, but the commitment must be made by adolescents as individuals. This process requires much experimentation and exploration, particularly in personality and vocational roles (Santrock, 2007).

The identity established during adolescence represents a major accomplishment. By young adulthood, individuals who have achieved their identity are prepared to adapt and contribute to society. That identity is expected to endure. However, many theorists who study identity achievement recognize that there is still much refinement, re-evaluation, and recommitment of identity in later life.

THE KEY THEORIES OF IDENTITY DEVELOPMENT

Although Erikson’s theory of identity development is widely cited, other theories provide important knowledge about identity and its development. The attachment theories emphasize the value of the trust and security that a child learns from his/her mother in infancy. Social learning theories expand the constructs of self concept and self worth as the basis of self description in late childhood. Cognitive development theory describes the age-related processes leading to a child’s limitation before adolescence and competence during adolescence for establishing identity. Researchers investigating Erikson’s theory of identity development have provided important modifications to the theory.

Attachment Theory. Theorists such as Mary Ainsworth, who studied attachment in infancy, observed and explained concepts similar to those of Erikson. The description of attachment compares to Erikson's description of trust. In his theory, infants who have learned trust grow into children who accept that life has order and purpose. These growing children have a trusting and accepting relationship with their mother. Infants who have learned attachment grow into children who look to the mother for guidance and rely on her as a safe base for exploration. In both cases, these children's personality can be expected to have a basic confidence. Failure in attachment and in trust results in a confused child who is not sure about trusting parents and/or may have little discretion in trusting others.

One difference in the two theories is that Erikson expected trust to be established in the first year. Ainsworth has shown that secure attachment can take as long as 18 months. Another difference is the strength of the influence on later development attributed to the mother-child bond. Ainsworth sees attachment as the most important influence on development. For Erikson, that influence is modified by the resolution of later psychosocial crises.

Social Learning Theory. As noted above, once self awareness is established, the self concept starts to develop. The self concept is the basic representation in children's minds of who they are and what they are like. Social learning theorists emphasize that the self concept is built upon the identification with role models, an assessment of self worth, and a preferred pattern in relating to the external world (Carver & Scheier, 1992).

Children learn to relate to the world through modeling and imitation of others, particularly role models. The same-sex parent is an influential role model for each child. Other role models in early childhood can be anyone the child admires. Children will identify with a role model and shape their behavior and tastes in imitation of that role model. The influences of a role model can affect individuals' personality, ambitions, interest, and tastes well into adulthood (Carver & Scheier, 1992).

Self worth is based on children's assessment of their capabilities in comparison to others. Children may feel that they are superior or inferior to others or may feel that they are capable but that others do not notice. Often the assessment is classified according to different areas of life such as sports, academics, or friendships. However, too many negative self assessments in the different areas may result in an overall feeling of helplessness.

The preferred pattern of relationships, influenced by the self concept, is different for individual children. Children seek social interaction in different ways. Although one pattern may be clearly seen as being more effective, some individuals are more likely to choose a pattern that is person-

ally meaningful. For example, shy children may admire those children with more outgoing personalities but may continue to relate to others in a quiet manner.

The self concept can be a stronger motivator for behavior than an external reward. If children receive punishment in class for misbehaving, the punishment may not discourage them from repeating the behavior. If the children see themselves as rebels, such a self concept would be encouraged by receiving punishment (Carver & Scheier, 1992).

Cognitive Development. The patterns of development that Erikson describes are related to what Jean Piaget (1896-1980) and the cognitive psychologists recognize about age-related strategies of children in reasoning. There are limits in children's reasoning until adolescence. Before adolescence, individuals are not capable of the cognitive reasoning necessary in establishing identity.

Evidence of cognition in infancy shows in babies' recognizing their mother's voice and smell even from birth. This perinatal cognitive ability facilitates the familiarity that leads to trust. Babies are comforted by their mother's voice and feel secure in her presence.

In early childhood, the self concept is constantly changing because of cognitive limitations. Piaget calls the period between 2 and 6 years of age the preoperational stage. Children at this age cannot use logical strategies. Therefore, they tend to focus on only one feature of an object. Also, children at this age do not understand the identity principle that some things do not change essentially even though they change one of their features. Even in describing themselves, children will focus on only one aspect of who they are without qualifying that aspect or relating it to another aspect of self. When preoperational children try to describe themselves, they cannot be sure they will not change.

During middle childhood, children develop the capacity for logical reasoning, but only in situations with concrete examples, which marks this as the cognitive stage of concrete operations. Children are increasingly capable of classifying and cross-classifying objects and characteristics. As they describe themselves in the stage of concrete operations, more qualifying occurs on the different attributes of self. Also, these individuals express an expectation of stability in their characteristics. Establishment of the psychosocial function of industry relies on the use of these newly learned cognitive capabilities. Through classification, children can identify their own strengths and weaknesses while being able to rank peers on their related abilities. Also, children can recognize that being inferior in one area does not make one inferior in another.

During adolescence individuals can reason beyond the concrete. Adolescents have increased capabilities for abstract reasoning. With this ability comes awareness that they have a future for which they need to prepare. This unexpected realization is the beginning of the identity crisis.

Other Identity Theories. Many theorists investigating identity achievement have expanded or modified Erikson's ideas. James Marcia investigated the major influences on identity achievement and identified four possible outcomes or statuses of the identity crisis based on whether the crisis has been met and a commitment has been made.

As with Erikson, Marcia sees the identity crisis as beginning when adolescents recognize the need to establish an identity that can prepare them to meet the challenges of adulthood. Marcia agrees with Erikson that adolescents need to explore the many possibilities in personality roles and career choices as well as lifestyles. Identity achievement is recognized as individuals gain a clear understanding of their own strengths and weaknesses and a clear set of personal standards.

For Marcia, true identity achievement is based on meeting the challenge and making the commitment. Some adolescents try to avoid the crisis; some try to avoid the commitment; some try to avoid both. If either the challenge or commitment is avoided, role confusion takes one of three forms. These three forms of role confusion in addition to identity achievement constitute the four identity statuses proposed by Marcia. Identity achievement is the first status. The second status is foreclosure, when the adolescent avoids the challenge by making a commitment without any exploration. This happens often when individuals surrender to the plans that their parents have made for their life. The third status is moratorium, when the youth perpetuates the exploration and challenge without making a commitment. Moratorium is not necessarily an unhealthy status. Because adolescence continues as long as society allows, the search for identity characterized by the moratorium status may continue into young adulthood. The fourth status is diffusion, when adolescents avoid the challenge and refuse to make a commitment. The danger of this status is that diffused adolescents are weak in resisting negative influences.

According to Santrock (2004), some experts investigating identity development challenge Erikson on several points. First, these experts have found substantial evidence that identity formation does not begin or end in adolescence. They also have found that it takes more time and is less dramatic than Erikson expected.

Later research found that moratorium may last into the college years. However, this finding does not contradict Erikson because Erikson, in his day, felt that more adoles-

cents should attend college as a time of psychosocial moratorium. In contrast to the late 2000s, fewer adolescents attended college in the 1950s when Erikson was forming his theory. The age range he used to illustrate the identity challenge was appropriate for his time.

IDENTITY DEVELOPMENT AND SCHOOL ADJUSTMENT

During grade school years, children are still building their self concept. Choosing the right role models is very important during this time. Also important is developing a sense of industry, knowing what one's capabilities are. The social interaction with peers plays a role in supporting the self concept. School adjustment interacts with the positive development of the self concept.

Children's self concept leads them to associate with peers and influences the way they relate to those peers. In trying to understand their competence, these children compare themselves with others. If that comparison leads to a sense of self competence, the children will want to associate and cooperate with other children more than if that comparison leads to a sense of incompetence. If children define themselves as good students, they will want to live up to that self concept. Children who see themselves as loners will be more content to stay away from other children. A teacher can encourage children to develop a positive self concept.

A major threat to the self concept and self esteem of a school-age child is grade retention. One common reason for holding children back one year in the early grades is that these individuals are too immature for age-appropriate grade placement. However, retention has not been shown to have any long-term benefits and it may actually harm the child emotionally. "Children rate retention as the third most horrible thing they can imagine" (Lawson, 2007, p. 89).

VARIABLES REGARDING IDENTITY DEVELOPMENT PROCESS, GENDER, AND ETHNICITY

The development of gender identity leads to conceptual frameworks of perceived appropriate behavior and interests associated with gender. These concepts are influenced greatly by the same-sex parent who becomes a role model for establishing the appropriate gender role. The gender concepts developed in childhood will influence how identity is composed in adolescence. For adolescents from a minority ethnicity, the development of ethnic identity is an important part of identity achievement. In many cases, the preparation for adulthood is the first time that these adolescents have to confront their feelings about their background. While being exposed to alternative sources of group identity from the dominant culture, adolescents have to maintain

connectedness with their own ethnicity. Researchers have found that those who establish and maintain an ethnic identity tend to have higher self esteem (Santrock, 2004).

Erikson found gender differences in vocational exploration with men more concerned with establishing a career and women more concerned about establishing a family. These claims were supported by research in the 1960s and the 1970s, but subsequent research has not found any support for gender differences. Women in the 2000s are just as likely to be career-oriented as men are (Santrock, 2007).

RISK AND PROTECTIVE FACTORS FOR SUCCESSFUL IDENTIFY DEVELOPMENT

Successful identity achievement is developed through accepting traditional values and expressing them in a contemporary manner. Therefore, adolescents need the influence of parents for traditional values and the influence of friends for contemporary expression. However, too much influence from either parents or friends may interfere with the adolescents' personal commitment.

Parenting styles influence the achievement of identity in adolescence. A parenting style emphasizing high standards and high communication encourages adolescents' exploration in a supportive environment. A parenting style that emphasizes high standards but low communication may interfere with the healthy exploration of identity potential. Permissive parents who do not establish standards for adolescents are encouraging a diffused identity with no clear commitments (Santrock, 2004).

SUGGESTIONS FOR TEACHERS AT VARIOUS GRADE LEVELS

Teachers can enhance children's identity development at all grade levels by taking an interest in the individual students and asking them to describe their impressions of self. This can be done as part of an age-appropriate class assignment. In preschool, during group conversation, the teacher can ask the children to describe their favorite memory. Although their memories will not go back too far, what the children describe will convey the influences of their developing self concepts. In grade school, a writing assignment might relate to the individual children's likes and dislikes, their favorite heroes, or their capabilities. In high school, students can be given a research assignment to explore specific vocations or the world of work in general.

Teachers should watch for signs of learned helplessness in grade school. If children describe themselves as individuals who cannot succeed, they will shirk the challenges of the classroom. A teacher can intervene by encouraging such students one-on-one or by establishing classroom support groups (Woolfolk, 2007).

It is important that children are constantly given the opportunity to succeed at increasingly challenging tasks. Teachers should avoid inappropriate comparison or competition with others. Students should be encouraged to compete against themselves to improve upon their previous accomplishments. The teacher should take the student's failing as an opportunity to point out how many times the child has succeeded (Woolfolk, 2006).

The high school teacher should be careful not to give into stereotyped perceptions of adolescence. Most adolescents, even those who appear to be antisocial, are involved in healthy exploration. The high school teacher should take the attitude that these students are young adults with the expectation that they will behave as adults. Most adolescents will feel free to approach such a teacher with their problems and concerns. Also, treating the young people as adults will lead to their seeing disciplinary actions as a natural consequence for misbehaviors.

IMPRESSION MANAGEMENT

Impression management refers to the process in which individuals attempt to influence the opinions or perceptions others hold of them. Impression management, also referred to as self-presentation, is a goal-directed activity that helps to establish the boundaries of what is considered acceptable behavior; conversely, it also aids in defining

what behavior will be met with disapproval. In the classroom, impression management behaviors allow students to make sense of the complex social stratum and help to inform their social identities.

MODELS OF IMPRESSION MANAGEMENT

Writings on impression management were introduced by Goffman (1959). In his seminal book, *The Presentation of Self in Everyday Life*, Goffman shows that the individual is influenced by his or her environment and the perceived audience. Furthermore Goffman posits that the objective of individuals is to convey an image that is consistent with their desired goal (spoken or unspoken). While Goffman's theory is constructive (impressions can influence how individuals perceive themselves), Jones and his colleagues (Jones & Pittman, 1982; Jones & Wortman, 1972) championed strategic self-presentation. Strategic impression management emphasizes the power dynamics and goals that characterize most social interactions. Jones (1990) suggested that the goals or motives in strategic impression management are aimed at negotiating the power dynamics in social relationships such that the individual's power is never diminished.

Leary and Kowalski (1990) elaborated on the work of Goffman (1959) and Jones and his colleagues. Leary and Kowalski's (1990) model is distinctive, in that it elucidates reasons why people are concerned with others' impressions and why they choose to engage in specific impression management behaviors. Though other conceptualizations of impression management did not draw such a distinction, Leary and Kowalski's model posits that impression management is comprised of two distinct processes: *impression motivation* and *impression construction*. Impression motivation, they argue, is a function of several factors (goal-relevance, value of desired outcomes, discrepancy between desired image and current image) that determine whether or not an individual will engage in impression-related attempts. Goal relevance refers to whether or not one's actions are salient to obtaining prescribed goals. Value of desired goals refers to the importance placed on obtaining a particular goal; the value increases as the number of available desired objects decreases. The discrepancy between the desired image and the current image refers to the individual's perception of the closeness between the image others hold and the image he or she wants others to hold.

The second process, impression construction, is influenced by two intrapersonal and three interpersonal factors. Self-concept and desired image constitute the intrapersonal variables; role constraints, target values, and current or potential social image represent the interpersonal variables. Leary and Kowalski asserted that the

self-concept variable is the chief impetus of a learner's impressions. Accordingly, students will display what they believe is their greatest asset. Thus, if academics do not constitute the best part of their self-concept, impression management for academic diligence will be low. Furthermore, the motivation to impression manage will be influenced by not only what the students think they are, but what they would like to be and not be; this refers to the second intrapersonal variable, desired and undesired identity image. It appears that attempts to impression manage are, in part, a function of the interaction between these two components. As mentioned above, three interpersonal variables also contribute to impression construction. The *role constraint* variable suggests that individuals who act in a manner that is inconsistent with social expectations risk losing the power associated with that position. The second interpersonal variable, *target values*, indicates that an individual will often modify or change his or her image so that it corresponds to an assumed value of a model. Lastly, *current or potential image*, states that impressions are further shaped by learners' perception of how they are presently perceived and how they believe others will see them in the future.

HOW IMPRESSION MANAGEMENT INFLUENCES CLASSROOM BEHAVIOR

Impression management theory provides a useful framework for understanding students' behavior in classroom situations. Studies on impression management generally indicate that academic diligence or effort is likely when individuals perceive their image as consistent with expectations of being academically competent and that the rewards of projecting such an image are greater than its possible repercussions. Research has demonstrated that if the potential repercussions of projecting an academically diligent image are sufficiently threatening, the student is less likely to project that image. The presence of multiple (and often competing) audiences necessitates an individual student's need to consider what image he or she is willing to project. It has become increasingly evident that classrooms are more than just academic environments; they are also social settings in which students must negotiate the demands/expectations of multiple audiences: the teacher and other students. While research has consistently demonstrated that teachers value and reward students who exhibit academic effort, peer groups, especially the "popular crowds," tend to ostracize those students whose identity or image is based largely on academic effort. Thus, while teachers possess legitimate power over the student, popular peers possess referent power, both of which are instrumental in determining the impression a student projects.

DEVELOPMENTAL AND INDIVIDUAL DIFFERENCES

Studies on impression management have also indicated that development affects impression management. One key assumption of the Leary and Kowalski (1990) model (as well as other explanations of impression management) is that the student must possess the ability to analyze potential interactions (including understanding what others value) and the ability to take another's perspective. Selman (1980) labeled these abilities as Level 3 perspective taking and argued that these abilities do not generally manifest until middle and junior high school years. However, a number of researchers have demonstrated that these abilities develop earlier than Selman (1980) argued. In their study of fourth, sixth and eighth grade students, Juvonen and Murdock (1995) found that younger students were able to demonstrate an understanding of the expectations of others. Another significant developmental difference identified by the authors was that older students, and not younger ones, modified their explanations of effort based on intended audience. What this finding seems to suggest is that while younger students are aware of what others expect, their perception that other students' and teachers' values are congruent represents a lack of understanding of the complexity of multiple audiences. Thus, it appears that the impression strategy a student employs is significantly influenced by cognitive development.

Though Juvonen and Murdock (1995) did not observe significant differences between males and females, gender differences in impression management related to academic diligence have consistently indicated that females are more likely than males to present an image that conveys a desire to be seen as conscientious of academic activities (Grabill, Lasane, Povitsky, Saxe, Munro, Phelps, & Straub, 2005). That this finding has been consistently reported is not surprising. Although academic achievement is seen as a masculine trait, this seems to apply only to one's natural abilities; effort (diligence) is largely viewed as a feminine characteristic. Impression management theory posits that since achievement with effort (compared to "natural" achievement) is by and large a feminine quality, most males would prefer to project images that would not call into question their masculinity for fear of disapproval.

Though few studies have explicitly investigated ethnic differences in impression management, it has been argued that many minority students (particularly African Americans) view academic diligence differently from Caucasian students. Several researchers (e.g., Czopp, Lasane, Swigard, Bradshaw & Hammer, 1998; Fordham & Ogbu, 1986) have reported that African American students attempt to conceal their academic selves for fear of social disapproval; instead, many of these students project an impression con-

sistent with "Joe Cool," an image that is less concerned with academic effort. Furthermore, studies have suggested that the impression that some minority students adopt is based on the belief that academic diligence is a mostly "White" phenomenon; thus, to project an academic-conscious image would be perceived as denying one's culture. Though this theory has received considerable attention, additional research is warranted.

IMPLICATIONS FOR EDUCATORS

The ability of educators to recognize and acknowledge the effects of impression management on academic performance has important, yet feasible, implications for their ability to work effectively with diverse student populations. Foremost, educators need to actively and aggressively diversify the teacher pool. Administrators communicate to students their attitudes regarding academic achievement through those persons whom they hire to educate. Thus, there needs to be fair representation of men and women in academically rigorous courses as well as less academically rigorous ones. To that end, all physical education classes cannot be taught by Mr. Jones and not all of the language arts classes should be taught by Mrs. Smith.

Second, teachers are encouraged to reflect on their own attitudes towards students who tend to display academically disidentified behaviors. As research suggests, students' struggles with the problem of multiple audiences, for example, may manifest as academically disidentified (Osborne, 1995) or unconcerned behavior; this manifestation may, in turn, prejudice teacher-student interactions, particularly evaluations. It is possible (and likely) that unexamined attitudes could lead to interactions that result in negative evaluations, thus reinforcing an adversarial relationship with academically minded individuals and fostering a negative association with academic-related activities.

Lastly, teachers need to realize that students do contemplate the challenges of negotiating beliefs and stereotypes related to academic diligence. Teachers might consider purposefully addressing this issue with students in an effort to monitor and correct any detrimental views students may harbor. Also, an added benefit to this practice is that students may become more engaged in the learning process and, as research has indicated, students who are engaged in the learning process tend to evidence more positive long-term consequences.

Chammie C. Austin

IMPULSIVE DECISION-MAKING

Decision-making can range from a highly rational style involving careful consideration of cognitive cues to a very impulsive act-without-thinking process that relies primarily on affective and physiological cues. Impulsive decision-makers are those who operate on the far end of this decision-making continuum. Whereas rational decision-makers carefully consider beliefs about the consequences of their actions when making decisions, impulsive decision-makers often fail to even consider such consequences, relying instead on cues that are often salient in the immediate present. As a result, individuals with an impulsive decision-making style often make decisions without a great deal of thought, fail to plan ahead for a variety of situations, and are more likely to act on impulse as compared to their rational decision-making counterparts (Donohew et al., 2000, 2004).

Impulsive decision-making is not, in and of itself, believed to be a personality trait. It is, however, thought to be a tendency that flows from the trait of impulsivity.

Impulsivity itself is conceptualized in different ways by different researchers in the field. For instance, some researchers treat impulsivity as a unidimensional trait (Grano et al., 2004), whereas others have provided evidence for multiple dimensions of impulsivity, identifying two (Dawe & Loxton, 2004) or as many as four dimensions (Whiteside & Lynam, 2001). The four-dimensional conceptualization of impulsivity includes: 1) urgency, 2) lack of premeditation, 3) lack of perseverance, and 4) sensation-seeking. Additionally, whereas other researchers view impulsivity and sensation-seeking (or thrill-seeking) as a single "supertrait" (Zuckerman & Kuhlman, 2000), some view impulsivity and sensation-seeking as different, albeit related dimensions (Donohew et al., 2000, 2004).

RELATION OF IMPULSIVE DECISION MAKING TO PERSONALITY

While impulsivity is included at some level in many theories of personality, precisely how it fits into such theories, as well as how much emphasis it receives, tends to vary (Whiteside & Lynam, 2001). For instance, Eysenck and Eysenck's (1985) Three Factor Theory of personality focuses on the roles of neuroticism, extraversion, and psychoticism in an explication of personality processes. It considers impulsivity to consist of two components: venturesomeness and impulsiveness, which are thought to correspond to the extraversion and psychoticism factors, respectively.

McCrae and Costa's (1990) Five Factor Model of personality is focused on neuroticism, extraversion, openness to experience, agreeableness, and conscientiousness, each of which is composed of six facets. In this model, impulsivity is represented by a number of facets across the factors. For instance, the neuroticism factor contains an impulsiveness facet and the conscientiousness factor contains both self-control and deliberation facets. Facets on other dimensions, such as extraversion's excitement-seeking facet, also overlap with conceptualizations of impulsivity (Whiteside & Lynam, 2001).

Finally, Zuckerman and colleagues' (1993) Alternative Five Factor Model gives impulsivity perhaps its most prominent role compared to these other theories, combining it with sensation-seeking in a single "supertrait" termed "impulsive sensation-seeking." This model considers impulsive sensation-seeking to be one of five major traits that drive personality. The others are neuroticism-anxiety, aggression-hostility, activity, and sociability. Although early work with this model focused solely on the role of sensation-seeking as a predictor of a variety of behaviors, later work combined sensation-seeking with impulsivity to form this single trait (Zuckerman & Kuhlman, 2000).

IMPULSIVE DECISION MAKING AND ACADEMIC OUTCOMES

One question concerns how impulsivity and impulsive decision-making affect behaviors. A number of studies exist on this topic across a variety of areas, with the overall theme being one of association with maladaptive and problem behaviors. For instance, impulsivity has been found to be related to a variety of antisocial behaviors, delinquency, and a lack of social adjustment (Cooper et al., 2003; Schwartz et al., 1999) and, thus, is a focal point among many theories of crime (Lynam & Miller, 2004). Impulsivity is a key diagnostic criterion for numerous disorders in the Diagnostic and Statistical Manual for Mental Disorders, or DSM-IV (American Psychiatric Association, 2000; Whiteside et al., 2005). Further, impulsive decision-making (and more generally, impulsivity) has been widely studied in the area of health risk behaviors among youth, exhibiting positive associations with alcohol use, drug use, risky sexual behavior, eating disorders, and even body piercing (Cooper et al., 2000, 2003; Dawe & Loxton, 2004; Donohew et al., 2000, 2004; Greif et al., 1999; Hoyle et al., 2000; Zuckerman & Kuhlman, 2000).

In the specific realm of education, impulsivity has been found to relate to, and may adversely affect, a number of key academic outcomes. Indeed, the educational process is a long-term, goal-oriented task. Given this fact, theoretically it might be expected that such an undertaking would be adversely affected by impulsivity, given that impulsive individuals exhibit a tendency to act on immediate demands instead of making decisions based on long-term goals (Spinella & Miley, 2003).

The research as of 2008 in the area of impulsivity and academic outcomes does, in fact, bear out this correlation. Impulsivity has been shown to be related to educational underachievement in a number of studies (Cooper et al., 2003; Lynam & Miller, 2004; Spinella & Miley, 2004; Weithorn, Kagen, & Marcus, 1984). In fact, those who are impulsive are more likely to fall behind their peers and achieve lower grades compared to those who exhibit a more rationale style. For instance, Meade (1981) found that first grade students with a low socio-economic status who exhibited impulsive behavior had lower grades and lower achievement scores than their peers, even when IQ was held constant. Among older students, another study found impulsivity and college students' grades to be inversely related, with higher impulsivity relating to lower grades (Spinella & Miley, 2003). Some researchers have even gone as far as to suggest that there is a positive association between impulsivity and academic failure (Vigil-Colet & Morales-Vives, 2005).

In addition, although limited research has been conducted on the association between impulsivity and academic cheating, some studies have examined the link

between the two (Anderman & Cupp, 2006; Kelly & Worell, 1978; Miller et al., 2007). For instance, in one study, college students were given the opportunity to falsify scores in order to obtain course credit. Among the female participants, the students who cheated were significantly more impulsive than were the non-cheaters. Another study demonstrated a positive association between impulsivity and academic cheating among a large sample of high school students (Anderman & Cupp, 2006). These researchers have suggested that impulsive students experience difficulty with self-regulation, which leads to decreased self-control, and, in turn, increased cheating.

Finally, there is a large literature in the specific area of Attention Deficit Hyperactivity Disorder (ADHD). ADHD is itself characterized by impulsivity, inattention, and hyperactivity (American Psychiatric Association, 2000; Hoza, Owens, & Pelham, 1999). In the context of ADHD, impulsivity can manifest itself in a number of ways, including interrupting others, blurting out answers, not listening to instructions before beginning a task, and not waiting for a turn. A criterion of ADHD is that such difficulties impair functioning in academic, occupational, or social settings (American Psychiatric Association, 2000). Academic underachievement has also been identified as a primary long-term outcome associated with ADHD (Manuzza et al., 1993), with up to 80% of students with ADHD exhibiting problems in academic performance (Cantwell & Baker, 1991). Though impulsivity is a part of ADHD, impulsivity and impulsive decision-making can occur exclusive of ADHD (Furman, 2005). Thus, both impulsive ADHD and impulsive non-ADHD students may be at risk of similar poor academic outcomes (Merrell, & Tymms, 2001).

SUGGESTIONS FOR PRACTITIONERS

One challenge is identifying strategies to be used by those who work with impulsive youth. A primary obstacle which impulsive students struggle with is their lack of metacognition, that is, their ability to be reflective and think about thinking. Therefore, it is important to help impulsive students learn to think about making decisions instead of acting before thinking. Another general consideration is the fact that impulsive students do not consider alternatives effectively; therefore, it is important for those working with such students to emphasize the consideration of alternative options and alternative ways of thinking in decision-making (Margolis et al., 1977).

Moreover, many strategies for reducing students' impulsive behaviors have been reported in the literature. Cognitive and/or behavioral strategies are popular approaches given that students' problems with impulsivity are in regards to their thinking and behaviors (Baer & Nietzel, 1991). Self-instruction training, in which students

learn to guide themselves through tasks by asking and then answering a series of questions, is a commonly used treatment (Baer & Nietzel, 1991). For example, in one self-instruction procedure, the impulsive student learns to size up the demands of a task, cognitively rehearse the task, guide their performance through self-instruction, and where appropriate, give self-reinforcements (Meichenbaum & Goodman, 1971).

Finally, the need for effective in-classroom interventions for impulsive students has also been identified. Given that there is a connection between impulsivity and a lack of metacognition, in-classroom interventions may help in this area (Bornas & Servera, 1992). In-class training, as opposed to out-of-class training, may be important in helping students to generalize learned skills to the classroom environment. Having students use strategies that are taught in real learning contexts may be important (Bornas & Servera, 1992), as is having peers model appropriate behaviors (Margolis et al., 1977). In addition, impulsive students may benefit from a classroom atmosphere that is mastery-oriented (Anderman & Cupp, 2006).

INDIVIDUAL VS. GROUP ADMINISTERED TESTS

Psychological and educational assessment of students has been prominent since the early 1900s. The results garnered from these assessments have been used for a myriad of purposes, such as identifying children who (a) are suspected of having learning difficulties, (b) qualify for gifted programs or programs requiring specific talents (e.g., enrollment in a music or arts program), or (c) may be suffering from emotional distress (e.g., depression, anxiety). Further, group-based data focusing on a chosen index (e.g., standardized achievement scores, school drop-out rates) have also been compared across school districts and/or across states to examine learning outcomes. In common among all assessment processes is the gathering of data to make informed educational and mental health decisions (Neukrug & Fawcett, 2006).

The term *assessment* includes a broad array of methods. Sattler (2001) outlined four main types, or pillars, of assessment, each of which is complementary and adds unique information not found in the other methods. These pillars

include (a) interviews with parents, teachers, and children, (b) observations of the child's behavior, and (c) informal assessment procedures such as reviewing class work, school records, or personal documents, for example, diaries, drawings, and self-report logs. The fourth and most frequently used method is the administration of norm-referenced tests (most notably intelligence and achievement measures) for diagnostic purposes. Such tests compare a child's results, in standardized form, against an established norm group. Considering the emphasis that teachers, parents, and schools often place on the results of norm-referenced tests, this entry focuses on this particular assessment method.

The results derived from norm-referenced tests often have been used to establish or support many legislative and educational policies (see Cohen & Swerdlik, 2002). The ramifications of these policies to schools, students, and the larger community underscore the need for tests to demonstrate sound psychometric properties (i.e., evidence of reliability and validity) and appropriateness for their intended use (Anastasi, 1988; Moreland, Fowler, & Honaker, 1997). A key factor in this regard is the manner in which tests are administered. Indeed, from the beginning of psychological testing much attention has been devoted to ensuring that test scores are invariant regardless of whether they are administered individually or in a group setting (Geisinger, 2000; Kline, 2005). Although stringent measures have been taken to control method variance, each format contains inherent advantages and disadvantages. This entry reviews the most salient aspects of each format.

A BRIEF HISTORY OF TESTING

The history of psychological testing is one marked by necessity followed by innovation (Geisinger, 2000). Although the lineage of psychological measurement dates back at least 4,000 years (Thorndike & Lohman, 1990), the first modern test of intelligence was created at the turn of the 20th century, in response to problems reported by French public schools experiencing a sharp increase in student enrollment. The overcrowded conditions prompted a decision to remove children from the regular education classroom who were not learning at a satisfactory level. The 1905 work of Alfred Binet (1857–1911) and Theophile Simon led to the construction of a test containing a series of brief mental tasks, which could be individually administered to children ages 3 to 11. Revisions to this original test included expanding the age range to adulthood, increasing the number of items comprising each test, providing standard directions for administration, and introducing the concept of mental age, which was the chronological age of a group of typically developed children who performed at the same level as the examiner (Aiken, 2006).

A short time later, American psychologists made significant revisions to the original Binet-Simon scale. These changes included arranging the items in order of difficulty and assigning points for the level of correctness of an examinee's response. The most durable of these changes was provided by Lewis Terman and colleagues, who gathered extensive normative data on the Binet-Simon scale from hundreds of children in the Stanford, California, area. From this data, numerous revisions were made, most notably the inclusion of an intelligence quotient or IQ—a quantitative score that was defined as the ratio of the child's chronological age and mental age (Neukrug & Fawcett, 2006). Later known as the Stanford-Binet Intelligence Test, Terman's revised test served as the standard of testing for the first two decades of the 20th century (Aiken, 1996) and ushered in both the intelligence testing movement and the clinical testing movement (Boake, 2002; Cohen, Swerdlik, & Smith, 1992). The original Binet-Simon scales and their subsequent modifications also served as the prototype for most modern intelligence tests.

Group testing also was developed to address a pressing concern. The involvement of the United States in World War I prompted the need for a group-based cognitive test that could quickly determine if recruits were fit for military service and to identify those who could be trained as officers. Although considered crude by 21st century standards, two multiple-choice "intelligence" tests were created and administered to almost 2 million recruits. The Army Alpha was designed and administered to recruits who were literate and proficient in English, while the Army Beta was administered to foreign-born recruits or those who could not read with proficiency. Although both versions underwent significant revisions, their basis served as the foundation for most group-based intelligence tests used today. Further, these early tests served as the prototype for group tests examining other constructs (e.g., achievement, specific aptitude, psychopathology) across various environments (e.g., schools, mental health clinics) (Neukrug & Fawcett, 2006).

ADVANTAGES AND DISADVANTAGES OF INDIVIDUAL TESTING

Individually administered norm-referenced cognitive and achievement tests have been used for a wide variety of purposes. In conjunction with other norm-referenced tests and assessment methods, cognitive and achievement tests have typically been used to provide in-depth information on student's (a) intellectual functioning or academic standing in comparison to same-age peers, (b) ability to process certain mental or academic tasks, which can facilitate diagnostic impressions such as learning disabilities, giftedness, or mental retardation, and (c) initial or continuing eligibility for special education services. In most cases, cognitive and

achievement tests provide a wide array of specific tasks that the student is asked to perform either within a given time frame or according to specific scoring guidelines. Each test is concluded when the allotted time is reached (i.e., a timed test) or the student gives a continuous number of failed responses (i.e., a power test). Most tests aggregate the task scores to yield a general or overall score, which is assumed to indicate a student's global level of cognitive or achievement functioning. Nevertheless, as the general score can be influenced by extremely high (or low) performance on one or more specific tasks, composite scores also are computed to assess functioning within a specific domain. For example, cognitive tasks that measure a student's verbal reasoning abilities and general knowledge would be combined to form a verbal composite. Likewise, achievement tasks that assess a student's aptitude for solving math problems or for identifying numbers would be combined to form a math composite.

There are numerous advantages for using individually administered cognitive and achievement tests. First, direct one-to-one attention allows the student and examiner to establish solid rapport, which is essential for obtaining valid results (Sattler, 2001). Also, the examiner has direct control of the testing environment, which includes ensuring that the environment itself is conducive to optimal student performance (e.g., making sure the temperature of the room is not too hot or cold, eliminating non-relevant stimuli that would distract the student). Second, the one-to-one attention allows the examiner to observe student behaviors that may be interfering with task performance but not reflected in the score (e.g., fatigue) or assist in diagnosis (e.g., difficulty remaining in seat). Third, because most task items are orally administered by the examiner, little reading is required by the student, which makes it possible to test very young students or those with limited reading skills (Thorndike, 2005). Finally, scores from individual tests can be interpreted across a variety of levels. For example, in addition to determining the general cognitive or achievement level of the student, composite and even subtest scores can be examined to determine specific processing deficits. Thus, individually administered tests yield detailed information on a student's cognitive or achievement functioning that is not typically obtained from group administered tests.

Nevertheless, there are some disadvantages to using individually administered tests. Perhaps the biggest limitation is the cost of the tests themselves, both monetarily and with respect to time. With the cost of most major tests close to or exceeding \$1,000 (U.S.), purchasing these tests places a financial burden on school districts, especially those with limited economic resources. Further, learning to administer and interpret the results from the tests (particularly the cognitive tests) requires extensive training, and administration time ranges from one to

four hours. Finally, the tests purposely include a wide array of tasks so that an adequate sampling of important cognitive or achievement domains are covered (Anastasi, 1988). Nevertheless, one of the most persistent criticisms (particularly with regard to cognitive tests) is that the underlying conceptual framework of most tests (and thus the tasks included) is largely atheoretical or based on different theories of intelligence (Flanagan & Ortiz, 2006). For example, the commonly used scales in the Wechsler series were originally based on clinical practice rather than a specific theory, while the original Stanford-Binet scales were based on the theory of general intelligence, or *g*, which proposed that all mental abilities can be explained by a single global intellectual functioning (Thorndike, 2005). More contemporary cognitive tests are based on neurophysiological modeling of the brain, while others are based on theories that emphasize broad fluid (i.e., innate) and crystallized (i.e., learned) abilities (Harrison & Flanagan, 2005). Thus, the use of one test may not adequately address domains covered by another test. In the early 2000s, attempts were made to create a cross-battery approach, whereby examiners are not relegated to using one test but instead use portions of multiple tests to ensure that specific domains are covered (e.g., McGrew & Flanagan, 1998). However, more research is needed to verify its clinical utility.

ADVANTAGES AND DISADVANTAGES OF GROUP TESTING

Most students will be administered a group administered cognitive or achievement test during their studies. Indeed, of the millions of cognitive tests that are administered to students annually, only a small fraction of these are individually administered (Cohen & Swerdlik, 2002). Considering their practicality, group tests are used across a variety of environments, including military, industrial/organizational, and educational. Thus, group administered tests have a broader application than individual tests (Aiken, 2006). Like their individually administered counterparts, most group administered tests consist of subtests that assess a variety of cognitive or academic domains and are either timed or power tests. However, the scoring format for most group administered tests is multiple-choice, which is less flexible and yields much less diagnostic information. For this reason, school-based group administered tests are used as screeners to determine whether further evaluation (often using an individually administered test) is warranted.

From their inception, it was clear that group administered tests could address some of the limitations inherent in individually administered tests. For example, by using only printed materials and following a standardized administra-

tion procedure, the financial and personnel resources are much less than the costs associated with individually administered tests. Further, most group administered tests have standardized and computerized scoring systems, which reduces the time necessary to score the protocols and thus minimizes scoring error. Moreover, given the nature of the format, group administered tests can be given to as many students who can comfortably fit into a room, which reduces test administration time and increases testing efficiency. Finally, considering the potentially unlimited number of students who would be administered a group administered test, the norms created are often based on a sample that is much larger than individually administered tests. This advantage allows for a direct comparison of scores across select demographic variables (e.g., race, disability status) that may not be possible when using individually administered tests.

Nevertheless, there are important disadvantages when considering group administered tests. For example, the format does not allow for in-depth observations of individual students as they complete the test. Thus, behaviors such as fatigue, low motivation, anxiety, hunger, and other states that may interfere with performance are not observed. Further, because the examiner may be less trained in the nuances of the test (in comparison to those who administer individual tests), the examiner may break standardization and inadvertently (and inappropriately) answer students' queries or not be able to monitor the testing environment with the same fidelity as can be given to the individual testing environment. Another limitation is the restriction of responses to multiple choice, whereas items on many individually administered tests have different levels of scoring depending on the complexity of the response. In this regard, group administered items may unduly penalize creative or original thinkers. Further, although the sample size of a group administered test may be large, it may also not be representative of children of a particular demographic. For example, many group administered cognitive and achievement tests are normed by students who take the test in the fall and in the spring. However, many students may choose not to take the test (when given a choice) or not be motivated to perform their best on the test (Aiken, 2006). Finally, the results of group administered tests can be used inappropriately. For example, the data obtained from such tests can be used to diagnose and place students into special programs, which should only occur from individually administered tests (Cohen & Swerdlik, 2002).

INDIVIDUALIZED EDUCATION PROGRAM (IEP)

Individualized Education Programs, or IEPs as they are commonly called, are an integral part of the U.S. education system. They are the written documents that direct the provision of special education services to students with disabilities who need them. Increasing numbers of students in U.S. public schools have been deemed to need special education services, in a wider variety of categories,

including learning disabilities, speech-language impairments, other health impairments, mental retardation, emotional disturbance, autism, visual impairments, hearing impairments, and others, totaling 13 separate categories in 2004. IEPs are considered a centerpiece of the special education process and, thus, necessary to understand for obtaining a perspective on special education as a whole.

DEFINITION OF THE INDIVIDUALIZED EDUCATION PROGRAM

The Individualized Education Program (IEP) is a written document required for each child who is eligible to receive special education services. It is provided to a student who has been determined first to have a disability and, second, to need special education services because of that disability. The IEP, the team that develops it, and what it must contain are governed by Part B of the Individuals with Disabilities Education Act (IDEA) and amendments to it. The IEP provides information on children's current levels of performance and directs the special services and supports that are provided to students who have IEPs. It includes provisions for defining annual goals, evaluating progress, and formalizing what is to be a free and appropriate public education (FAPE) for the student with the disability.

IEPs have several required components. Among the information that is to be included in IEPs are the following: (1) present levels of academic achievement and functional performance, (2) measurable annual goals, (3) special education, related services, and supplementary aids and services, (4) amount of time students will not participate in general education classes, (5) participation in state or district-wide academic assessments (including accommodations to be provided and reasons for using an alternate assessment if the child will not participate in the regular assessment), (6) initiation date and projected duration of IEP, (7) transition services, and (8) how student progress toward annual goals will be measured and when periodic reports will be provided to parents. Access to and participation in the general curriculum and use of research-based procedures are emphasized in the preparation of IEPs (Yell, Shriver, & Katsiyannis, 2006). States or districts may add to the basic components as they see appropriate, but failure to include all required components has been a source of litigation (Yell, 2006).

LEGISLATIVE HISTORY

The passage of the 1975 Education of the All Handicapped Children's Act (EHA), also commonly known as Public Law 94-142, contained the first requirement for the development of the Individualized Education Program (IEP) for

Individualized Education Program (IEP)

a child with a disability requiring the provision of special education services. Subsequent to the 1975 EHA, reauthorizations of the law refined and adjusted the IEP requirements. Public Law 99 457 (EHA Amendments of 1986) added requirements for early intervention services for infants and toddlers. Public Law 101 476 (EHA Amendments of 1990) renamed the law as the Individuals with Disabilities Education Act (IDEA). Public Law 105 017 (IDEA Amendments of 1997) initiated alignment of IDEA with the Elementary and Secondary Education Act and required participation of students with disabilities in state and district-wide assessments. Public Law 108 446 (IDEA Amendments of 2004) adjusted the name of the law to the Individuals with Disabilities Education Improvement Act and further aligned its requirements to those of the Elementary and Secondary Education Act, particularly its accountability requirements.

With each reauthorization, IEP requirements were adjusted to address the new focus and challenges or needs that were identified during the time since the previous reauthorization. The IDEA amendments in 2004 introduced several adjustments to the IEP, with the intention of addressing the need for increased accountability in line with the requirements of the Elementary and Secondary Education Act, known as No Child Left Behind. The 2004 reauthorization also introduced an easier IEP process, including less paperwork and the need for fewer meetings (President's Commission on Excellence in Special Education, 2002; Yell, 2006).

Among the 2004 provisions were the ability to excuse from required IEP team membership anyone deemed to be unnecessary if agreed to by both school personnel and the child's parents, dropping the requirements to have short-term objectives (except for those students participating in the state alternate assessment) and allowing IEPs to be changed without reconvening the IEP team between annual meetings, as long as the IEP team and the parents agreed. In an attempt to study the idea of having IEP teams meet only every three years rather than the required annual meetings, a pilot program for up to 15 states was initiated in 2004 to test the implementation and consequences of three-year IEPs.

LEGAL REQUIREMENTS

The legal requirements for the Individualized Education Program (including the IEP team and the document itself) encompass not only what must be included in the IEP (see Definition) but also specifics of the process. The IEP team must meet to write the IEP within 30 calendar days of the date that the child was determined to be eligible for special education services. The team must include the child's parents (or guardians), a special education teacher, a general education teacher, a school or local education agency administrator, a person who is able to interpret evaluation

results, and, if appropriate, the child. An individual may fill more than one role. The child's participation is required when the IEP includes a focus on transition services, which must start by age 16. Other individuals may be members of the team, as desired by the parents or school.

Each year, at a minimum, the IEP must be reviewed and revised as needed (unless there is participation in the three-year IEP pilot program; see Legislative History). Attention is paid especially to the IEP goals, progress toward them, and whether they need to be revised, and the placement of the child (where and for how long the child is in specific settings within the school, such as the general education classroom, special education room, or other placements). Every three years, the IEP team must meet to examine reevaluation results, used to determine whether the child continues to meet criteria to be designated as having a disability that requires special education services.

DESIGNING AND IMPLEMENTING IEPs

The actual processes and procedures used in schools and districts to ensure that IEP teams carry out the letter and intent of the law vary and have been the subject of relatively little research. Concerns about the legal requirements have arisen because of perceptions that they have compromised the quality of IEPs (Beattie, Jordan, & Algozzine, 2006). At the same time, the 2004 reauthorization of the law focused on ways to make the process of developing and revising the IEP more efficient and on ways to reduce paperwork in developing IEPs. In practice, states or local education agencies often require or recommend a form to use in developing the IEP so that it meets federal and state requirements. Computer-based IEP development software gained popularity with the perception of increasingly complex IEP requirements. With improvements over time in technology and programming, computer-based IEPs came to be viewed as having the potential to aid in the production of well-thought through IEPs (Wilson, Michaels, & Margolis, 2005).

IEPs are implemented by carrying out the directives of the IEP. Ideally, everyone responsible for implementing the IEP for an individual child has access to a copy of the IEP, and each person knows which responsibilities to implement (Beattie et al., 2006). Along with providing the designated services, supports, and accommodations that are described in the IEP, the IEP defines how the child's progress toward meeting the goals stated in the IEP will be measured. Progress reports designed to indicate the extent to which the child is making sufficient progress to reach goals by the end of the year are given to parents. These progress reports on IEP goals are to be made as often as the parents of children without disabilities are informed of their children's progress.

Despite their importance to the special education process, IEPs often have been inaccessible to those who should use them. Some educators and administrators have treated them as though they define the curriculum for the child with disabilities who requires special education services, rather than as the delineation of the services, supports, and framework for access to the general curriculum provided in the least restrictive environment for each child. In the early 2000s the IEP continued to be the subject of revisions each time IDEA is reauthorized, all the while retaining its central position in the special education process.

Martha L. Thurlow

INFORMATION PROCESSING THEORY

Humans process information with amazing efficiency and often perform better than highly sophisticated machines at tasks such as problem solving and critical thinking (Halpern, 2003; Kuhn, 1999). Yet despite the remarkable capabilities of the human mind, it was not until the 20th century that researchers developed systematic models of memory, cognition, and thinking. The best articulated and most heavily researched model is the information processing model (IPM) developed in the early 1950s. The IPM consists of three main components, sensory memory, working memory, and long-term memory (see Figure 1). Sensory and working memory enable people to manage limited amounts of incoming information during initial processing, whereas long-term memory serves as a permanent repository for knowledge. In this entry, the

information processing model will be used as a metaphor for successful learning because it is well supported by research and provides a well-articulated means for describing the main cognitive structures (i.e., memory systems) and processes (i.e., strategies) in the learning cycle.

SENSORY MEMORY

Sensory memory processes incoming sensory information for very brief periods of time, usually on the order of 1/2 to 3 seconds. The amount of information held at any given moment in sensory memory is limited to five to seven discrete elements such as letters of the alphabet or pictures of human faces. Thus, if a person viewed 10 letters simultaneously for 1 second, it is unlikely that more than five to seven of those letters would be remembered.

The main purpose of sensory memory is to screen incoming stimuli and process only those stimuli that are most relevant at the present time. For example, drivers on a busy freeway in heavy traffic are constantly bombarded with visual and auditory stimuli. To maximize efficiency and safety, they process only information that is relevant to safe driving. Thus, they would attend to road conditions but not buildings they pass as they drive. Similarly, they would attend to sounds of other cars, but not to music from the radio or one passenger's casual conversation with another.

Researchers agree that information processing in sensory memory usually occurs too quickly for people to consciously control what they attend to. Rather, attention allocation and sensory processing are fast and unconscious. Information that is relevant to the task at hand, and information that is familiar and therefore subject to automatic processing, are the most likely types of information to be processed in sensory memory and forwarded to the working memory buffer. Information that is highly relevant may receive some degree of controlled, conscious processing if it is crucial to a task (e.g., attending to salient information such as animals along the road while driving at high speed). However, controlled processing in sensory memory would be likely further to reduce the limited amount of information that can be processed at any given moment.

WORKING MEMORY

After stimuli enter sensory memory, they are either forwarded to working memory or deleted from the system. Working memory is a term that is used to refer to a multi-component temporary memory system in which information is assigned meaning, linked to other information, and essential mental operations such as inferences are performed. A number of different models of working memory have been proposed (Shah & Miyake, 1999). However, the three-component model developed by Baddeley (1998, 2001) is the most common, and will be discussed shortly.

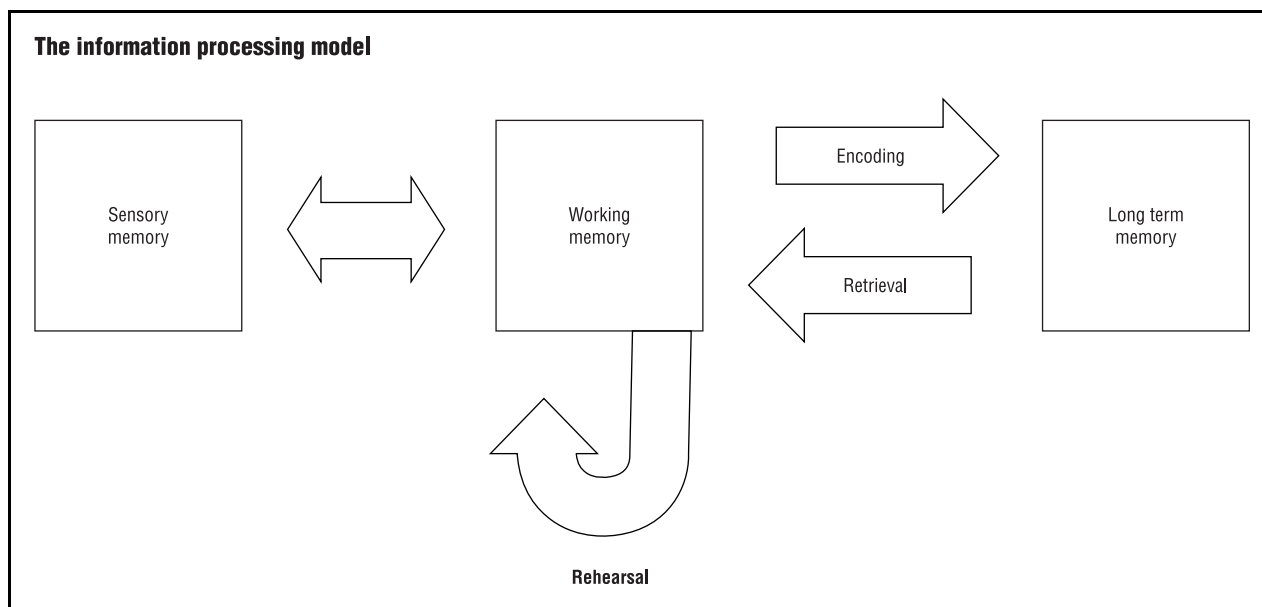

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

Several useful terms have been developed to describe efficient cognitive processing in working memory. One term is *limited attentional resources*, which refers to the highly limited nature of information processing (Anderson, 2000; Neath, 1998). All individuals experience severe limitations in how much mental activity they can engage in due to limited cognitive resources (Kane & Engle, 2002). Although humans differ with respect to available cognitive resources, all learners experience severe limitations regardless of their skill and ability level. Often, differences between one learner and another are not due to the amount of resources, but how efficiently those resources are used.

Another key term is *automaticity*, which refers to being able to perform a task very quickly and efficiently due to repeated practice (Stanovich, 2003). Automated activities usually require few cognitive resources; thus, even a complex skill such as driving a car at 75 miles per hour can seem effortless. Effective information processing in sensory memory requires a high degree of automaticity with regard to recognition of familiar stimuli such as spoken or printed words, faces, and sounds.

A third key term is *selective processing*, which refers to the act of intentionally focusing one's limited cognitive resources on stimuli that are most relevant to the task at hand. For example, when driving in snow, one might allocate more of one's limited cognitive resources to watching the center line in the highway than one would allocate on a clear summer day. In contrast, on an extremely windy day, one would pay little attention to the whereabouts of the center line but pay special attention to any flying debris

that could cause an accident. In essence, selective processing enables learners to be optimally efficient by putting all of their cognitive eggs in one basket. It is no coincidence that highly effective learners succeed because they identify what is most important to learn and allocate limited attention to relevant information.

Baddeley's 2001 model of working memory consists of three components, the *executive control system*, *articulatory loop*, and *visual-spatial sketch pad*. The role of the executive control system is to select incoming information, determine how to best process that information, construct meaning through organization and inferences, and subsequently transfer the processed information to long-term memory or choose to delete that information from the memory system altogether (e.g., a telephone number that is no longer needed). Most models of working memory assume that the central executive is the place where humans "make conscious meaning" of the information they process (Shah & Miyake, 1999). The role of the articulatory loop is to maintain and further process verbal information. The role of the visual-spatial sketch pad is analogous to the articulatory loop in that it maintains and further processes non-verbal and visual information. Information is lost quickly from working memory (i.e., 5 to 15 seconds) unless some type of mental rehearsal occurs. Barring rehearsal (e.g., repeating a telephone number), information is either forwarded to long-term memory or is deleted from the system.

Baddeley's model makes several critical assumptions about the processing of information in working memory. One is that each of the three subsystems possesses its own

A comparison of sensory, working, and long term memory			
Type of memory	Purpose	Capacity	Duration of retention
Sensory memory	Provides initial screening and processing of incoming stimuli.	3 to 7 discrete units	0.5 to 3 seconds
Working memory	Assigns meaning to stimuli and links individual pieces of information into larger units. Enables learner to construct meaning and perform visual-spatial mental operations.	7 to 9 units of information	5 to 15 seconds without rehearsal
Long term memory	Provides a permanent repository for different types knowledge	Infinite	Permanent

Table 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

pool of limited cognitive resources. This means that, under normal information processing circumstances, each subsystem performs work without taxing the other subsystems. A second assumption is that the executive control system regulates the articulatory loop and visual-spatial sketch pad.

LONG TERM MEMORY

Unlike sensory and working memory, long-term memory is not constrained by capacity or duration of attention limitations. The role of long-term memory is to provide a seemingly unlimited repository for all the facts and knowledge in memory. Most researchers believe that long-term memory is capable of holding millions of pieces of information for very long periods of time (Anderson, 2000). A great deal of research has gone into identifying two key aspects of long-term memory: (a) what types of information are represented, and (b) how information is organized. These two questions are addressed in the next section of this entry. For present purposes, there is universal agreement that qualitatively different types of information exist in long-term memory and that information must be organized, and therefore quickly accessible, to be of practical use to learners.

Figure 1 shows that working memory and long-term memory are connected by *encoding* and *retrieval* processes. Encoding refers to a large number of strategies that move information from temporary store in working memory into long-term memory. Examples include organization, inference, and elaboration strategies, which will be discussed later. Retrieval refers to processes that enable individuals to search memory and access information for active processing in working memory. Both encoding and retrieval greatly facilitate learning when information in long-term memory is organized for easy access.

A comparison of the three components of the IPM indicates that both sensory and working memory are relatively short term in nature (see Table 1). Their main roles are to screen incoming information, assign meaning, and

relate individual units of information to other units. In contrast, the main role of long-term memory is to serve as a highly organized permanent storage system. Sensory and working memory process few pieces of information within a short time frame. Automaticity of processing and selective allocation of limited cognitive resources greatly increases the efficiency of information processing. Long-term memory is assumed to be more or less permanent and unlimited in terms of capacity. The main processing constraint on long-term memory is the individual's ability to quickly encode and retrieve information using an efficient organizational system.

The information processing model provides a conceptual model which explains the different functions and constraints on human memory. The IPM also has had a major impact on instructional theory and practice. Sweller and Chandler's 1994 work developed *cognitive load theory* to explain how different instructional and learner constraints affect optimal information processing. The crux of their argument is that each task imposes some degree of cognitive load, which must be met either by available cognitive resources or learner-based strategies such as selective attention and automaticity. Reducing cognitive load enables individuals to learn with less overall mental effort. Cognitive load theory has been especially helpful in terms of planning instruction and developing learning materials. Others researchers such as Mayer and Moreno (2003) have developed frameworks to increase learning by systematically reducing cognitive load through better design of learning materials and more strategic use of limited resources by students.

In summary, the information processing model postulates a three-component model of information processing. The IPM is consistent with empirical findings and provides an excellent framework for understanding principles of effective learning, which are considered later in this entry. Sensory and working memory are limited with respect to capacity and duration, whereas long-term memory is more or less unlimited. Information processing efficiency is

increased due to automaticity and selectivity. Encoding and retrieval of information in long-term memory is increased due to efficient organizational strategies.

IMPLICATIONS FOR INSTRUCTION

The information processing model provides four important implications for improving learning and instruction. The first is that memory stores are extremely limited in both sensory and working memory. The two main strategies that effective learners use to cope with limited capacity are selectively focusing their attention on important information and engaging in as much automated processing as possible. From an educational perspective, it is essential for students to become automated at basic skills such as letter and word decoding, number recognition, and simple procedural skills such as handwriting, multiplication, and spelling. Automaticity makes available limited processing resources that can be used to engage in labor intensive self-regulation (Butler & Winne, 1995; Zeidner, Boekaerts, & Pintrich, 2000; Zimmerman, 2000) and comprehension monitoring (Schraw, 2001; Sternberg, 2001).

A second implication is that relevant prior knowledge facilitates encoding and retrieval processes. Highly effective learners possess a great deal of organized knowledge within a particular domain such as reading, mathematics, or science. They also possess general problem-solving and critical-thinking scripts that enable them to perform well across different domains. This knowledge guides information processing in sensory and working memory by providing easy-to-access retrieval structures in memory. It also serves as the basis for the development of expertise (Alexander, 2003; Ericsson, 2003). Thus, helping students use their prior knowledge when learning new information promotes learning.

A third implication is that automated information processing increases cognitive efficiency by reducing information processing demands. As discussed earlier, automaticity is an important aspect of effective learning for two reasons. One is that being automated makes it easier selectively to allocate limited resources to information that is most relevant to the task at hand. Unfortunately, there is no easy road to automaticity other than sustained, regular practice. In addition, automaticity frees limited resources that can be used for other activities such as drawing inferences and connecting new information to existing information in memory.

A fourth implication is that learning strategies improve information processing because learners are more efficient and process information at a deeper level (Pressley & Harris, 2006; Pressley & McDonald-Wharton, 1997). All effective learners draw from a repertoire of learning strategies in a flexible manner. Some of these strategies are used

automatically, while some require controlled processing and metacognitive control that place high demands on limited cognitive resources. Good learners use a wide variety of strategies and use them in a highly automatic fashion. However, there are three general strategies that all effective learners use in most situations. These include *organization*, *inferences*, and *elaboration* (Mayer & Moreno, 2003). Organization refers to how information is sorted and arranged in long-term memory. Information that is related to what one already knows is easier to encode and retrieve than isolated information. In some cases, individuals already possess well organized knowledge with empty slots that can be filled easily with new information. Activating existing knowledge prior to instruction, or providing a visual diagram of how information is organized, is one of the best ways to facilitate learning new information. Constructing inferences involves making connections between separate concepts. Elaboration refers to increasing the meaningfulness of information by connecting new information to ideas already known.

INTELLIGENCE: AN OVERVIEW

This entry covers intelligence and intelligence testing. Intelligence is a difficult and often misused concept that has had an important impact on education. The entry will first

review the definition and history of the concept of intelligence. Descriptions of the critical issues of measurement and application of the concept are then addressed. Intelligence tests commonly used in the schools are also described. Ways that tests are used in academic settings are covered with a short description of the qualifications for those who use the tests. Finally research trends and the emerging changes in the development of the concept of intelligence are addressed.

THE DEFINITIONS OF INTELLIGENCE

The specific meaning of intelligence in terms of how the concept is applied in education and schooling is difficult to convey. Everyone thinks they know intelligent performance when they see it, but when they try to define it, the elusiveness of the trait becomes apparent (Sternberg, Grigorenko, & Kidd, 2005). As Wagner (2000) has pointed out, definitions of intelligence have been notoriously inconsistent over the last century. Early definitions have tended to focus on specific or general abilities. For example, the work of Charles Spearman (1863–1945) over a century ago emphasized general ability (sometimes referred to as *g*) that involved recognition of relationships (e.g., Spearman, 1904), and intelligent activity involved combining this *g* with specific abilities. Alfred Binet (1857–1911) and Théodore Simon (1872–1961), working at around the same time, defined intelligence as “judgment, otherwise called good sense, practical sense, initiative, the faculty of adapting one’s self to circumstances. To judge well, to comprehend well, to reason well, these are the essential activities of intelligence” (Binet & Simon, 1905, p. 43). Lewis Terman (1877–1956), largely credited for bringing intelligence testing into U.S. schools and developing the first versions of the Stanford-Binet Intelligence Test, emphasized knowledge and abstract thinking in defining intelligence (Aiken, 2003; Hegarty, 2007; Terman, 1918). The definition provided by David Wechsler (1896–1981) was “The aggregate or global capacity of the individual to act purposefully, to think rationally and to deal effectively with his environment” (Wechsler, 1958, p. 7).

Most of these definitions seemed to have an orientation to academic learning and performance. More recent definitions have been moving toward practical definitions with a view toward how the person functions in the real world as well as in traditional academic settings (Wagner, 2000). For example, in their 1998 book, Eleanor Amour-Thomas and Sharon-Ann Gopaul-McNichol have suggested the importance of a relativistic definition that recognized the significance of the interaction between the biological nature of the individual and the cultural and environmental context surrounding the person. Howard Gardner conceived intelligence as “a biopsychological potential to process information in certain ways,

in order to solve problems or fashion products that are valued in a culture or community” (cited in Shearer, 2004, p. 3). Gardner saw intelligent behavior as related to specific kinds of functioning in the real world. Another of the more contemporary theorists, Robert Sternberg, defined intelligence from the perspective of research in cognitive information processing. His approach to intelligence implies successful performance in the real world and depends on an understanding of research in the ways in which the brain might work to produce intelligent behavior such as problem solving, adapting and learning. His theory is organized into three subtheories that address analytical, practical, and creative aspects of intelligent performance (Sternberg, 1994; Sternberg, Castejón, Prieto, Hautamäki, & Grigorenko, 2001). While many more definitions and approaches can be cited, they generally suggest that definitions of intelligence involve ability to learn, problem solve, and adapt. Further, later definitions move away from the notion of a unitary concept such as *g* to one that involves creativity, personal characteristics and traits, attention to the nature of the task or problem being addressed, the research on the brain and function, and environmental adaptation (Sternberg, Grigorenko, & Kidd, 2005; Sattler, 2001; Shearer, 2004).

Although many claim that intelligence is defined by what intelligence tests measure, many other theorists and researchers argue that this definition is too circular and narrow. Scores on intelligence tests are designed to reflect the definitions of intelligence rather than serve as the definition of intelligence (Gardner, Kornhaber, & Wake, 1996), or an exact and unqualified representation of intellectual ability.

BRIEF HISTORY OF INTELLIGENCE TESTING

Interest in intelligence in some form has a long history. The Greek philosopher Aristotle (384–322 BCE) studied memory, logical thought, and what knowing means well before the mid- to late 19th-century investigations of the heritability of intelligence by Francis Galton (1822–1911) took place in England. Galton, considered one of the first scientific investigators of human intelligence, devised an array of simple tests covering an assortment of mental processes involving memory, senses, and motor behavior which he administered to a large sample of people. Performance was analyzed using statistical methods. These efforts are widely considered the beginning of the mental testing movement (Brennan, 2003). Binet, who was working in France at about the same time as Galton was doing his research, was more focused on mental processes such as the ability to adapt, comprehend, and reason. The idea of public education for the masses had just taken hold and schools were compelled to deal with much more widely divergent

abilities and behavior in children than was the case with the more privileged group that had previously attended school. Binet was asked by the French Ministry of Public Instruction to help identify the children who would be successful in school and those who would not (Gardner, Kornhaber, & Wake, 1996). Binet responded with a test for this purpose (Binet & Simon, 1905).

The concept of individual differences was gaining popularity around the world at the same time as Binet’s work, spurred by the movement towards universal compulsory education in many countries. At the time, many psychologists were addressing the problem of how to identify children who would have success in education (Thorndike, 1990). In the United States, a number of psychologists, including Edward L. Thorndike (1874–1949) were addressing the problem. Thorndike, working at Teachers College of Columbia University, was central to the development of American and behavioral psychology and was very influential on American education practice (Brennan, 2003). Thorndike emphasized a neural basis of intelligence and felt that education should take advantage of natural intelligence and promote its development (Thorndike, 1990). Henry Goddard (1866–1957) translated the Binet scales and began experimenting with them. Terman standardized and normed the Binet test on California schoolchildren. He also added a concept developed by another psychologist, William Stern (1871–1938), which became the well-known Intelligence Quotient (IQ score). Originally the Binet tests yielded only a mental age, but Stern proposed dividing the mental age by the child’s chronological age and multiplying by 100. Thus a child with a mental age score of 10 years, 6 months who is 9 years, 6 months old would have an IQ of 111 (i.e., $MA/CA \times 100 = (127 \text{ months}) / (114 \text{ months}) \times 100 = 111$) (Thorndike, 1990). A child with a score of 111 would be said to be performing above other children of the same age. A child whose mental age and chronological ages were the same would have an IQ of 100 and would be considered of average intelligence for the child’s age.

Modern IQ tests use a scaling method based on the normal curve to compute the IQ score. This scaling method, known as *deviation IQ*, permits the test user to interpret a person’s IQ score in terms of the proportion of people in the normative sample that had scores above and below the person’s obtained score. This innovation was developed by Wechsler (1939) principally because the concept of mental age seemed inappropriate to use with adults. That is, intelligence tests of the time were designed with the assumption that a person’s intelligence developed until the around the age of 20, at which time mature adult intelligence had been attained. Therefore the highest mental age that could be attained on a test was 20. However, Wechsler took the view that chronological age should be a predictor of mental age. This would not be the case if chronological age was increasing while mental age was not (Thorndike, 1990).

MODERN THEORIES OF INTELLIGENCE

Early intelligence theory emerged from an emphasis on a unitary concept of general ability, as can be seen in the definitions of Binet and Spearman. Spearman created a statistical technique called factor analysis to explore his approach. From his studies with this technique, he was able to report that about half of the variance in tests of mental ability was due to the general (*g*) factor (Kaplan & Sacuzzo, 2001). The remainder was due to the special ability (e.g., numerical reasoning, vocabulary, mechanical skill) that was required of a person to enable performance of the specific tasks on the test. Later approaches tended to emphasize expanded abilities. For example, Cattell divided *g* into fluid (*gf*) and crystallized (*gc*) intelligence (Horn & Cattell, 1966; Horn & Noll, 1997). *Fluid intelligence* encompasses abilities involved in thinking, reasoning, and in learning, while *crystallized intelligence* represents the knowledge and broader understanding that has developed through learning in the environmental setting.

Other theories further recognized the diversity of intelligent performance. In his 1967 book Joy Paul Guilford (1897–1987), using factor analysis, devised a model of intelligence he termed the *Structure of Intellect* in which he proposed three aspects of intelligence: operations, products, and contents. Each of these is broken down further into specific kinds of intellectual activity which Guilford considered interrelated to produce intelligent functioning of specific tasks.

Gardner (1993) proposed a theory of multiple intelligences based on the differential cognitive processing required for demonstration of intelligent or creative performance in different areas. Gardner's theory references eight intelligences. Linguistic and logico-mathematical intelligences are most often associated with academic performance, although others could be relevant depending on the task (Shearer, 2004). Other intelligences identified by Gardner were musical, kinesthetic, spatial, naturalistic, and personal (intrapersonal and interpersonal).

Robert Sternberg also proposed a theory informed by research from cognitive psychology. Sternberg's model is named the *triarchic theory* of intelligence because it is composed of three kinds of components: memory-analytic, creative-synthetic, and practical-contextual. The first component is related to the academic view of intelligence and is most similar to what most intelligence tests measure. The second component is necessary for creative endeavors, including traditionally academic areas such as science and mathematics. Finally, the practical-contextual is necessary for success in an everyday environment like school or business (Sternberg, 1994). Daniel Golman (1995) has proposed an emotional intelligence

that bears some similarity to the personal intelligences of Gardner and the practical intelligence of Sternberg, but goes further in tying emotion and personality to the capacity for intelligent behavior. For example, fear, excitement, or anger may contribute to how one behaves regardless of one's knowledge or capacity to reason.

In the first half of the 20th century, research in intelligence was heavily influenced by factor analysis (first used by Spearman). Factor analysis is a statistical procedure that enables the systematic study of the relationships within a set of variables in order to find the common aspects. Research and theory emerging in the second half of the 20th into the 21st century has begun to have an impact on the methods of assessment of intelligence (Gardner, et al., 1996). For example, research in cognitive psychology, neuropsychology, cognitive science (Kolak, Hirstein, Mandik, & Waskan 2006), biopsychology and evolutionary processes (Geary, 2005), and cultural psychology (Armour-Thomas and Gopaul-McNicol, 1998) has begun to affect theory and research in intelligence, its measurement and applications.

MEASUREMENT OF INTELLIGENCE IN EDUCATIONAL SETTINGS

Two kinds of intelligence tests will be presented here. The first, group tests, are used to identify the range of IQ scores in a group, usually for research or administrative purposes. Group tests tend to have more specific content and question formats, and are designed for more specific purposes than individually administered tests, which aim for a relatively more comprehensive clinical picture of the individual's cognitive functioning. The individual tests are designed to provide much more information about the individual. They are only used by professionals who are trained and licensed to administer and interpret these assessment instruments as part of a comprehensive clinical assessment that contributes information useful for planning educational or therapeutic interventions. These tests provide a variety of scores and clinical information that licensed professional psychologists may use to plan interventions in schools, family, or other settings. In other words, the usefulness of individual intelligence tests goes well beyond the scores on the test. For this reason, group tests are not suitable substitutes for individual assessments when planning clinical or educational interventions.

Group Tests of Intelligence. Two examples of group intelligence test are discussed here. The Cognitive Abilities Test (Multilevel Edition, Form 6 [CogAT-6]) (Lohman 2001), and the Multidimensional Aptitude Battery, Second Edition (MAB-II) (Jackson, 1998) were chosen because they may be used in school or educational settings.

The Multidimensional Aptitude Battery-II (MAB-II) is a multiple-choice assessment of aptitude and intelligence that can be administered to groups or individuals above the age of 16. The instrument was designed to obtain scores similar to that of the individually administered Wechsler Adult Intelligence Scale-Revised (WAIS-R) in a group, as opposed to individual administration. The MAB-II produces composite scores: Verbal Scale (Information, Comprehension, Arithmetic, Similarities, Vocabulary), Performance Scale (Digit Symbol, Picture Completion, Spatial, Picture Arrangement, and Object Assembly) and Full Scale. The test can be pencil and paper or computer-administered.

The MAB-II is considered to be a useful tool for assessing cognitive abilities when large numbers of students must be screened. It is a well-developed and empirically sound instrument that provides correlations between subtest scores and occupational strengths (Thompson, 2003). The test can be administered by a proctor, rather than by a post-master's-level professional. As a result, the MAB-II should not be used for making clinical diagnoses about intelligence (Widaman, 2003). Additionally, MAB-II should not be administered to students with a learning disability related to reading comprehension or whose reading level is below ninth grade because the test relies on the test-takers' reading ability (Thompson, 2003).

The Cognitive Abilities Test Multilevel Edition, Form 6 (CogAT-6) is one of the more widely used group ability tests for students in kindergarten through 12th grades. The test is intended to guide instruction to match the cognitive abilities and needs of each student, to provide an "alternative" measure of cognitive development, and to identify achievement-ability discrepancies. The test has a multitheoretical foundation as it is based on Vernon's model of hierarchical abilities, Cattell's model of crystallized and fluid abilities, and Carroll's work specifically on general abstract reasoning. The CogAT-6 is composed of two editions: the Primary and Multilevel Editions, both of which are intended to assess reasoning and problem-solving abilities and can be broken down into Verbal, Nonverbal, and Quantitative Batteries. The Primary Edition is designed for students in K-2nd grade and consists of six subtests. The Multilevel Edition is a nine-subtest instrument that is based on the Lorge-Thorndike Intelligence Tests (Lorge & Thorndike, 1954) and is appropriate for students in 3rd to 12th grade. The CogAT-6 has a mean of 100 and standard deviation of 16.

DiPerna's 2005 review of the CogAT-6 suggested that the strengths of the test include a large, representative standardization sample, co-norming with the Iowa Tests, and a theoretical basis. In spite of these positive attributes, significant weaknesses were cited relative to the CogAT's purposes as described earlier. Criticisms included insuffi-

cient empirical evidence to support basing instructional recommendations on test results, a lack of reliability and predictive validity to measure cognitive ability and to predict cognitive ability-achievement discrepancies.

Individual Intelligence Tests. The following individual intelligence tests will be reviewed:

- Wechsler Intelligence Scale for Children-IV (WISC-IV)
- Woodcock-Johnson Tests of Cognitive Abilities-III (WJ COG III)
- Stanford-Binet Intelligence Scales, Fifth Edition (SB5)
- Das-Naglieri Cognitive Assessment System (CAS)
- Kaufman Assessment Battery for Children (K-ABC)

The Wechsler scales continue to be the most widely utilized individually administered tests of intelligence (Flanagan & Kaufman, 2004). As previously discussed, the Wechsler tests are based on the *g* factor or the "overall capacity of the individual to act purposefully, to think rationally, and to deal effectively with the environment" (Sternberg, 2000, p. 481). The Wechsler Intelligence Scale for Children, Fourth Edition (WISC-IV) is the current revision of the Wechsler scales for children 6.0 to 16.11 years of age. The WISC-IV comprises 15 subtests (5 of which are supplemental). Scores on these tasks contribute to the four composite indices (Verbal Comprehension, Perceptual Reasoning, Working Memory, and Processing Speed) in addition to a Full Scale IQ (FSIQ) score that can range from 40 (very low) to 160 (very high), with a mean of 100 representing the average score, and a standard deviation of 15. A profile of the test taker's learning strengths and weaknesses are derived from the test performance. The FSIQ is derived from a combination of all subtest scores and is considered the most representative estimate of global intellectual functioning. However, when large discrepancies between Index scores exist, the FSIQ can be invalid and misleading. In this case, it is most helpful to describe the strengths and weaknesses in the profile and de-emphasize the FSIQ.

The WISC-IV continues to be a reliable and valid instrument. WISC-IV scores can be interpreted in combination with Wechsler Individual Achievement Test, Second Edition (WIAT-II) scores for comparisons between ability and achievement. Flanagan and Kaufman (2004) provide an extensive description of the strengths and limitations of this assessment tool. They cite the WISC-IV's most significant strengths as being "a robust four-factor structure across the age range of the test, increased developmental appropriateness, de-emphasis on time, improved psychometric properties, and an exemplary standardization sample (p. 171)." Flanagan & Kaufman (2004) indicate that none of the

WISC-IV's limitations are very serious, although they suggest ways in which its validity could be improved.

Other Wechsler scales have been developed to assess IQ for young children and adults. The Wechsler Preschool and Primary Scale of Intelligence, Third Edition (WPPSI-III) (Harcourt Assessment, 2002) can be administered to children 2.6–7.3 years old and the Wechsler and the Wechsler Adult Intelligence Scale, Third Edition (WAIS-III) (Harcourt Assessment, 1997) is given to adults between 16 and 89 years of age.

The Woodcock-Johnson Tests of Cognitive Abilities-III (WJ COG III) is also widely used instrument in school settings. The WJ COG III is often administered as the examiner's second choice, if the age-appropriate Wechsler scale has been administered less than three years from the current assessment date. The WJ COG III is based on Catell, Horn, and Carroll's (CHC) concept of intelligence (Reynolds, Keith, Fine, Fisher & Low 2007). The WJ COG III has been normed on individuals age 2 through 90+. The standard battery includes 10 tests, while the extended battery consists of 20. Based on these scores, the examinee earns three Cluster Scores (Verbal Ability, Thinking Ability, and Cognitive Efficiency) and a General Intellectual Ability (GIA) score. Test scores in the standard and extended batteries are not weighted equally when the GIA score is computed.

The WJ COG III has high technical quality and is based on a well-respected theory of cognitive abilities (Schrank, Flanagan, Woodcock, & Mascolo, 2002). It assesses cognitive abilities for a wide age range and uses sophisticated scoring procedures to calculate scores and discrepancies (Sattler, 2001). Additionally, ability and achievement discrepancy norms are provided as the WJ COG III was co-normed with the Woodcock Johnson Tests of Achievement, Third Edition (WJ ACH III). Greater evidence is necessary to understand the utility of the clinical clusters (Schrank, Flanagan, Woodcock, & Mascolo, 2002). The WJ COG III may also overestimate abilities if interpreted incorrectly. For example, the Written Language test score emphasizes one's ability to write brief sentences rather than to develop and organize paragraphs.

The Stanford-Binet Intelligence Scales, Fifth Edition (SB5), a direct descendent of Terman's adaptation of the Binet test developed more than 100 years ago, is used occasionally in the educational setting. The SB5 is based on the CHC theory of intelligence. It is designed for assessing intelligence and cognitive abilities among individuals between the ages of 2 and 85+. The SB5 consists of ten subtests and these scores are used to calculate four composite scores: factor, domain, abbreviated, and full scale (score range 40–160, mean = 100, SD = 15). The five factors measured include Fluid Reasoning, Knowledge, Quantitative Reasoning, Visual-Spatial Reasoning, and

Working Memory, each with verbal and nonverbal components. The SB5 contains two domain scales: Nonverbal IQ (NVIQ) and Verbal IQ (VIQ). An Abbreviated Battery IQ (ABIQ) can be determined with two routing subtest scores and the Full Scale IQ (FSIQ) is calculated using all 10 subtests.

The SB5 is advantageous as it emphasizes both verbal and nonverbal abilities. The instrument is technically sound, according to Johnson and D'Amato (2005), although Kush's 2005 study cites technical limitations (e.g., lower stability for young children and individuals with low cognitive abilities, problematically high correlations with achievement, uncertain factor structure). In spite of these weaknesses, the SB5 is referred to as an outstanding measurement instrument for the assessment of cognitive abilities of children, adolescents, and adults (Johnson & D'Amato, 2005; Kush, 2005).

The Das-Naglieri Cognitive Abilities System (CAS) is a tool based on Luria's cognitive processing model that is intermittently used to evaluate cognitive abilities in schools. The CAS is useful for assessing Planning, Attention, Simultaneous, and Successive (PASS) abilities among students between the ages of 5.0 and 17.11. The instrument's basic battery comprises 8 subtests and the standard battery consists of 12 subtests.

The CAS is an innovative instrument and its development meets high standards of technical adequacy (Meikamp, 2003). When compared to other individually administered general ability tests, it takes less time to administer (Thompson, 2003). Additional empirical research must be completed to support the PASS construct. Factor analyses of subtests support both a 4-factor PASS model as well as a 3-factor model, which suggests that Planning and Attention may or may not be separate factors. (Thompson, 2003).

The Kaufman Assessment Battery for Children, Second Edition (KABC-II) is occasionally utilized in schools as a culture-fair assessment of cognitive abilities for students between the ages of 3 and 18. The KABC-II is based on a dual theoretical framework, Luria's neuropsychological model (Naglieri, 1998) and the CHC approach. The authors suggest that its multitheoretical base allows the examiner to select which model is most appropriate for interpretation of results depending on the culture and/or verbal skills of the examinee. This assessment instrument contains 20 subtests that contribute to 4 scale scores (Sequential Processing, Simultaneous Processing, Planning, Learning, and Knowledge). The KABC-II has a mean of 100 and standard deviation of 15.

The KABC-II is an acceptable option for measuring cognitive abilities as it provides a reasonable, well-normed, clinically appealing, and technically sound approach to measuring cognitive abilities and generating diagnoses (Braden, 2005). Other strengths of the KABC-II include

smaller score discrepancies between ethnic groups and the ability to compare ability and achievement differences with the Kaufman Test of Educational Achievement, Second Edition, Comprehensive Form. However, it has been criticized for the suggestion that examiners can select the model (Luria or CHC) by which to interpret results. Braden (2005) and Thorndike (2005) suggest that the interchangeability of theoretical models is inappropriate and illogical.

Intelligence testing should not be conducted in a vacuum. In addition to using previously mentioned norm-referenced tests, an assessment should include a variety of other data from a multitude of informants. Sattler (2001) suggests that norm-referenced testing should be accompanied by interviews with a parent, teacher, and student; observations of the student during both the formal testing and natural environment (e.g., classroom, lunchroom, playground); and informal assessment procedures (e.g., district-wide criterion-referenced tests, school records). Such an assessment will provide the most accurate information by which educators can most effectively serve the student.

Group versus Individual Intelligence Tests. Whereas group-administered IQ tests can be very well constructed (Aiken 2003) and can provide valid and reliable information suitable for certain non-clinical applications, they do not provide the same kind of information as individual tests and should not be used for the same purposes. One reason is that group tests primarily emphasize multiple-choice question format, whereas individually administered tests provide a variety of response formats across the test. This allows clinicians to gather considerable clinically useful information about the person being tested, such as the approaches used in problem solving, quality of verbal expression, and other observational data (Domino 2000; Sattler 2001). Group tests were not designed to be used for clinical purposes and therefore should not be utilized in clinical settings or to substitute for individually administered intelligence tests for designing clinical interventions or individual educational programs (IEPs) in school settings.

Individual intelligence tests are designed to be administered by highly trained professionals who interpret data through the lens of learning, cognition, emotion, language, culture, health, and development. The one-on-one setting provides advantages to the test-taker and the examiner. First, it allows the examiner to develop rapport with the test-taker, which can benefit the shy or anxious test-taker. Second, the examiner has the opportunity to observe important test-taking behavior such as impulsiveness, compulsiveness, confidence, anxiety, and wandering attention, which may vary according to the task and contribute to the interpretation of the performance on the test. Third, the examiner can observe specific

problem-solving approaches, which may also vary with the task. The integration of these observations with test scores allows the examiner to take a holistic approach in interpreting scores and developing interventions.

APPLICATIONS IN CLASSROOMS AND SCHOOLS

Individual intelligence tests are used in schools and other educational settings to provide information about children's and adolescents' ability to express themselves, reason and problem solve, and perform on a variety of tasks. This information can be used to design programs for children with special needs or gifts in academic areas. Despite their shortcomings, intelligence tests are considered useful for identifying children for advanced programs for gifted learners (Pyryt, 1996). These tests also play an especially important role in special education. They can be useful for identifying an expected level of academic performance and also in helping school professionals design individual educational programs (IEP) for students with special needs (Sattler, 2001). However, Kim (2005) found in a meta-analysis of 21 studies that IQ tests are not effective for use in identifying students with special talents.

RESEARCH TRENDS

Research in intelligence is active and robust, and this section surveys the spectrum of investigations of intelligence related to school learning and performance. One active area of research is on the tests of intelligence themselves. Specifically, confirmatory factor analysis, a procedure for statistically examining the fit of data from a test to a hypothesized model, is being increasingly utilized to determine whether the theories and models of intelligence underlying tests is verifiable from performance on the test. For example, confirmatory factor analysis was used to verify the structure of the Kaufman Assessment Battery for Children, Second Edition, and the fit of the performance data to the Cattell-Horn-Carroll model of intelligence (Reynolds, Keith, Fine, Fisher, & Low, 2007). The technique was also used successfully to verify the factor structure of Sternberg's Triarchic Abilities Test Level-H (STAT) (Sternberg, Castejón, Prieto, Hautamäki, & Grigorenk, 2001). A related collection of research is directed at investigating the underlying theories and models of intelligence that have been proposed. Most of this research bases hypotheses and research questions on recent research in fields such as cognitive science, neuroscience, emotion, cultural psychology. An example of this kind of research is provided by Visser and her colleagues. Their research compared performance on tests of the components of Gardner's multiple intelligence theory with people's estimates of

their own ability and found only modest significant relationships between estimated and measured abilities, and that people tended to overestimate their abilities (Visser, Ashton, & Vernon, 2008).

Research has shown that IQ scores seem to be trending upward (Flynn, 1984). The research has moved from documentation of the phenomenon across countries and cultures (Flynn, 1987; Daley, Whaley, Sigman, Espinosa, & Neumann, 2003), into investigations of whether people are truly becoming more intelligent or whether other explanations seem more plausible in explaining the phenomenon (Rodgers & Wänström, 2007). Some evidence has been provided that increase in measured IQ seems more related to areas considered more reflective of fluid rather than crystallized intelligence performance, such as mathematics test performance (Dickens & Flynn, 2001; Rodgers & Wänström, 2007).

The importance of cultural context in relation to intelligence cannot be minimized (Benson, 2003; Sternberg, 2004). The early definitions of intelligence were tied directly to school performance but have become more encompassing to include culture, language, social class, and related issues. For example, Sternberg's definition emphasizes success in life (Sternberg, 2004). However, a difficulty emerges in determining the standard criteria to use for this kind of intelligence (Benson, 2003). In primitive society, success might be simply be survival. Traditional IQ tests have long been considered culturally unfair because diverse groups such as those of Hispanic origin, African Americans, and Native Americans have not scored as well on them as White groups (Dickens & Flynn, 2006; Rushton & Jensen, 2006; Sternberg, Grigorenko, & Kidd, 2005). The discrepancy between Black and White Americans' test performance has been used to suggest a genetic determinant of IQ, a view has been attacked as unscientific and simplistic (Cooper, 2005; Cronshaw, Hamilton, Onyura & Wilson, 2006; Sternberg, Grigorenko, & Kidd, 2005). Recent research has shown the gap between Whites and Blacks narrowing (Dickens & Flynn, 2006).

The relationship between intelligence test performance and academic performance is well documented (Brody, 1997; Haywood, 2004; Sattler, 2001). Gagne and St. Pére (2002) found no significant relationship between motivation and IQ scores, and that IQ scores seemed to be even more related to achievement than motivation scores. Other studies have revealed strong relationship between IQ and academic performance. For example, in their 2007 study, Lynn and Mikk found significant relationships between IQ and academic performance in math and science among 10-year-olds in 25 countries and 14-year-olds in 46 countries. Barber (2005) reported significant relationships between literacy and having completed secondary education (among other variables) in 81 countries. Considerable research

suggests that one of the factors underlying the relationship between IQ and performance in academic subjects is mental processing speed (Luo, Thompson & Detterman, 2003). Sheppard's 2008 review of 172 studies of intelligence and the speed of information processing concluded that measures of intelligence and speed of mental processing are highly correlated, and males and females are faster on different types of speeded tasks.

This brief summary of the research relevant to theory and practice in intelligence shows that the field is active and dynamic. Also, it should be evident that intelligence researchers of the 21st century are addressing a broader, more complete concept of intelligence than was evident in the previous century. As related research in biology of the mind, emotion, neuropsychology, family dynamics, and cognitive processing progresses to new findings, these results will be incorporated into increasingly useful models and theories of the workings of intelligence and how to assess them.

Intelligence has been a useful concept for planning education for over a century. It is a difficult concept to define. Aspects of the definition that seem to have wide appeal include learning speed, adaptability, and ability to perform successfully. Group intelligence tests can be useful in research, or for assessing groups of students. They are not useful as a replacement for individual intelligence tests administered by qualified examiners in assessing for individual clinical or educational intervention. The Wechsler tests are among the most widely used instruments for assessing intelligence. Further, IQ score is a necessarily incomplete reflection of intelligence. It is far from perfect as an index of a person's total intellectual ability and is not useful in identifying specific talents. Cognitive and brain research has begun to impact theories of intelligence in important ways. Other areas that have impacted the field of intelligence are language, culture, biology, and the neurosciences. Recent theories of intelligence are emphasizing more than one unitary ability.

INTELLIGENCE TESTING

Intelligence and intelligence testing are two of the most controversial and highly polemic of all topics in the field of psychology. It seems that psychologists, educators, and indeed, the lay public alike, all have a love-hate relationship with the concept of intelligence and even more so with intelligence testing. Some form of intelligence test-

ing is one of the most widely used of all forms of psychological tests. While tests for special aptitudes are available, and these are widely used for specialized diagnostic purposes as well as specialized aspects of personnel selection, these tests all measure some aspect of intellectual function. This entry describes more generally intelligence testing, provides a brief history of intelligence tests, presents their fundamental assumptions, applications, and an introduction to their interpretation.

INTELLIGENCE AND ACHIEVEMENT

Achievement tests as those designed to assess students' knowledge or skills in a content domain in which they have received instruction. In contrast, intelligence tests are broader in scope than achievement tests and are designed to measure the cognitive skills, abilities, and knowledge that individuals have accumulated as the result of their overall life experiences coupled with skills in application of these attributes to problem-solving. In other words, while achievement tests are tied to a specific program of instruction, intelligence tests reflect the cumulative impact of life experiences as a whole in concert with an individual's underlying or latent ability to use information. The general intelligence factor, *g*, is the most reliable component present in any multifactorial view of intelligence (Jensen, 1998). In the Cattell-Horn model (Horn & Cattell, 1966; Kamphaus, 2001) of intelligence, *g* is the dominant factor in the hierarchy of multiple abilities, with the next two dominant facets being crystallized and fluid intelligence.

Crystallized intelligence tends to be related more closely to verbal domains as a practical matter and is defined as the application of knowledge to problem solving. Fluid intelligence tends to be related more closely to non-verbal domains as a practical matter and is defined more strictly as reasoning and problem solving in the absence of any requirement for prior knowledge. It turns out that people do not really know how to assess reasoning and problem solving in the total absence of knowledge and so most tests of fluid intelligence attempt to approximate this perfect state to the extent possible by using principally nonverbal tasks that do not require knowledge of language or language concepts (Reynolds & Kamphaus, 2003).

The inclusion of crystallized intelligence measures as a component of most intelligence tests has led many people to believe, erroneously, that intelligence tests are simply measures of what people have learned. While intelligence and knowledge are certainly correlated, intelligence as measured on modern individually administered tests of intelligence and even many group measures is more directed at the assessment of problem solving and reasoning skill as opposed to static knowledge or learned

content. The latter is the domain of achievement testing (Reynolds, Livingston, & Willson, 2006).

This introduction might suggest that there is a clear and universally accepted distinction between achievement and intelligence tests. However, in actual practice such is not the case and the distinction is actually a matter of degree. Many, if not most, testing experts conceptualize both achievement and intelligence tests as tests of developed cognitive abilities that can be ordered along a continuum in terms of how closely linked the assessed abilities are to specific learning experiences. The abilities measured by achievement tests are specifically linked to academic instruction or training. In contrast, the knowledge and abilities measured by intelligence tests are acquired through a broad-range of life experiences, including those at school, home, work, and all other settings.

General intelligence tests historically have been the most popular and widely used aptitude tests in school settings. While many people are familiar with the concept of intelligence and use the term in everyday conversations, it is not easy to develop a definition of intelligence on which everyone agrees. While many people, lay or professional, will have their own separate definition of intelligence, most of these definitions will incorporate abilities such as problem solving, abstract reasoning, and the ability to acquire knowledge. Developing a consensus beyond this point has proved quite difficult.

THE ORIGIN OF INTELLIGENCE TESTS

Intelligence tests had their beginning in the schools, in the early 1900s in France when a compulsory education program was initiated. Alfred Binet (1857–1911) and his colleague Theodore Simon (1873–1961) had been attempting to develop a measure of intelligence for some years and were commissioned by the French government to develop a test that could predict academic performance accurately. The result of their efforts was the first Binet-Simon Scale released in 1905. This test contained problems arranged in the order of their difficulty and assessing a wide range of abilities. The test contained some sensory-perceptual tests, but the emphasis was on verbal items assessing comprehension, reasoning, and judgment. Subsequent revisions of the Binet-Simon Scale were released in 1908 and 1911. These scales gained wide acceptance in France and were soon translated and standardized in the United States by Louis Terman (d. 1959) at Stanford University. Terman's work resulted in the Stanford-Binet Intelligence Test (1916), which has been revised numerous times and continues to be a prominent intelligence test used in the early 2000s.

The introduction of the Stanford Binet intelligence scales in the United States by Terman occurred in close proximity to World War I. Seeing the success of this

approach to measuring mental ability, the U.S. Army set about to devise a means of evaluating recruits. A group of psychologists headed by Robert Yerkes (1876–1956) subsequently developed the Army Alpha and Army Beta examinations, which quickly became the most widely used group intelligence tests in the world. This widespread use also had the effect of familiarizing literally millions of individuals with the concept of intelligence testing and made it an acceptable enterprise. Not long afterward, the College Entrance Examination Board began development and employment of what became the SAT, a conglomerated measure of achievement and intelligence.

The development and success of the Binet-Simon Scale, and subsequently the Stanford-Binet Intelligence Test and the U.S. Army testing programs, ushered in the era of widespread intelligence testing in the United States. Following the model of the Stanford-Binet Intelligence Test, other assessment experts developed and released their own intelligence tests. Some of the tests were designed for individual administration (such as the Stanford-Binet Intelligence Test) while others were designed for group administration. Some of these tests placed more emphasis on verbal and quantitative abilities while others placed more emphasis on visual-spatial and/or abstract problem-solving abilities. As a general rule, research has shown with considerable consistency that contemporary intelligence tests are good predictors of academic success. This correlation is to be expected considering this was the precise purpose for which they were initially developed over 100 years earlier. In addition to being good predictors of school performance, research showed that IQs are fairly stable over time. Nevertheless, these tests became controversial as a result of the often-emotional debate over the meaning of intelligence. To try and avoid this association and possible misinterpretations, many test publishers adopted more neutral names such as “academic potential,” “scholastic ability,” “school ability,” “mental ability,” or simply “ability” to designate essentially the same construct to which the term intelligence referred.

THE USE OF APTITUDE AND INTELLIGENCE TESTS IN SCHOOLS

Clearly, aptitude and intelligence tests have a long history of use in the schools. Their widespread use continues in the early 2000s, with major applications including the following (Reynolds et al., 2006; Reynolds & Kamphaus, 2003):

Providing alternative measures of cognitive abilities that reflect information not captured by standard achievement tests or school grades,

Providing objective evaluations of ability that do not reflect the subjective judgment of observers or others who may be influenced by irrelevant factors,

Helping teachers tailor instruction to meet a student's unique pattern of cognitive strengths and weaknesses,

Assessing how well students are prepared to profit from school experiences,

Identifying students who are underachieving and may need further assessment to rule-out learning disabilities or other cognitive disorders, including mental retardation or intellectual disability,

Identifying students for gifted and talented programs,

Helping guide parents and students with educational and vocational planning.

While this list identifies the most common uses of aptitude/intelligence tests in the schools, the list is not exhaustive. Classroom teachers and school administrators are involved to varying degrees with these applications. For example, teachers are frequently called on to administer and interpret many of the group aptitude tests for their own students. School psychologists or other professionals with specific training in administering and interpreting clinical and diagnostic tests typically administer and interpret the individual intelligence and aptitude tests.

COMMON INDIVIDUALLY ADMINISTERED TESTS OF INTELLIGENCE

As with achievement tests, group and individual intelligence tests are commonly used in schools. Whereas teachers are often asked to help administer and interpret the group aptitude tests, school psychologists and other professionals with special training in administering and interpreting clinical and diagnostic tests usually administer and interpret the individual tests. The most frequently employed individually administered intelligence tests are reviewed briefly below.

Wechsler Intelligence Scale for Children, Fourth Edition (WISC-IV). The WISC-IV is as of 2007 the most popular individual test of intellectual ability for children. Empirical surveys of school psychologists and other assessment personnel have consistently shown that the Wechsler scales are the most popular individual intelligence test used in clinical and school settings with children. The WISC-IV, as is true of virtually all individually administered intelligence tests, must be administered by professionals with extensive training in psychological assessment. The WISC-IV is one of the

longest of such intellectual assessments and takes approximately 2 to 3 hours to administer and score. Below are brief descriptions of the subtests (Wechsler, 2003):

Arithmetic the student is presented a set of arithmetic problems that they solve mentally (i.e., no pencil and paper) and answer orally. This subtest involves numerical reasoning ability, mental manipulation, concentration, and auditory memory.

Block Design the student reproduces a series of geometric patterns using red-and-white blocks. This subtest measures the ability to analyze and synthesize abstract visual stimuli, nonverbal concept formation, and perceptual organization.

Cancellation the student scans sequences of visual stimuli and marks target forms. This subtest involves processing speed, visual attention, and vigilance.

Coding the student matches and copies symbols that are associated with either objects (i.e., Coding A) or numbers (Coding B). This subtest is a measure of processing speed, short-term visual memory, mental flexibility, attention, and motivation.

Comprehension the student responds to questions that are presented orally involving everyday problems or social situations. This subtest is a measure of verbal comprehension and reasoning as well as the ability to apply practical information.

Digit Span the student is presented orally sequences of numbers that they repeat verbatim (i.e., Digits Forward) or in reverse order (i.e., Digits Backwards). This subtest involves short-term auditory memory, attention, and on Digits Backwards, mental manipulation.

Information the student responds to questions that are presented orally involving a broad range of knowledge (e.g., science, history, and geography). This subtest measures the student's general fund of knowledge.

Letter-Number Sequencing the student reads a list of letters and numbers and then recalls the letters in alphabetical order and the numbers in numerical order. This subtest involves short-term memory, sequencing, mental manipulation, and attention.

Matrix Reasoning the student examines an incomplete matrix and then selects the item that correctly completes the matrix. This subtest is a measure of fluid intelligence and is considered a

largely language-free and culture-fair measure of intelligence.

Picture Completion the student is presented a set of pictures and must identify what important part is missing. This subtest measures visual scanning and organization as well as attention to essential details.

Picture Concepts the student examines rows of objects and then selects objects that go together based on an underlying concept. This subtest involves nonverbal abstract reasoning and categorization.

Similarities two words are presented orally to the student and the student must identify how they are similar. This subtest measures verbal comprehension, reasoning, and concept formation.

Symbol Search the student scans groups of symbols and indicates if a target symbol is present. This subtest is a measure of processing speed, visual scanning, and concentration.

Vocabulary the student is presented orally a series of words that the student must define. This subtest is primarily a measure of word knowledge and verbal conceptualization.

Word Reasoning the student must identify the underlying or common concept that is implied by a series of clues. This subtest involves verbal comprehension, abstraction, and reasoning.

Information, Word Reasoning, Picture Completion, Arithmetic, and Cancellation are supplemental subtests while the other subtests are core subtests. The administration of supplemental subtests is not mandatory, but they may be used to substitute for a core subtest if the core subtest is seen as being inappropriate for a particular student (e.g., due to physical limitation). A supplemental subtest may also be used if a core subtest is invalidated for some reason (e.g., its administration is interrupted).

The WISC-IV produces four Index Scores. Below are brief descriptions of the Index Scores (Wechsler, 2003):

Verbal Comprehension Index (VCI) is a composite of Similarities, Vocabulary, and Comprehension. Information and Word Reasoning are supplemental VCI subtests. The VCI reflects verbal reasoning, verbal conceptualization, and knowledge of facts.

Perceptual Reasoning Index (PRI) is a composite of Block Design, Picture Concepts, and Matrix Reasoning. Picture Completion is a supplemental PRI subtest. The PRI reflects perceptual and

nonverbal reasoning, spatial processing abilities, and visual-spatial-motor integration.

Working Memory Index (WMI) is a composite of Digit Span and Letter-Number Sequencing. Arithmetic is a supplemental WMI subtest. The WMI reflects the student's working memory capacity that includes attention, concentration, and mental control.

Processing Speed (PSI) is a composite of Coding and Symbol Search. Cancellation is a supplemental PSI subtest. The PSI reflects the student's ability to quickly process nonverbal material as well as attention and visual-motor coordination.

The WISC-IV and its predecessors are designed for use with children between the ages of 6 and 16 years of age. For early childhood assessment the Wechsler Preschool and Primary Scale of Intelligence, Third Edition (WPPSI-III) is available and is appropriate for children between 2 years 6 months to 7 years 3 months. The Wechsler Adult Intelligence Scale, Third Edition (WAIS-III) is appropriate for individuals between the ages of 16 and 89 years of age.

Stanford-Binet Intelligence Scales, Fifth Edition (SB5). The Stanford-Binet Intelligence Test was the first intelligence test to gain widespread acceptance in the United States. While the Wechsler scales have become the most popular and widely used intelligence tests in schools, the Stanford-Binet scales have continued to have a strong following. As of 2007, the most recent edition of these scales is the SB5 that was released in 2003. The SB5 is designed for use with individuals from 2 to 85 years of age. It contains 10 subtests which are combined to produce five factor indices (i.e., Fluid Reasoning, Knowledge, Quantitative Reasoning, Visual-Spatial Processing, and Working memory), two domain scores (i.e., Verbal IQ

Example of a common set of qualitative descriptions of performance levels expressed as IQs

Score level	Qualitative description	Approximate percent of population included
69≤	Significantly below average	2.34
70–79	Moderately Below average	6.87
80–89	Below average	16.12
90–109	Average	49.61
110–119	Above average	16.12
120–129	Moderately above average	6.87
≥130	Significantly above average	2.34

Table 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

and Nonverbal IQ), and a Full Scale IQ reflecting overall intellectual ability. A potentially appealing aspect of the SB5 is the availability of an Extended IQ scale that allows the calculation of FSIQs higher than 160, which can be useful in the assessment of extremely gifted individuals.

Woodcock-Johnson III (WJ III) Tests of Cognitive Ability. The WJ III Tests of Cognitive Ability has gained a loyal following and has some unique qualities that warrant mentioning. The battery is designed for use with individuals 2 to 90 years of age. The WJ III Tests of Cognitive Ability is based on the Cattell-Horn-Carroll (CHC) theory of cognitive abilities, which incorporates Cattell's and Horn's Gf-Gc theory and Carroll's three-stratum theory. The CHC model provides a comprehensive model for assessing a broad range of cognitive abilities, and many clinicians like this battery because it measures such a broad range of abilities.

Reynolds Intellectual Assessment Scales (RIAS). The RIAS is a newcomer to the clinician's collection of intelligence tests. It is designed for use with individuals between 3 and 94 years of age and incorporates a co-normed supplemental memory test. One particularly desirable aspect of the RIAS is the ability to obtain a reliable and valid measure of intellectual ability that incorporates both verbal and nonverbal abilities (crystallized and fluid intelligence) in a relatively brief period (i.e., 20–25 minutes). Most other tests that assess verbal and nonverbal cognitive abilities require considerably more time. The supplemental memory tests require about 10 minutes for administration, so a clinician can assess both memory and intelligence in approximately 30 minutes.

INTELLIGENCE TEST SCORES

In the early decades of intelligence testing, intelligence test scores were expressed as a true quotient, hence the term IQ or intelligence quotient. An IQ was defined as a ratio of the examinee's mental age to the examinee's chronological age which was then multiplied by 100 to eliminate dealing with fractional scores $[(MA/CA) \times 100]$. This form calculation of an IQ has serious psychometric and related measurement problems and has been abandoned for decades although its presentation continues to be common in many introductory psychology and education textbooks. In the early 2000s, IQs are calculated in the form of age corrected deviation scaled scores. These are formal transformations of raw scores (i.e., number of points obtained or items answered correctly) into a standard score format that incorporates the use of the mean and the standard deviation of the raw scores at predetermined age intervals so that the IQ given by the test has the same percentile ranking at each age level, which is not true of the old ratio style IQ. Table 1 presents a common system for ascribing a qualitative descriptor to various score ranges found on most common

intelligence tests, nearly all of which (including all of those reviewed above) report IQs using a metric where the mean IQ is equal to 100 and the standard deviation is 15. When accompanied by significant deficits and adaptive behavior and occurring during the developmental period, scores below 70 are commonly associated with varying degrees of mental retardation or intellectual disability, while scores above 130 are often used to designate individuals as being intellectually talented or cognitively gifted.

The scores from intelligence tests are derived from large samples of individuals drawn using what is known as population proportion of stratified random sampling. Because all individuals in the United States cannot be tested, a sample is drawn to represent the entire population. This sample is typically chosen to be representative of the general population of the United States at large on the basis of gender, ethnicity, social economic status or educational level, region of residence within the United States, and community size, including urban and rural areas.

Scores from intelligence tests are interpreted properly only when the standardized instructions for administering and scoring the test have been followed rigidly. Deviations from standardized administration and scoring cause the scores to move up or down for an individual examinee inappropriately and in ways that are unpredictable, rendering the scores uninterpretable (Lee, Reynolds, & Willson, 2003). Intelligence test scores are viewed by some as reflecting innate potential but clearly that is not the case. While innate ability contributes to intelligence test performance, many other variables contribute to performance on ability measures as well.

Intelligence as measured on such tests as described here is a summative construct at any given point that is a reflection not only of a person's innate potential but the interaction of this potential with the entire life experiences of the individual as well as factors such as early stimulation, nutrition, prenatal care, and numerous other variables too extensive to list and discuss here. Proper interpretation of intelligence tests requires knowledge of the examinee's history, background, educational exposure, and generally the context of the examinee's life, especially when clinical diagnoses are being considered. Intelligence tests in the schools are very good predictors of academic achievement, but even this prediction is predicated upon averages among the various examinees. This qualification means that intelligence tests' predictions of future attainment are based on various assumptions about individuals taking such tests. Such assumptions, for example, would include the assumption that a particular examinee is no more motivated to achieve than the average person taking the test, that such an examinee would spend no more and no less time studying in any particular academic area, and would have no more or

Interest

no less opportunity to acquire information in a particular academic domain. To the extent such assumptions are violated, the predictive schema of the intelligence test score interpretation would not hold.

INTEREST

Researchers have identified two types of interest. Situational interest is spontaneous, transitory, and environmentally activated, whereas personal interest, also referred to as individual interest, is less spontaneous, of enduring personal value, and activated internally. Situational interest often precedes and facilitates the development of personal interest. Situational interest appears to be especially important in catching students' attention, whereas personal interest may be more important in holding it (Durik & Harackiewicz, 2007; Mitchell, 1993). Personal interest appears to be especially important for sustaining engagement and long-term learning (Hidi & Renninger, 2006).

Situational interest increases learning when the task or to-be-learned information is novel or when information is relevant to a task or learning goal. Text variables such as coherence, identification with characters, suspense, and the concreteness and image-ability of salient text segments also increase situational interest. Collectively, these variables can explain over 50 percent of sample variance in students' learning from text (Schraw, 1997).

Personal interest increases learning due to increased engagement, the acquisition of expert knowledge, and making mundane tasks more challenging. Personal interest

is also important because it appears to mediate the relationship between short-term situational interest and long-term mastery and learning within a domain (Hidi & Renninger, 2006). In addition, several studies suggest that personal interest increases the amount and quality of information processing. For example, Schiefele (1999) found that readers with personal interest in a topic were more likely to engage in deeper text processing, characterized by the construction of situational models (i.e., a mental representation of the people, setting, and events implied by the text).

CATCHING AND HOLDING INTEREST

Mitchell (1993) suggested that personal interest develops over time because some topic or event catches an individual's interest in a situational manner that is supported by learning events that help the person to hold that interest. Sustained interest increases engagement and motivation to learn, as well as facilitates strategy use and deeper processing. Thus, the development of sustained personal interest is an important component of learning.

Several researchers have investigated the development of interest in more detail. Ainley, Hidi, and Berndorff (2002) reported that situational factors lead to the development of sustained personal interest and that personal interest was related to positive affect, persistence, and learning. Durik and Harackiewicz (2007) described similar findings with one important exception. Experimental manipulations designed to catch learners' attention were effective if the learner has initial interest but undermined learning if the learner had little initial interest. Chen and Darst (2002) reported that background level of expertise had a mediating effect on situational and personal interest. These results suggested that both situational and personal interest are important but that manipulations designed to increase situational interest may not lead to sustained personal interest or learning. These findings also mirrored research on seductive details (i.e., text segments that are interesting but unimportant to a text's main themes), which found that seductive information may reduce learning (Harp & Mayer, 1998; Lehman, Schraw, McCrudden, & Hartley, 2007).

DEVELOPING SUSTAINED INTEREST

Mitchell (1993) originally proposed a simple three-stage model in which situational interest leads to personal interest, which leads to higher learning. Hidi and Renninger (2006) proposed a more sophisticated model in which interest develops through four continuous stages, including triggered situational interest, maintained situational interest, emerging personal interest, and well-developed individual interest. Triggered situational interest refers to

a change in interest that is related directly to a temporary change in the stimuli, environment, or to-be-learned information. These changes may be evoked by a wide variety of factors, including highly relevant information, surprising or unexpected information, information that is incongruous with the task, a change in environment, or the enthusiasm of a teacher or mentor. Maintained situational interest refers to a state of focused attention and greater personal investment with the to-be-learned information. These changes usually are supported externally by a stimulating text, task, or teacher. In addition, maintained interest is sustained through meaningful tasks and personal involvement. Emerging individual interest refers to a state in which interest does not need to be sustained externally and one in which the interest becomes an enduring disposition. These changes are supported by increased curiosity, greater domain knowledge, and a perceived sense of pleasure and usefulness in the activity. Well-developed individual interest refers to an enduring change in disposition for the information or activity. These changes are characterized by positive affect, greater intrinsic motivation, extensive knowledge about the domain, a high level of procedural expertise, and an ability to monitor and self-regulate one's future development in the domain.

The four-phase model of interest development provides a concise explanation of how interest develops, is sustained, and how it impacts engagement and learning. A number of studies provide empirical support for the model (Ainley et al., 2002; Durik & Harackiewicz, 2007). Nevertheless, a number of important issues remain as of 2008 for future research. One is whether the model is equally applicable across the lifespan. It may be the case that interest develops in a somewhat different way, or on a different developmental trajectory, for children compared to older students or adults. A second issue is whether interest is a necessary precursor of expertise or independent of expertise. For example, someone may develop considerable knowledge of investment strategies out of financial necessity rather than personal interest. A third is whether interest development is subject to reversals and, if so, how interest erodes and is replaced by new interests. A fourth issue pertains to how environmental factors affect the transition of early interest to sustained personal affect. As some research indicates, well meaning attempts to increase interest may actually have a negative effect on affect and learning (Lehman et al., 2007; Schraw & Lehman, 2001).

EFFECTS ON STUDENT LEARNING

Definitive evidence indicates that situational and personal interests are related to learning in three important ways. One way is that interest increases motivation, engagement, and persistence. Situational interest has a

positive effect on extrinsic motivation, whereas personal interest has a positive long-term effect on intrinsic motivation. Presumably, external factors such as teachers and interesting textbooks provide external motivation to learn more about a domain. Once situational interest develops into well-developed individual interest, external factors likely play a smaller role in motivation, whereas intrinsic motivation and enjoyment play larger roles.

Extrinsic and intrinsic motivation are essential precursors to engagement. Students who are interested in a topic or activity are more likely to engage and persist, which in turn leads to the acquisition of new skills and knowledge. Motivation helps individuals to develop the confidence to undertake a new learning activity or to venture into an unfamiliar intellectual domain such as mathematics and science. For example, Renninger (2000) reported a compensatory effect in which high interest compensated for lower achievement and lower ability. Engagement enables learners to develop conceptual knowledge and essential procedural skills within a domain. In turn, motivation and engagement facilitate persistence within a domain that is necessary to develop true expertise. Persistence produces greater competence, which increases confidence and self-efficacy, and makes it easier and more enjoyable to learn.

A second way that interest is related to learning is through strategy use (Alexander & Jetton, 1996; Schraw & Lehman, 2001). Students who are interested in a topic report using more strategies are more likely to monitor their performance and shift strategies when necessary and are better able to self-regulate their learning. Increased strategy use, metacognitive monitoring, and self-regulation improve the efficiency of skill and knowledge acquisition as well as the amount of information learned.

A third way that interest affects learning is through deeper information processing. Schiefele (1999) found that high-interest learners were more likely to construct deeper mental representations of a text. This correlation may be due in part to the fact that high-interest learners are more likely to possess topic-specific knowledge and learning strategies. Yet regardless of knowledge and strategies, students with high levels of interest are more likely to engage in an activity, persist, report positive affect, and focus more of their effort on constructing a deeper understanding of the skill or domain that they are studying.

SUGGESTIONS FOR INCREASING INTEREST

Research suggests that interest is an important precursor to learning and is changeable. A number of suggestions are included below that are based on previous articles (Schraw, Flowerday & Lehman, 2001; Hidi & Renninger, 2006). Each of these strategies may have a unique facilitative effect;

thus, it is reasonable to use as many strategies as are feasible in the classroom.

1. **Model interest and engagement in the classroom.**
Some teachers are enthusiastic about what they teach and demonstrate that enthusiasm on a day-to-day basis. Teacher enthusiasm develops initial interest due to events, topics, and observation. One way to promote and sustain interest is for teachers, tutors, or peers to model it.
2. **Offer meaningful choices to students.** Choice is hypothesized to promote a greater sense of self-determination because it satisfies students' need for autonomy. Empirical studies of choice support this view. Teachers also suggest that choice increases students' interest in a text.

Teachers interviewed by Flowerday and Schraw (2000) recommended offering a wide variety of choices to all students on a regular basis. In terms of when to use choice, teachers suggested offering meaningful choices to students of all ages, especially those who demonstrate low interest otherwise. Regarding where to offer choice, teachers do so in a variety of settings, including tasks such as homework and student assessment, as well as academic and social activities. Regarding how to use choice, teachers offered the following suggestions: offer simple choices at first, help students practice making good choices, provide feedback about the choices students make, use team choices for younger or less-experienced students, and provide information that clarifies the choice. For example, one teacher stated that she lets her students choose from a menu of five or six stories that she knows are interesting and suitable to her students.

Use engaging real-life problems. Students are engaged by interesting topics, but also by challenging and interesting activities. Several studies suggest that real-life problems are of interest to students and that even boring activities can be made more interesting if students challenge themselves. Hidi and Renninger (2006) recommended activities that require multiple students, including cooperative learning groups, team projects, one-on-one tutors, and interactive problem solving with or without teachers.

Use well organized texts and learning materials. Well organized texts are those that are coherent and informationally complete. These two variables are strongly related to interest and learning in text (Schraw, 1997). As texts become less user friendly or as students become less knowledgeable about text content, it is recommended that teachers make a greater effort to provide useful background knowledge about the text, given that knowledge and coherence appear to make separate contributions.

Select texts and learning materials that are vivid. Texts are vivid because they contain rich imagery, suspense, provocative information that surprises the reader, and engaging themes. Research suggests that text vividness has a positive impact on interest and learning provided the vivid information is germane to the learning task. Texts that include irrelevant or highly seductive information may actually interfere with learning by diverting readers' attention from important text segments (Harp & Mayer, 1998; Lehman et al., 2007).

Use texts that students know about. Prior knowledge is related positively to interest and deeper learning. Teachers should follow one of two strategies to promote interest. One is to use texts whose content is familiar, though not highly familiar, to the majority of students. Familiarity with text helps students generate thematic inferences within the text as well as between the text and prior knowledge. A second strategy is to provide pre-reading background information to help students better comprehend what they are asked to learn. This can be done directly by the teacher or via small group discussions among students.

Encourage students to be active learners. Students who actively make meaning learn more information at a deeper level. A number of researchers have suggested that interest increases active learning as well as the reverse (Mitchell, 1993; Hidi & Renninger, 2006). One way that students become more active is by using specific learning strategies such as predicting and summarizing. Another way is by using general study strategies in which students identify what they already know, want to know, and have learned.

Provide relevance cues for students. Relevance refers to whether information is salient to a task (McCrudden & Schraw, 2007). Almost any kind of information can become relevant to a learning situation. Understanding what is relevant to the learning task beforehand increases interest and learning. Teachers should highlight relevant themes and information for students before they begin to read or study. This is especially important for low-interest students. Several strategies may be used for highlighting the relevance of information: (a) encouraging students to set personal reading goals before reading, (b) helping students understand what is most important or salient to the reading task, (c) asking students to focus on cause and effect relationships, and (d) asking students to explain the text to other students.

Highlighting the relevance of information or goals for learning may increase the perceived value of information. Previous research suggests that individuals are more motivated to process information they value. Although valuing may be due in part to personal interest, it also appears to be

affected by the culture of the school as well as teacher values. Teachers who highlight the relevance and value of information and skills for students may also increase interest.

Do not use seductive information gratuitously. Research suggests that information that is irrelevant, out of place, or increases the relative cognitive load of information processing may actually interfere with learning. For example, Harp and Mayer (1998) found that highly interesting segments that were added to a text passage, but were not important or relevant, decreased learning of main idea, even though memory for the seductive information was quite high. One recommended rule is to incorporate a limited amount of highly interesting information, but make sure it is relevant to the learning task and does not seem incongruous with other to-be-learned information (Lehman et al., 2007).

INTRINSIC AND EXTRINSIC MOTIVATION

Teachers can often readily identify students who demonstrate high or low motivation in a certain task. Motivated students engage in the task with intensity and feeling, whereas unmotivated students procrastinate and indicate in other ways that they would rather do something else. These differences exemplify the *quantitative* dimension of motivation, ranging from high to low. Teachers can often also identify highly motivated students who engage in tasks in different ways. Some may attempt to finish the task quickly, while others may seek more information. Some may persist, while others may begin enthusiastically but give-up when they encounter difficulty. These differences reflect the *qualitative* dimension of motivation. The distinction between intrinsic and extrinsic motivation has been one of the important theoretical conceptualizations of qualitative differences in engagement.

Intrinsic motivation refers to engagement in an activity with no reason other than the enjoyment and satisfaction of engagement itself. By comparison, extrinsic motivation refers to engagement that provides means to ends that go beyond the engagement itself. The goals of extrinsically motivated engagement might be the attainment of tangible rewards such as money, prizes, or other benefits; intangible rewards such as social approval, a sense of worthiness, or even a sense of conscientiousness; or the avoidance of tangible and intangible punishments such as time-out, scolding, rejection or sense of low self-worth.

THE ORGANISMIC SOURCES OF EXTRINSIC AND INTRINSIC MOTIVATION

Motivational theorists of the early 20th century searched for general principles of behavior. Theories of the period focused primarily on the motivations triggered by organismic physiological drives or needs such as food, sleep, procreation, and security (e.g., Hull, 1943). Organisms

were perceived to be motivated to behave in ways that replenish biological deficits and secure survival. Because behavior that aims to satisfy a physiological deficit is done in order to achieve a goal and not for its own sake, it represents a type of extrinsic motivation.

Taking a different approach to motivation, behaviorist psychologists (e.g., Skinner, 1953) argued that behavior can be explained by the organisms' motivation to approach pleasant and desirable outcomes and to avoid unpleasant and undesirable outcomes. Pleasant outcomes constitute a reward, and enhance the chance that a behavior will recur, whereas unpleasant outcomes constitute a punishment and reduce the chance that a behavior will recur. Behaviorist psychologists argued that human (and animal) behavior can be explained by the various rewards and punishments in the environment. Thus, from a behaviorist perspective, all motivation is extrinsic.

However, during the middle of the 20th century, several theorists challenged the mechanistic models of the drive and behaviorist perspectives. These theorists relied on observations indicating that sometimes people (and animals) engage in behavior without an apparent reward. This engagement was seen to manifest universally early in life in children's exploration and play (Berlyne, 1960; White, 1959). But it also appears among older people who engage in games and hobbies. These observations seemed to suggest that such engagement is inherently enjoyable and satisfying. This type of motivation was contrasted with behavior propelled by "extrinsic" forces, and was labeled "intrinsic" motivation (Hunt, 1965).

Researchers of the period proposed a variety of theoretical explanations for intrinsic motivation, including characteristics of activities such as novelty and fantasy and biological mechanisms such as play instincts, curiosity, and need for stimulation. In a seminal paper, White (1959) reviewed several of these theoretical explanations and argued for their integration in a motive that developed along evolution, which he termed "effectance" motivation, or need for competence. White argued that this motive propels children to explore their surroundings, manipulate objects, and interact with others in ways that promote mastery of the environment. Unlike physiological needs, which operate on a homeostatic principle—that is, they are aroused when the organism is deficient in a resource, and operate to guide action towards reducing the deficiency—effectance motivation is aroused particularly when no deficiency exists. Engagement out of effectance motivation does not have a clear end-goal; rather, it is the engagement in the activity itself that elicits positive feelings of efficacy, which constitute an "intrinsic" reward.

Taking a different ideological approach, humanistic psychologists of the mid 20th century such as Maslow (1954) and Rogers (1963) challenged the drive and

behaviorist perspectives by suggesting the existence of human needs that give rise to intrinsic motivation. Maslow, for example, argued that the physiological and safety needs, which he labeled "deficiency needs," are distinct from self-actualization needs, such as the need to develop talents, achieve comprehension, and fulfill potential, which he labeled "growth" needs. While the former provide the basis for extrinsic types of motivation, the latter provide the basis for intrinsic types of motivation.

At the beginning of the 21st century, many theorists still hold that intrinsic and extrinsic motivations are based in organismic needs. One such comprehensive theoretical framework—self-determination theory (SDT) (Deci & Ryan, 1985; Ryan & Deci, 2000)—explicitly asserts that humans are motivated by three basic psychological needs: for competence, relatedness, and autonomy. The need for competence in SDT is what White (1959) called effectance motivation. The need for relatedness refers to people's need to belong and to feel accepted by others. The need for autonomy refers to people's need to feel self-determined to be the source of their own action (deCharms, 1968). Like physiological needs, these psychological needs are thought to represent necessary nourishment for psychological development and growth. When an individual's three needs are fully satisfied, engagement in action is intrinsically motivated and promotes adaptive development and well-being. When one of the needs is unsatisfied, engagement is likely to be extrinsically motivated and development may be hindered.

MODELS OF INTRINSIC AND EXTRINSIC MOTIVATION

Whereas organismic needs energize intrinsic and extrinsic motivations, the concept of need in itself is too general to explain engagement in specific behaviors and too vague to be a guide for empirical research (Harter, 1981; Pintrich & Schunk, 2002). Therefore, during the second half of the 20th century, researchers developed models that described how motivation triggered by needs manifests in intrinsic and extrinsic motivation in specific domains and activities. These models also explained how factors in the environment may shape and affect the type of motivation that people manifest in different domains.

In one important model of intrinsic motivation, Csikszentmihalyi (1990) focused on a phenomenological state of full absorption in an activity, which he labeled "flow." In this pure form of intrinsic motivation, "Concentration is so intense that there is no attention left over to think about anything irrelevant, or to worry about problems. Self-consciousness disappears, and the sense of time becomes distorted" (p. 71). Csikszentmihalyi interviewed professional artists, athletes, rock climbers, and chess players about their flow experiences and concluded

that flow is most likely to be experienced when there are clear goals to be achieved and there is an optimal balance between the challenge posed by the activity and the person's level of skill. In addition, flow is experienced when there is immediate feedback on one's action and when the person feels a sense of control over the environment. According to Csikszentmihalyi, flow experiences promote further intrinsic motivation as well as skills in a domain. Since experiences of flow are rewarding, people are motivated to replicate the experience. Through engagement in challenging activities, skills develop and the person is motivated to seek more difficult challenges in the domain. Thus, growth of competencies and intrinsic motivation in the domain facilitate each other.

In a different program of research, Harter (1981, 1992) developed a model detailing how intrinsic motivation in different domains is shaped by experiences of success and failure as well as reinforcement from significant others. According to Harter, effectance motivation leads children to seek challenges, learn out of curiosity and for the experience of pleasure, and rely on themselves for a sense of success. When curiosity, independence, and exploration result with experiences of mastery and meet the approval and encouragement of parents or teachers, children experience pleasure, feel competent and in control of their environment, and have stronger intrinsic motivation for the domain or activity. However, when such engagement results with experiences of failure and meet disapproval by others, children feel anxious, perceive themselves to have low competence and control, and have lower intrinsic motivation. According to Harter, when parents and teachers demand compliance and employ extrinsic rewards and punishments, children develop extrinsic motivation for activities and domains.

In yet another elaborate model, self-determination theorists (Deci & Ryan, 1985; Ryan & Deci, 2000) suggested that intrinsic and extrinsic motivation can be arranged on an internal-external continuum according to the individual's perception of relative autonomy. Motivations that involve a higher perception of autonomy are more internal and represent a higher quality of engagement. Intrinsic motivation is positioned on the internal end of the continuum, and represents a perception of full autonomy in engagement. "External regulation" lies on the external end of the continuum and describes the sense of coercion and external control that individuals experience when they engage in an undesirable task in order to avoid punishment or achieve rewards. Between these poles are three other types of extrinsic motivation that vary in level of perceived relative autonomy. Whereas most activities may not be intrinsically motivating, SDT proposes that people have an organismic tendency to internalize motivation for uninteresting and enjoyable activities. However, internalization is likely to occur only if the

three psychological needs for competence, relatedness, and autonomy are satisfied.

ASSESSING INTRINSIC AND EXTRINSIC MOTIVATION

Researchers have used multiple methods to assess intrinsic and extrinsic motivation, either as a motivational "state" the motivation a person has in a particular task or as a motivational "trait" the type of motivation a person has a tendency to display across domains and activities (Harter & Jackson, 1992). One common indicator of "state" intrinsic motivation is "free choice" the amount of time spent on a task when alternative activities are available and no reward is offered (e.g., Deci, 1971; Lepper, Greene, & Nisbett, 1973). While an important measure in the literature, "free choice" is also somewhat problematic because there may be reasons other than intrinsic motivation for choosing a certain activity over others (e.g., wanting to prove worthiness) (Ryan, Koestner & Deci, 1991).

Perhaps the most frequently used method of assessing intrinsic and extrinsic motivation has been through participants' self-report. Early in her research, Harter (Harter & Zigler, 1974) assessed "trait" intrinsic motivation with an instrument comprised of four tasks, each targeting a different component of effectance motivation: seeking variation, preference for novelty, engagement for mastery, and preference for challenge. In each task, the child had a choice between two options indicating high or low level of effectance motivation. A few years later, Harter (1981) developed a different self-report instrument that was comprised of five scales of items, each assessing a different motivational component. Each item in the instrument *contrasted* intrinsic and extrinsic motivation (e.g., preference for challenging versus easy work). But several researchers, including Harter (1992) herself, recognized the possibility of adopting intrinsic and extrinsic motivation simultaneously a possibility masked by instruments asking participants to choose *either* intrinsic *or* extrinsic motivation. Therefore, researchers divided Harter's instrument into separate intrinsic and extrinsic scales (Harter & Jackson, 1992; Lepper et al., 2005). Similar self-report scales have also been constructed by other motivational researchers (e.g., Pintrich et al., 1993; Ryan & Connell, 1989).

INTRINSIC MOTIVATION, EXTRINSIC REWARDS, AND OUTCOMES

The research literature is quite unanimous with regard to the benefits of intrinsic motivation to learning and development (Stipek, 1996). Engagement out of intrinsic motivation requires no external incentives and enhances motivation to engage again in the future. Studies also suggest that engagement out of intrinsic motivation is associated with enhanced

comprehension, creativity, cognitive flexibility, achievement, and long-term well-being. By comparison, engagement out of extrinsic motivation may cease once the external motivator is removed. Moreover, extrinsic motivation is often associated with negative indicators of achievement and well-being. It is clear, however, that extrinsic motivation is preferable to having no motivation at all. Some perspectives also emphasize the possible motivational benefits of having both intrinsic and extrinsic motivation for an activity (Lepper & Henderlong, 2000). Unfortunately, research findings point quite consistently to a gradual decline in students' academic intrinsic motivation, and sometimes also extrinsic motivation, over years of schooling (Harter, 1981; Sansone & Morgan, 1992; Lepper et al., 2005). These trends have been attributed to the prevalence of extrinsic forces in schools such as tests and token economies, to the irrelevance of school tasks to students' lives and, more generally, to the growing mismatch between characteristics of school environments and the needs of adolescence for autonomy, self-expression, and meaningful social interaction (Eccles et al., 1993; Lepper & Henderlong, 2000).

The use of extrinsic rewards as a motivational strategy has spurred a persistent and heated debate in the literature (Sansone & Harackiewicz, 2000). Generally, humanistic motivation researchers argue that offering extrinsic rewards has detrimental effects on existing intrinsic motivation and is morally problematic (Kohn, 1993). Behaviorist researchers argue that offering extrinsic rewards has either negligible effects on intrinsic motivation or that it actually contributes to intrinsic motivation (Eisenberger & Cameron, 1996). What emerges from the research is that extrinsic rewards have no universal effect. Rather, the effect depends on the meaning of the reward to the child. Research also points to varying effects of different types of rewards and of different standards for their administration. For example, rewards that are expected, contingent on engagement or on task completion, and tangible are more likely to be detrimental to intrinsic motivation than rewards that are unexpected, not contingent, and intangible (e.g., verbal, social approval) (Lepper & Henderlong, 2000). More specifically, when positive rewards are perceived to provide valid information on student's competence—for example, performance-contingent rewards or feedback—they are likely to enhance intrinsic motivation. In contrast, when rewards are perceived as controlling and as suppressing the student's autonomy, they are likely to interfere with intrinsic motivation.

IMPLICATIONS FOR EDUCATORS

While some important variation exists (e.g., Nisan, 1992), there seems to be a wide-spread consensus among researchers and educators that enhancing intrinsic motivation among students is beneficial. Students' intrinsic motivation

is enhanced when practices promote their sense of personal autonomy, when schoolwork is challenging and relevant to students, when social relationships are supportive, and when environments are physically and psychologically safe. Practices that promote these environmental characteristics include providing students with choices among activities and between ways of completing tasks, encouraging students to explore and pursue their interests, building on their backgrounds and prior experiences in constructing tasks, encouraging them to collaborate, incorporating fantasy in activities, providing feedback that is informative and frequent, and reducing rewards that are controlling (Lepper & Henderlong, 2000; Pintrich & Schunk, 2002).

Nevertheless, sometimes students are required to engage in tasks that they are not motivated to do. Thus, extrinsic motivation cannot be, and should not be, abandoned (Hidi & Harackiewicz, 2000). However, educators should pursue the internalization of students' extrinsic motivation for these tasks. Such internalization can be promoted by employing as many of the recommendations specified above as possible and, in addition, educators should make the value of the activity explicit and clear. This can be done most effectively through modeling and through providing a clear and age-appropriate rationale for the requirement (Assor et al., 2002).

ITEM ANALYSIS

Item analysis is a general term that refers to the specific methods used in education to evaluate test items, typically for the purpose of test construction and revision. Regarded as one of the most important aspects of test construction and increasingly receiving attention, it is an approach incorporated into item response theory (IRT), which serves as an alternative to classical measurement theory (CMT) or classical test theory (CTT). Classical measurement theory considers a score to be the direct result of a person's true score plus error. It is this error that is of interest as previous measurement theories have been unable to specify its source. However, item response theory uses item analysis to differentiate between types of error in order to gain a clearer understanding of any existing deficiencies. Particular attention is given to individual test items, item characteristics, probability of answering items correctly, overall ability of the test taker, and degrees or levels of knowledge being assessed.

THE PURPOSE OF ITEM ANALYSIS

There must be a match between what is taught and what is assessed. However, there must also be an effort to test for more complex levels of understanding, with care taken to avoid over-sampling items that assess only basic levels of knowledge. Tests that are too difficult (and have an insufficient floor) tend to lead to frustration and lead to deflated scores, whereas tests that are too easy (and have an insufficient ceiling) facilitate a decline in motivation and lead to inflated scores. Tests can be improved by maintaining and developing a pool of valid items from

which future tests can be drawn and that cover a reasonable span of difficulty levels.

Item analysis helps improve test items and identify unfair or biased items. Results should be used to refine test item wording. In addition, closer examination of items will also reveal which questions were most difficult, perhaps indicating a concept that needs to be taught more thoroughly. If a particular distracter (that is, an incorrect answer choice) is the most often chosen answer, and especially if that distracter positively correlates with a high total score, the item must be examined more closely for correctness. This situation also provides an opportunity to identify and examine common misconceptions among students about a particular concept.

In general, once test items have been created, the value of these items can be systematically assessed using several methods representative of item analysis: a) a test item's level of difficulty, b) an item's capacity to discriminate, and c) the item characteristic curve. Difficulty is assessed by examining the number of persons correctly endorsing the answer. Discrimination can be examined by comparing the number of persons getting a particular item correct with the total test score. Finally, the item characteristic curve can be used to plot the likelihood of answering correctly with the level of success on the test.

ITEM DIFFICULTY

In test construction, item difficulty is determined by the number of people who answer a particular test item correctly. For example, if the first question on a test was answered correctly by 76% of the class, then the difficulty level (*p* or percentage passing) for that question is *p* = .76. If the second question on a test was answered correctly by only 48% of the class, then the difficulty level for that question is *p* = .48. The higher the percentage of people who answer correctly, the easier the item, so that a difficulty level of .48 indicates that question two was more difficult than question one, which had a difficulty level of .76.

Many educators find themselves wondering how difficult a good test item should be. Several things must be taken into consideration in order to determine appropriate

difficulty level. The first task of any test maker should be to determine the probability of answering an item correctly by chance alone, also referred to as guessing or luck. For example, a true-false item, because it has only two choices, could be answered correctly by chance half of the time. Therefore, a true-false item with a demonstrated difficulty level of only *p* = .50 would not be a good test item because that level of success could be achieved through guessing alone and would not be an actual indication of knowledge or ability level. Similarly, a multiple-choice item with five alternatives could be answered correctly by chance 20% of the time. Therefore, an item difficulty greater than .20 would be necessary in order to discriminate between respondents' ability to guess correctly and respondents' level of knowledge. Desirable difficulty levels usually can be estimated as halfway between 100 percent and the percentage of success expected by guessing. So, the desirable difficulty level for a true-false item, for example, should be around *p* = .75, which is halfway between 100% and 50% correct.

In most instances, it is desirable for a test to contain items of various difficulty levels in order to distinguish between students who are not prepared at all, students who are fairly prepared, and students who are well prepared. In other words, educators do not want the same level of success for those students who did not study as for those who studied a fair amount, or for those who studied a fair amount and those who studied exceptionally hard. Therefore, it is necessary for a test to be composed of items of varying levels of difficulty. As a general rule for norm-referenced tests, items in the difficulty range of .30 to .70 yield important differences between individuals' level of knowledge, ability, and preparedness. There are a few exceptions to this, however, with regard to the purpose of the test and the characteristics of the test takers. For instance, if the test is to help determine entrance into graduate school, the items should be more difficult to be able to make finer distinctions between test takers. For a criterion-referenced test, most of the item difficulties should be clustered around the criterion cut-off score or higher. For example, if a passing score is 70%, the vast majority of items should have percentage passing values of

Extreme group method			
Item number	Correct response proportion in the top percentile	Correct response proportion in the bottom percentile	Discriminability index
1	.92	.40	.52
2	.97	.93	.04
3	.61	.74	-.13

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

$p = .60$ or higher, with a number of items in the $p > .90$ range to enhance motivation and test for mastery of certain essential concepts.

DISCRIMINATION INDEX

According to Wilson (2005), item difficulty is the most essential component of item analysis. However, it is not the only way to evaluate test items. Discrimination goes beyond determining the proportion of people who answer correctly and looks more specifically at who answers correctly. In other words, item discrimination determines whether those who did well on the entire test did well on a particular item. An item should in fact be able to discriminate between upper and lower scoring groups. Membership in these groups is usually determined based on their total test score, and it is expected that those scoring higher on the overall test will also be more likely to endorse the correct response on a particular item. Sometimes an item will discriminate negatively, that is, a larger proportion of the lower group select the correct response, as compared to those in the higher scoring group. Such an item should be revised or discarded.

One way to determine an item's power to discriminate is to compare those who have done very well with those who have done very poorly, known as the extreme group method. First, identify the students who scored in the top one-third as well as those in the bottom one-third of the class. Next, calculate the proportion of each group that answered a particular test item correctly (i.e., percentage passing for the high and low groups on each item). Finally, subtract the p of the bottom performing group from the p for the top performing group to yield an item discrimination index (D). Item discriminations of $D = .50$ or higher are considered excellent. $D = 0$ means the item has no discrimination ability, while $D = 1.00$ means the item has perfect discrimination ability.

In Figure 1, it can be seen that Item 1 discriminates well with those in the top performing group obtaining the correct response far more often ($p = .92$) than those in the

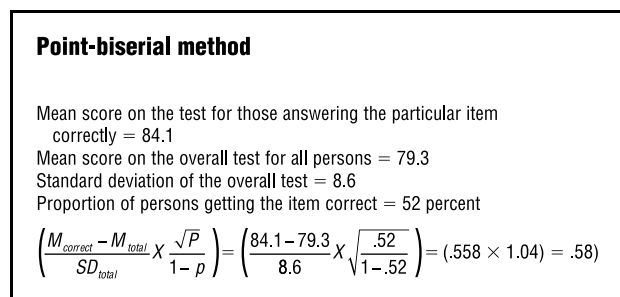

Figure 2 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

low performing group ($p = .40$), thus resulting in an index of $.52$ (i.e., $.92 - .40 = .52$). Next, Item 2 is not difficult enough with a discriminability index of only $.04$, meaning this particular item was not useful in discriminating between the high and low scoring individuals. Finally, Item 3 is in need of revision or discarding as it discriminates negatively, meaning low performing group members actually obtained the correct keyed answer more often than high performing group members.

Another way to determine the discriminability of an item is to determine the correlation coefficient between performance on an item and performance on a test, or the tendency of students selecting the correct answer to have high overall scores. This coefficient is reported as the item discrimination coefficient, or the point-biserial correlation between item score (usually scored right or wrong) and total test score. This coefficient should be positive, indicating that students answering correctly tend to have higher overall scores or that students answering incorrectly tend to have lower overall scores. Also, the higher the magnitude, the better the item discriminates. The point-biserial correlation can be computed with procedures outlined in Figure 2.

In Figure 2, the point-biserial correlation between item score and total score is evaluated similarly to the extreme group discrimination index. If the resulting value is negative or low, the item should be revised or discarded. The closer the value is to 1.0, the stronger the item's discrimination power; the closer the value is to 0,

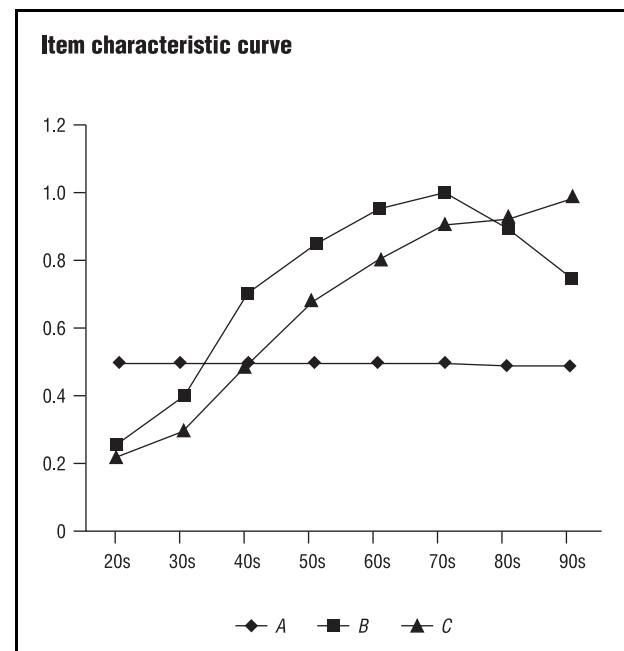

Figure 3 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

the weaker the power. Items that are very easy and answered correctly by the majority of respondents will have poor point-biserial correlations.

CHARACTERISTIC CURVE

A third parameter used to conduct item analysis is known as the item characteristic curve (ICC). This is a graphical or pictorial depiction of the characteristics of a particular item, or taken collectively, can be representative of the entire test. In the item characteristic curve the total test score is represented on the horizontal axis and the proportion of test takers passing the item within that range of test scores is scaled along the vertical axis.

For Figure 3, three separate item characteristic curves are shown. Line A is considered a flat curve and indicates that test takers at all score levels were equally likely to get the item correct. This item was therefore not a useful discriminating item. Line B demonstrates a troublesome item as it gradually rises and then drops for those scoring highest on the overall test. Though this is unusual, it can sometimes result from those who studied most having ruled out the answer that was keyed as correct. Finally, Line C shows the item characteristic curve for a good test item. The gradual and consistent positive slope shows that the proportion of people passing the item gradually increases as test scores increase. Though it is not depicted here, if an ICC was seen in the shape of a backward S, negative item discrimination would be evident, meaning that those who scored lowest were most likely to endorse a correct response on the item.

ITEM RESPONSE THEORY

Item response theory (IRT) is an approach to modern educational and psychological measurement that posits a particular notion about cognition and sets forth sophisticated statistics to appraise cognitive processes. Its objective is to reliably calibrate individuals and test stimuli (i.e., items and exercises) on a common scale that is interpreted to show the individuals' ability or proficiency and specified characteristics of the test stimuli.

IRT is attractive for a number of reasons but principally because it is presumed that IRT-based estimates of examinees' ability are more precise than can be garnered through traditional means, such as summing the number of correct responses to a set of test items or exercises. Also, IRT is applicable to many practical testing problems, such as generalizability of test results, various item analyses, examining test bias and differential item functioning, equating test forms, estimating construct parameters, domain scoring, and adaptive testing.

In the IRT theory, cognitive processes are hypothesized as abilities or proficiencies. Some examples are reading, computing, and reasoning problems through to credible solutions, as well as beliefs, attitudes, opinions, and likely desires and aspirations, too. In short, almost anything that is a cognitive process. Some skills or talents, like playing a musical instrument, giving a theatrical performance and some physical acts such as running or successfully hitting a baseball, can be accommodated in the theory as well. Each ability or proficiency is conceived as lying along a continuum that ranges from none at all to complete mastery. In statistical terms, the range is infinite ($\pm\infty$). Figure 1 depicts this notion graphically.

Graphical depiction of ability or proficiency continuum

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

As cognitive processes, abilities and proficiencies are deeply seated in the brain and cannot be directly observed. For this reason, they are described as latent, and often as latent traits. Some persons working with IRT believe that describing aspects of cognition as traits is too limiting; It does not capture the fact of their malleability or the notion that they may be influenced by environmental and social factors; hence, more generic terms such as abilities and proficiencies are sometimes used. In this essay, the term ability is used.

The notion of mental abilities ranging along a continuum contrasts with classical testing theory (CTT) in which knowledge is conceived as being circumscribed within a domain

(e.g., a reading domain), and a true score for any particular examinee can be estimated for that knowledge domain. In CTT, the more precisely the true score is estimated, the less error in measurement, and hence the greater reliability

A principal objective of IRT is to determine the point along the ability continuum that best calibrates a particular individual to the scale. This point—the test score expressed in IRT terms—is interpreted to reflect the individual's ability on whatever is the object of measurement (e.g., reading). Figure 2 illustrates this foundational IRT notion. For mathematical reason, ability is expressed as theta (θ) and when referring to individuals, the continuum is called the θ scale.

Graphical depiction of individuals along ability or proficiency continuum

Figure 2 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

As seen in Figure 2, a given person may be low in the ability (shown as toward the left side of the θ scale), whereas another may be in the middle, while a third person may be high (shown as toward the right side of the θ scale). There is no assumption about the spread of individuals as in a bell-shaped (normal) distribution: all persons in a population could be high in the ability or all could be in the middle or have any other dispersion.

Of course, determining where a given individual's θ is situated along the scale (i.e., his or her ability) requires that some questions (test stimuli: items or exercises) be administered to the individual so that the θ estimate may be calculated. For the calculation, it is necessary to know characteristics of these test stimuli, a feature of IRT called *item characteristics*. Three commonly-used item characteristics are 1) its level of difficulty along the continuum, 2) its discrimination in detecting differences in ability between examinees (an item that everyone responds to correctly yields no discrimination), and 3) the likelihood of low ability examinees guessing a correct answer. Figure 3 depicts the notion of test characteristics being placed along the continuum.

Graphical depiction of many individuals dispersed along ability continuum

Figure 3 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

Just as examinees may be located at any particular point along the continuum, so too may characteristics of items be situated at any point for their characteristic. In other words, any given items may be low in difficulty or have low discriminating power or be relatively simple to guess whereas another item may be middle or high in characteristics. Many items are typically situated all along the scale, reflecting wide dispersion.

To repeat, the three ingredients of IRT are: the scale, the examinees, and the items. As earlier stated, the scale's range is infinite, ($\pm\infty$). What remains is to determine the θ value for each examinee in the tested sample and the characteristics of the employed test items. Characteristics for the items can be discussed next.

In IRT (as well as in some other statistical contexts), item characteristics are plotted on a curve, called an ICC (item characteristics curve). While any number of characteristics may be plotted, it is common to display three of them: the discrimination, the difficulty, and the guessing. By convention, these are labeled as a , b , and c . In a statistical sense, the known characteristics of any given item are representative of a population of like items and hence are labeled *parameters*. The a , b , and c characteristics are thus labeled as a parameter or b parameter or c parameter. When all three characteristics are estimated, the IRT model is called the three-parameter model (3PL).

In IRT, there are many variations of ICCs. For instance, a common circumstance in IRT work is to estimate only a single item parameter, its difficulty (b parameter). This is the 1PL, and usually falls into an IRT category of estimation called the Rasch model, an eponym for the Danish mathematician Georg Rasch. The 3PL accounts for the most common IRT applications. Item characteristics for the 3PL are plotted in Figure 4.

ICC of one item, displaying three characteristics

Figure 4 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

In Figure 4, there are two scales, represented on the vertical X (abscissa) and horizontal Y (ordinate) axis. The X axis is the probability of θ , labeled $P(\theta)$ meaning the probability of a given θ value. It ranges from 0 to 1.0 and is considered the likelihood of getting the item correct (for dichotomous items). The Y axis is the IRT θ scale which (theoretically at least) ranges ($\pm\infty$). For interpretability, however, the X scale is expressed in standardized units with a mean of 0 and standard deviation 1; since nearly all of the population is contained within the ± 3 standard deviations, this is all of the range of the scale that is typically shown.

Regarding the ICC itself, the reader can see that the curve is shaped like a lazy S for an item with meritorious characteristics (but obviously it can assume almost any shape). Technically, the curve is an ogive, but many authors simply refer to it as the ICC. It begins at the lower left, which indicates the c parameter (guessing by low ability examinees: here almost -3 standard deviations from the mean 0). In the figure, this starting point is about .10, meaning that persons of very low ability still have about a ten percent probability of getting the item correct, even by mere guessing. As the curve progresses to the right, reflecting more and more ability, the curve slopes upward, indicating that as ability increases so does the probability of a correct response. The slope of the ICC represents the a parameter, the item's discriminating power. Next, the reader can observe that the overall location of the curve along the θ scale and imagine a vertical line drawn from its mid-point down to the Y axis. In this example, that line would intersect the Y axis at about .5, meaning that this item is best suited to examinees who are slightly more able than average examinees (about a half standard deviation above the mean ability). It is important to realize from this example that an ICC can be situated anywhere along the θ scale, and its mid-point reflects its difficulty, the b parameter. In Figure 4, then, all three item characteristics can be seen: (a) the discrimination, (b) the difficulty, and (c) the guessing parameters.

When a person is learning IRT it is important to appreciate the fact that persons and items are calibrated on the same scale. This allows observers to learn features of each ingredient in IRT (persons and items) from the other. In other words, when test makers know the characteristics of items, they can observe (through the test) which ones a particular examinee gets right and wrong and thereby determine his or her ability. Conversely, when test makers know the θ values for a relatively large number of examinees, they can calibrate items to the scale. This reciprocal finding is something akin to saying that if a teacher knows a student's grade point average the teacher can ipso facto identify something about the stu-

dent's study habits and vice versa (not a perfect indicator but in the main a reliable one).

To persons new to IRT or not experienced in statistics, it may seem perplexing to state that items are calibrated to the scale from what test makers know about examinees' abilities and examinees are fitted to the scale from what test makers know about items. It seems a bit like the question: "Which came first, the chicken or the egg?" This is a relevant observation in IRT. Mathematically, this issue is addressed through the maximum likelihood function, a specialized statistical approach that determines the likelihood of observing a set of data in a hypothesized model. To explain how this works in IRT, one can suppose an item is well crafted and appropriate in its characteristics to a given examinee. The test maker presumes the examinee has a .5 chance of giving a correct response. This is expressed as syntactically as in Equation 1.

$$X = .5 \quad (1)$$

Next, the test maker can generalize this notion to a response (either correct or incorrect) to any item. Since the probability rests on ability, the generalization is written as follows.

$$P(U_i | \theta) \quad (2)$$

Equation 2 is read as the probability (P) of a response (U) on any given appropriate item (i) is a function of ability (θ). Thus, for the hypothetical examinee in the description of Equation 1 taking the item presumed that $P(U_i | \theta) = .5$. Examinees of another ability level would have a different probability.

Tests are composed of more than one item, of course, so the probability function is extended to include a test of any length (n items). Now, the probability of a correct response is conditioned upon several items and is accordingly a joint probability, meaning the probability of a response on all the items. A joint probability is calculated as the probability of a response on the first item times the probability of a response on the second item, and so forth to n items. This is written in Equation 3.

$$P(U_1, U_2, \dots, U_n | \theta) = P(U_1 | \theta) P(U_2 | \theta) \dots P(U_n | \theta) \quad (3)$$

To see Equation 3 in action, the reader may imagine that a particular examinee has 3 items presented to him on a test: a perfectly suited item (one in which the probability is .5 for his ability), another that is very easy for his ability (with, say, probability of .8), and a third item that is difficult relative to his ability, say, probability is .4). The joint probability of responding correctly to all the items on this short test is .16 (.5 x .8 x .4), or about 16 percent. Determining item characteristics is similarly

done with a likelihood function, but this time using the examinee's presumed ability to inform an item's characteristics.

The mathematics of solving likelihood equations involves calculus and is not easily done when there are many items on a test. However, if the metric is in log units, the calculations are much simpler. Adding a small constant to the log-produced results yields answers that are nearly identical to what would be acquired in normal metric. Hence, most IRT calculations are done in log metric, and the θ scale is expressed in log units, called *logits*.

The mathematical expression for the 3PL, in logistic units, is as follows.

$$P_i(\theta) = c_i + (1 - c_i) \frac{e^{D_{a_i}(\theta - b_i)}}{1 + e^{D_{a_i}(\theta - b_i)}} \quad i = 1, 2, \dots, n \quad (4)$$

While Equation 4 appears formidable, it is straightforward. In the equation, most terms are already known, including the probability (P), as well as the a, b, and c parameters. The e merely denotes that the expression is in log units of base e, and the D is a scaling constant to allow the results of log units to closely approximate a normal metric.

From this point on, IRT is mostly a search process wherein examinee responses to items give search to item characteristics and estimated item characteristics search for the best fitting examinee ability. When the process is

complete, the test maker knows both IRT ingredients: examinee ability and item characteristics.

IRT is a powerful route to estimating an examinee's ability on the tested construct as well as learning about characteristics of test items. For these reasons, it is commonly used in many national testing programs such as the NAEP (National Assessment of Educational Progress), the SAT (Scholastic Achievement Test), GRE (Graduate Records Examination), LSAT (Law School Admission Test), MCAT (Medical College Admission Test), and many other assessment programs.

J

JAMES, WILLIAM 1842–1910

William James, often referred to as the Father of American Psychology, was born in New York City on January 11, 1842. As a youth, he was educated in private schools and had a succession of tutors in Europe and the United States. In 1864 he entered the Harvard Medical School, where five years later he received his medical degree, the only degree James ever received.

In 1873 James was offered a post at Harvard teaching physiology. His acceptance signaled the start of a prestigious career, for James was to become a gifted teacher, skilled orator, and prodigious thinker and writer. In 1875 he established the first laboratory of experimental psychology in the United States, and a year later he became the country's first professor of psychology. "The first lecture in psychology that I ever heard," he later wrote, "was the first I ever gave." In 1878 he married Alice Howe Gibbens. They had five children. His brother Henry became a famous novelist.

The Principles of Psychology, a two-volume work that had taken James 12 years to complete, was published in 1890. At the urging of his publisher to create a book with greater classroom appeal, James later condensed the two volumes into one, *Psychology: The Briefer Course* (1892). The complete work came to be known as *The James*, and the abridged tome as *The Jimmy*. For years, the two served as the standard psychology texts for generations of American university students.

The dawn of the 20th century found James at the height of his eminence both in philosophy and psychol-

ogy. *The Will to Believe* (1897) and *Varieties of Religious Experience* (1902) reflected his growing spiritual and philosophical concerns. In 1907 he published *Pragmatism*, a concept that identified one of the prevailing philosophical movements of the 20th century. A method for resolving philosophical disputes, pragmatism aimed to discover the truth of an idea and to consider its value in terms of its practical, ethical/moral, and intellectual consequences.

James was the first American psychologist to directly address educational concerns. In July of 1892, he delivered the first of 12 lectures on psychology to teachers in Cambridge under the title of "Talks on Psychology of Interest to Teachers." Published in 1899 as *Talks to Teachers on Psychology*, the book became popular with educators, who subsequently used it prominently in teacher training programs throughout the world.

In *Talks*, James urged educators to familiarize themselves with the needs and interests of their students so that teaching practices could be geared to helping students develop the habits and make the associations and connections necessary to ensure effective learning. Progressive for its day, James's approach offered a view of teaching and learning in which freedom and compulsion each play an appropriate role. His educational psychology abounds with references to rigor, effort, ambition, competition, pugnacity, and pride.

The impact of James's ideas on modern educational psychology has been profound. In 1903 John Dewey referred to James as the "spiritual progenitor" of the progressive education movement launched at the University of Chicago. His emphasis on the importance of habit

William James THE LIBRARY OF CONGRESS.

and associations on human functioning influenced the behaviorist movement in psychology, but when humanistic psychologists searched for an antidote to behaviorism, they too stumbled on to James and his plea for a psychology centered on the individual and receptive to the importance of self-processes and introspection. Albert Bandura's social cognitive view of reciprocal determinism is also indebted to the Jamesian view of human functioning in which individuals and environments influence each other reciprocally.

Emphasis in the early 2000s on the importance of self-processes such as self-concept and self-efficacy in education is rooted in the critical aspects of self-awareness and personal cognition that James believed vital to the study of psychology. Moreover, 21st-century interest in conceptual change can be traced to James's vivid description of this process. Interest and research on habit (subsequently referred to as automaticity) also continues to

thrive. Additionally, motivation researchers are active in their study of Jamesian concepts such as interest, attention, memory processes, modeling and imitation, and transfer. Modern theories of constructivism can also be traced to James's theory of knowledge.

After his retirement from Harvard in 1907, James was in constant demand for lectures. In 1909 he published *A Pluralistic Universe* and *The Meaning of Truth*. Soon, however, his health began to deteriorate. On August 26, 1910, cradled in the arms of his wife Alice, William James died of an enlarged heart. He was 68. Two years after his death, a number of his articles were published as *Essays in Radical Empiricism*.

K

KNOWLEDGE

One of the main goals of cognitive psychology is to understand the relationship between knowledge and learning. To do so, researchers developed the *information processing model* (IPM) in the early 1950s, which has been used as the modal model of cognition since that time. The IPM consists of three main components, including sensory memory, working memory, and long-term memory (Neath & Surprenant, 2003). Sensory memory processes incoming sensory information for very brief periods of time, usually one-half to three seconds. The amount of information held at any given moment in sensory memory is limited to five to seven discrete elements such as letters of the alphabet or pictures of human faces. Working memory refers to real-time information processing in which meaning is assigned to incoming information from a text, pictures, or math problem. Long-term memory refers to a permanent repository of knowledge in memory. To use a computer analogy, sensory memory corresponds to inputting information via the keyboard, working memory corresponds to information current on the computer screen, and long-term memory corresponds to the computer's hard drive.

CATEGORIES OF KNOWLEDGE

Information processing theory assumes that ongoing mental activity in working memory is aided by different types of information in long-term memory that supports thinking and problem solving. At least three categories of knowledge are stored in long-term memory, including declarative, procedural, and self-regulatory knowledge (Anderson, 1976; Tulving, 1972). Declarative knowledge refers to the

facts and concepts. Procedural knowledge refers to how to do things. Self-regulatory knowledge refers to knowledge individuals have about themselves as learners, what they know, and how to control their learning. All three types of knowledge are important. However, even large amount of declarative and procedural knowledge, without self-regulatory knowledge to support it, does little to help people survive and adapt successfully.

Declarative knowledge is a broad category that includes facts, concepts, and the relationships between concepts that lead to an integrated conceptual understanding of a domain of knowledge. Declarative knowledge includes thousands of facts such as the names of colors, numbers, coins, and trees. Concepts consist of two or more units of factual information that are used to understand a broader phenomenon such as human rights or social justice. Often concepts are phenomena that can be described abstractly, such as freedom or happiness, even though these phenomena do not exist in the physical world. Declarative knowledge also includes integrated conceptual knowledge that is sometimes referred to as *structural knowledge* or *mental models* (Halpern, 2003).

One of the most important organizational units in memory is the *schema*, which refers to an organized body of information about some distinct domain of knowledge. For example, every adult has a "car schema" in which information about different types of cars is organized. A car schema could be organized in several ways using either the cost or size of the car to generate subcategories. Anyone asked to name a luxury car could quickly name cars such as Rolls Royce or Bentley as examples. Most other people who share the same cultural group would have this information organized in a similar way as well.

Procedural knowledge is knowledge about how to do things, ranging from simple action sequences such as brushing one's teeth, to complex actions such as driving a car. Most adults possess an enormous amount of procedural knowledge, which enables them to perform complex activities such as grocery shopping easily because those procedures are automated through practice. Although there are many different types of action sequences, there are three sequences of special importance, including complex scripted actions, algorithms, and heuristics that are stored as single entities in memory.

Scripts refer to extended action sequences and plans that are stored in memory as single units of knowledge. Each person possesses thousands of scripts, for activities such as getting dressed, driving a car, dining at restaurants, and social interactions that save enormous amounts of time because scripts can be activated intact from memory. Scripts are analogous to schemata. Whereas schemata help individuals organize declarative knowledge about a topic or domain, scripts help people organize and remember steps in a complicated action sequence. Algorithms and heuristics can be thought of as "mini-scripts." An algorithm is a rule for solving a specific problem that always works, whereas a heuristic is a rule of thumb for solving a problem that often works, but not always. For example, an algorithm could be used to compute the average of 1,000 scores by adding all the scoring and dividing the total by the number of scores. A simple heuristic could also be used to estimate the average by sampling seven scores at random, rank ordering the scores, and using the middle score as an estimate.

Self-regulatory knowledge is knowledge about how to regulate one's memory, thought, and learning (Schunk & Zimmerman, 2006). Declarative and procedural knowledge alone are not sufficient to be an adaptive learner. In addition, individuals must possess knowledge about themselves as learners and about the skills they need to learn effectively. Self-regulatory knowledge can be divided into two types, including domain specific knowledge and domain general knowledge (Alexander, 2003). The former is knowledge individuals possess about themselves with regard to a domain such as mathematics or a sub-domain such as geometry. In contrast, the latter includes general knowledge such as learning strategies that enable people to adapt and self-regulate across all domains.

Domain specific knowledge refers to knowledge that is encapsulated within a particular domain of learning such as mathematics, history, and literature. Sometimes domain specific knowledge is referred to as *topic knowledge*, although this term suggests knowledge about a specific topic such as geometry within a broader domain such as mathematics. Domain specific knowledge is extremely important in the development of expertise and skilled

problem solving (Ericsson, 2003). Cognitive psychologists once believed that it was possible to capture the knowledge of experts through interviews and observation, and in turn, help novices become experts quickly. However, researchers discovered that experts become experts slowly through years of hard work, deliberate practice, and guidance from other experts. Most experts have deep knowledge in one domain, yet shallow knowledge in other domains, due in large part to the amount of time they invest in developing expertise in their chosen domain. Expertise in one domain usually does not transfer spontaneously to other domains, although it can be facilitated through direct instruction and analogical cues, which help the learner understand the relationship between two different problems.

Domain general knowledge refers to knowledge that is equally useful to learners across domains and topics. Domain general knowledge often is referred to as *metacognitive knowledge*, which includes knowledge of cognition and regulation of cognition (Schraw, 2006). The former includes strategy knowledge and conditional knowledge, while the latter includes knowledge of regulatory skills such as planning, monitoring, and evaluation of learning. Metacognitive knowledge enables learners to identify problems and self-correct by changing strategies.

TEACHER KNOWLEDGE

Like other experts, skilled teachers possess different types of knowledge that facilitates classroom practice. Shulman (1987) suggested that skilled teachers possess knowledge about domain content, pedagogy, learners and student development, as well as educational contexts, and educational ends, purposes and values. Many educators view content and pedagogical knowledge as essential to effective teaching. Content knowledge refers to knowledge in a particular domain, such as mathematics, science, social studies, reading, and language arts. Pedagogical content knowledge has been defined as "a collection of teacher professional constructions, as a form of knowledge that preserves that planning and wisdom of practice that the teacher acquires when repeatedly teaching a certain topic" (Hashweh, 2005, p. 273).

Content knowledge is domain-specific in nature, whereas many teachers have endorsed domain-general pedagogy that emphasizes constructivist teaching. The fundamental idea of constructivism is allowing students to connect to the learning environment through problem-based learning, inquiry activities, and dialogues with others. By allowing students to construct knowledge as learners, the educational goal is to help them think critically about concepts. There are many strategies that a teacher might employ when teaching a particular content areas: (a) scaffolding, which allows

the learner to make sense of complex tasks; (b) modeling, which requires the teacher to think aloud about problem solving; while (c) coaching, guiding, and advising requires the teacher to probe the students' thinking. Experiences should be genuine and relevant to the learners and inquiry is used as an approach for students to engage in discovery learning.

IMPLICATIONS FOR LEARNING AND TEACHING

Knowledge facilitates information processing and long-term learning by providing an integrated conceptual network of information in long-term memory. Knowledge in isolation (i.e., inert knowledge) is of little value, whereas organized knowledge is powerful because it enables people to sort and store information in memory, predict and judge, and evaluate their learning accurately. Knowledge also enables individuals to process information more efficiently (Neath & Surprenant, 2003).

Recent research emphasizes the importance of constructed knowledge, distributed cognition, and distributed knowledge. *Constructivism* refers to the assumption that knowledge is constructed actively by learners, rather than transmitted passively through lecture, discussion, or observation. Constructivism assumes that active learning is better because knowledge is understood in a deeper, more relevant way. An extension of constructivism is the assumption that knowledge and learning are more sophisticated when mutually shared across multiple learners in an active dialogue. This is referred to often as *distributed cognition*. In contrast, *distributed knowledge* refers to knowledge that is distributed across two or more individuals, but may be distributed across hundreds of individuals, such as knowledge about complex technological products. Knowledge can also be distributed between humans and human artifacts such as books and tools such as calculators.

Distributed cognition and knowledge are topics of considerable debate for both practical and theoretical reasons. Many educators assume that mutually constructed meaning is more dynamic than individually constructed meaning, and some believe that knowledge exists only as a distributed set of beliefs and assumptions across multiple individuals (Zhang & Patel, 2006). In addition, many have argued that complex ideas and knowledge require multiple contributors to exist at all. From a theoretical standpoint, researchers are interested in how to best foster distributed cognition across multiple people and/or machines, and how to represent knowledge in human and machine databases in a distributed manner.

Like students, teachers possess different types of knowledge that are essential to effective teaching (Shulman,

1987). Teachers develop this knowledge slowly over time, often taking 5 to 10 years of teaching practice to develop deep expertise. Both students and teachers construct most higher-order conceptual knowledge through personal experiences, reflection on experiences, and dialogue with other students and teachers (Ericsson, 2003). Individuals also construct metacognitive knowledge that enables them to self-regulate within their domain of expertise. Constructed *executive knowledge* is assumed to be stored in long-term memory in sophisticated schemata and scripts that enable the individual to perform a variety of complex skills with a high degree of efficiency.

KNOWLEDGE REPRESENTATION

Knowledge representation refers to how knowledge is stored in long-term memory. Researchers have been keenly interested in this topic for over 50 years and a number of models of knowledge representation have been developed (Miyaki & Shah, 1999). There are four main families of models that are of interest to researchers. These include network, production, dual coding, and connectionist models. Each model is summarized below, compared to other models, and briefly discussed regarding its contributions to understanding learning in the classroom.

NETWORK MODELS

Network models of knowledge representation became popular in the 1960s. Early models focused on the hierarchical representation of declarative knowledge in memory and the relationship between different knowledge units (Quillian, 1968; Collins & Quillian, 1969). Network models possess three major components, including nodes in which a specific unit of information is stored, properties of information within nodes, and relational links among nodes. This can be explained by reference to the domain of animals. Subsumed within this domain are different types of animals such as birds, fish, and mammals. Network models envisioned each of these categories as nodes, while each node possessed a number of essential properties. The “animal” node included properties such as “breathes, eats, has skin.” The “bird” node included properties such as “has wings, has feathers, and flies” whereas the “fish” node included different properties such as “has fins, has gills, and swims.” Network models emphasized parsimony in mental representation; thus, properties included in a superordinate node were not replicated at a subordinate node. Because birds and fish are both animals, it was not necessary to include the property “has skin” because this property was included already in the “animal” node.

Quillian (1968) proposed five different kinds of relational links between nodes, including superordinate and subordinate, modifier, disjunctive, conjunctive, and residual links. These links specified whether properties of one node were shared with another node. For example, the fact that all animals have skin is a superordinate link that is true of all other links subsumed beneath it unless otherwise noted as a disjunctive link. Network models based on the notion of nodes, properties, and links helped explain how people remember information in an efficient manner and why it is relatively easy to search memory and make simple judgments, such as whether a canary eats and has skin.

The search process of memory was explained by the concept of spreading activation of attention among nodes.

Some concepts activated particular nodes and activation would spread to adjacent nodes. For example, the word “camel” would activate the “mammal” node and all properties of mammals would be activated, whereas properties of distance nodes such as fish would not be activated. Thus, activation spread through memory both vertically and horizontally. Activation spread vertically in an upward (i.e., camel to mammal) or downward (i.e., camel to dromedary). Activation also spread horizontally (i.e., camel to horse, camel to mule). Activation typically spreads further in a horizontal versus vertical direction, although activation is constrained in part by the situational demands of learning.

The idea that memory is organized into nodes of specific information that are interrelated to other nodes has been a lasting idea. Almost all other models of knowledge representation incorporate the idea of node, although what a node includes varies from model to model. The assumption that nodes have properties and are linked in a manner that indicates the type of relationship between nodes has not fared as well. Early network models provided a useful description of how declarative knowledge was represented in long-term memory, but they failed to explain the construction and representation of procedural and self-regulatory knowledge. Network models also paved the way for the development of schema theory in the 1970s, which spawned hundreds of practical experiments about the effect of schemata on learning and memory.

In recent years, a new class of network models has appeared that focuses on higher order processes such as complex problem solving, creativity, and metacognition (Griffiths, Steyvers & Tenenbaum, 2007). These models frequently describe excitatory and inhibitory processes similar to those described in connectionist models. This new breed of semantic network models often provides a better account of complex mental processes, such as understanding the overall gist of text or conversation.

PRODUCTION SYSTEM MODELS

Production models of knowledge representation and learning were first developed in the 1970s. One goal of these models was to explain a broader array of memory phenomena such as procedural learning, in addition to the representation of declarative knowledge. The most comprehensive production model is the ACT-R model (Adaptive Character of Thought, Revised) by John Anderson (1996, 2000). Anderson’s model developed from the human associative learning (HAM) model proposed by Anderson and Bower (1973).

ACT-R proposes three interactive memory systems that support adaptive thinking, including declarative knowledge, procedural knowledge, and working memory. The declarative knowledge component consists of schemata

and chunks within schemata that encode specific declarative knowledge units. The procedural knowledge component consists of production rules that break down complex action sequences into a number of “if-then” steps, which enable the learner to perform complex actions using a series of simple steps. Declarative and procedural components are connected to each other, as well as a working memory system in which activated declarative and procedural units are used to solve problems, make decisions, and adapt to environmental conditions.

ACT-R differs from earlier network models in that it proposes production rules, which are combined into production systems, which enable the brain to represent complex actions. A production rule specifies the action to be taken to achieve a specific goal and the conditions under which each action is taken. For example, imagine that a person has a ring of five keys and needs to open an office door. This scenario can be represented as a simple production as follows: IF a person must open a door, THEN he or she must insert key one and open the door; IF key one fails to open the door THEN the person must insert key two, and so on.

This production rule could be subdivided further into finer grained production rules that specify how to use each key until the correct key is identified, or none of the keys open the door. In addition, conditions could be added to each substep in the production sequence to assist the learner. For instance, one might add a condition statement, instructing the person not to attempt to use long, narrow keys with square heads because these keys often open car doors rather than office doors.

Anderson states that complex cognitive activity can be understood and explained in terms of small productions, based on simple units of declarative and procedural knowledge. This suggests that learning is a systematic process of acquiring declarative and procedural knowledge through experience and using this knowledge under specific conditions to execute complex actions, which themselves are comprised of many small productions. The theory of ACT-R also discusses how individuals construct and infer new knowledge based on past experiences. Thus, the theory is not entirely experience driven. Nevertheless, ACT-R views learning as a systematic process of acquiring the right knowledge and using that knowledge under the right conditions. Using knowledge repeatedly (i.e., practicing) increases the speed and accuracy of productions. Tuning productions to varying conditions also increases the efficiency of learning and performance.

Like network models, ACT-R postulates a process of spreading activation among declarative and procedural knowledge units during the execution of production sequences. Anderson (1996) provides sophisticated weighting systems, which serve as algorithms for which production

rules to apply under particular conditions. Activation spreads among production rules as a function of conditions and weights, which highlight some rules and downplay others. Activation is not necessarily hierarchical from superordinate to subordinate nodes, as is often the case in network models. Thus, production systems tend to be less hierarchical than networks.

Production system models have two clear advantages over earlier network models. First, they incorporate procedural knowledge into the model and explain how procedural and declarative knowledge are interrelated through working memory. Second, they do an excellent job of explaining incremental skill acquisition and the development of expertise. Production systems have been used to create and model intelligent tutoring systems that might take the place of human tutors. One potential criticism is that production systems are highly mechanistic; that is, they postulate that learning and performance is the sum and nothing more than the sum of a sequence of discrete productions. Related to this criticism is the fact that production systems highlight the role of experience and direct leaning and downplay rational reflection and the role of discovery and creativity.

DUAL CODING MODELS

Dual coding theory (DCT) was first postulated by Alan Pavio in the early 1970s and continues to be an important model of processing and knowledge representation in long-term memory (Pavio, 2007). DCT postulates two separate modular stores in long-term memory that include visual-spatial and verbal representation systems. Both systems are assumed to be functionally separate, yet interconnected. This means that visual-spatial and verbal long-term memories can perform tasks independent of one another, yet are able to pool resources when necessary. A number of researchers have speculated that dual-coding systems may be reflected in neurological differences between the brain’s right and left hemispheres (Pavio, 2007). DCT also postulates that some learners may have a visual-spatial or verbal preference for information processing.

DCT hypothesizes different representational systems for each of the two codes. The visual-spatial system uses mental images as the primary representational code, while the verbal system uses speech as the primary code. DCT assumes that every object and concept has a verbal label in verbal memory, whereas not every object or concept has an imaginal label in visual-spatial memory. Specifically, some concepts such as “automobiles” have concrete referents, while some concepts such as “affection” do not. DCT refers to this distinction as concrete versus abstract concepts.

The most important assertion of DCT is that concrete concepts may be easier to process and learn because mental activity can be distributed across the two stores

Four models of knowledge representation in long term memory				
	Network	Production system	Dual coding	Connectionist
Type of architecture	Hierarchical	Non-hierarchical production rules	Modular; two separate modules	Non-hierarchical distributed neural networks
Important components	Nodes, properties, relational links	Production rules and systems of rules	Verbal and visual-spatial stores networks	Units (explicit and hidden); weighted connections; neural networks
Important processes	Spreading activation	Spreading activation	Separate storage systems with separate resources	Activation; forward and back propagation
Strengths	Simple; does good job of modeling hierarchical relationship of declarative knowledge	Models procedural knowledge. Explains development of expertise	Explains differences in visual vs. verbal processing and recall	Modeled after brain physiology. Can be tested using computer simulations. Generalizes to other life forms.
Weaknesses	Does not explain procedural, conceptual or self-regulatory knowledge	Mechanistic. Places strong role on experience and practice rather than reflection.	Does not explain integrated visual-verbal representations.	Very data-driven Removes "mind" from learning.

Table 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

(Reed, 2006; Sadoski, 2005). Thus, a word such as “cat” can be represented separately in each storage system, whereas a word such as “truth” presumably is represented only in the verbal system. Two implications follow from this assumption. One is that information that is concrete in nature or that can be visualized will be better learned (Sadoski, Goetz, & Rodriguez, 2000). This has led to a great deal of research on the use of mnemonic techniques. A second implication is that visual information such as pictures in a book, summary tables, graphs, charts, and other visual aids should facilitate learning (Schnotz, 2002).

Research findings generally support the two-store model proposed by dual coding theory. DCT seems to be especially useful as an explanation of beginning reading processes such as vocabulary learning. It also explains why words are easier to learn in context as well as in the presence of visual aids such as pictures. In contrast, the theory does not explain well how congenitally blind individuals learn or how students create integrated visual-verbal representations in memory.

CONNECTIONIST MODELS

Connectionist models of knowledge representation and learning became popular in the 1980s and sometimes are referred to as neural networks or parallel distributed processing (PDP) models (Neath & Suprenant, 2003). Connectionist models represent an important paradigm shift from network and production system models because they de-emphasize the intentional role of the learner, while emphasizing the role of experience in building neural pathways and connections, as well as assumptions about cognitive architecture (Bechtel & Abrahamsen, 2002).

Although a great deal of attention has been devoted to connectionist models the past 20 years, especially the seminal work of Rumelhart and McClelland (1986), their origin can be traced to earlier researchers such as Selfridge (1959).

Connectionist models differ from network and production models in two ways. The first difference is that previous cognitive models used a computer metaphor to describe human information processing. In this view, information passes through an initial sensory system, is acted upon in working memory, and represented in permanent store in long-term memory. Connectionist models replaced the computer metaphor with a neural pathway metaphor modeled on the human brain. In this view, information is represented as patterns of activation across a variety of units, which correspond to neurons in the human brain.

A second difference is that network and production models focus on the representation of discrete units of information within a node in memory (e.g., a fact or a simple production rule), whereas connectionist models view knowledge representation as continuous across a number of interconnected units in memory. Thus, information such as facts, concepts, and production rules are not represented within single nodes, but distributed across nodes.

Connectionist models propose a rather simple architecture based on units, which maintain elementary information, typically simpler than corresponding nodes in network and production models. Multiple units are connected to create information that one might label as facts or concepts. The connectivity pattern among these units is of utmost importance. Any given unit may be connected to

many other units, using a number of different connectivity patterns. Thus, one unit may be part of different knowledge representations much like a single light in a theatre marquee may be used to spell different words. Connectionist theories have proposed different types of units. The most important of these are input units, output units, and hidden units, which are mediating connections between inputs and outputs.

Each unit has an activation value assigned to it under different processing conditions. Activation spreads throughout the system, but depends in part on the connectivity pattern among units, as well as connection weights, which determine whether one unit contributes more activation than another unit. There are a variety of activation algorithms; however, the two most important are forward (i.e., input to output units) and backward propagation (i.e., output to input units). Training (i.e., learning) in a connectionist network occurs as units are activated and deactivated, and connection weights change due to environmental conditions and feedback to the connectionist network through back propagation.

Connectionist models have several strengths and weaknesses. Strengths include their close physiological analogy to the human brain, the fact that their major claims can be tested using computer simulations, and that they provide a general theory of learning that is not unique to humans, but explains how learning may occur in other mammalian and non-mammalian life forms. Possible weaknesses, depending upon one's theoretical point of view, is that connectionist models are too bottom-up (i.e., learning occurs exclusively through experience and data-based feedback), and the mind is removed from models of learning (i.e., the role of rational reflection and inference construction is downplayed).

COMPARING THE FOUR MODELS

Each of the models described above has unique strengths. Table 1 provides a summary of these, as well as the main assumptions of each model. Several points should be considered regarding Table 1. First, each of the models is speculative and incomplete in nature. A large number of studies have supported some, but not all, of the assumptions of each of the models. Currently, there are few cross-model comparisons that definitely support one of the four hypothesized representational architectures. Second, all of the models emphasize the bottom-up nature of learning from experience. Network models are most likely to emphasize the role of higher-order knowledge, whereas connectionist models are least likely to make assumptions about higher-order knowledge or conscious self-regulatory skills. Third, all have useful implications for understanding learning.

IMPLICATIONS FOR LEARNING

Theories and models of knowledge representation all agree on two important implications for learning. One is that knowledge is represented in complex, multi-dimensional ways in memory. The models in Table 1 assume that learners possess higher-order knowledge that develops from simpler knowledge representations. In addition, all the models assume that knowledge is modular in nature (i.e., partitioned in memory into functional units), albeit each model postulates different modules such as concepts embedded in schemata (i.e., networks), separate declarative and procedural representations (i.e., production systems), or imaginal and verbal processing systems (i.e., dual coding).

A second implication is that knowledge is acquired very slowly. Concepts, schemata, and procedural skills are built up slowly over time, automated over hundreds of hours of practice, and often honed under the watchful eye of mentors and master teachers. From an educational perspective, it seems naïve to expect students to become highly knowledgeable within a domain without years of exposure and practice within that domain. Observing and modeling the performance of an expert helps novices develop the knowledge and skills necessary to perform at a high level of expertise.

One important difference among the four perspectives described above is how they address very complex representations such as mental models (Radvansky, 2006). A mental model is a cognitive representation of a complex process (e.g., flying a jet), spatial map (e.g., mental navigational map of New York City), or explanatory model of some phenomenon (e.g., Big Bang Theory). Many experts would agree that constructing mental models and using them to reason and solve problems is the height of cognition. Nevertheless, it is unclear presently how individuals construct mental models, represent them in memory, or use them to make complex decisions (Dougherty, Franco-Watkins, & Thomas, 2008). Network and production system models seem better suited to explain them, whereas connectionist models often deny the necessity of complex representations like mental models. Understanding the representation of complex mental phenomenon such as a mental model remains an important goal of cognitive psychology.

KOHLBERG, LAWRENCE **1927–1987**

Lawrence Kohlberg (1927–1987) was a psychologist who drew on education, anthropology, and philosophy, to inform his work on the development of moral judgment and on moral behavior. Kohlberg was raised in Bronxville, New York, and attended Phillips Academy, an elite board-

Lawrence Kohlberg. BARRY DONAHUE. COURTESY OF HARVARD OFFICE OF NEWS AND PUBLIC AFFAIRS.

ing school. After World War II he assisted in smuggling European Jewish refugees to Palestine. This work, a turning point in Kohlberg's interest in morality, was documented in his first article, "Beds for Bananas" (1948). At the age of 21, Kohlberg enrolled as an undergraduate at the University of Chicago and earned his bachelor's degree within a year. Kohlberg continued studying at the University of Chicago in pursuit of a degree in clinical psychology; he was inspired by Jean Piaget's work to interview children and adolescents about morality, which was the focus of his dissertation. Kohlberg completed his doctoral degree in 1958. He held a faculty position at the University of Chicago department of psychology for six years before joining the Graduate School of Education at Harvard in 1968. Kohlberg was devoted to developing his research and mentoring students at Harvard until his death in 1987.

Kohlberg's work was particularly influenced by the philosophies of Socrates, John Locke, Thomas Jefferson, and John Stuart Mill, as well as the works of Jean Piaget and John Dewey. Just as Socrates thrived on dialogue and

conflict, Kohlberg viewed such interactions as essential for his development. Thus, many of his critics could also be considered his collaborators. Most notably, this group includes feminist psychologist Carol Gilligan, who began teaching at Harvard with Erik Erickson in 1967. After meeting her in 1968, Kohlberg invited Gilligan to collaborate on a study and, in 1970, to become his teaching and research assistant. Colleagues and friends, the pair coauthored a book and several papers. In 1982, Gilligan authored *In a Different Voice*, in which she challenged Kohlberg's work by calling for the inclusion of female populations and women's perspectives in morality research. Though at odds with each other in their publications Kohlberg and Gilligan continued to teach together, actually teaching about their disagreements.

Kohlberg's initial contribution to educational psychology set the stage for the remainder of his work. Previous theories on morality assumed that society or adults imposed morality on children or that moral judgments were based on avoiding negative feelings. In contrast, Kohlberg asserted that children are moral philosophers whose ability to formulate their own moral decisions develops with experience. For his doctoral dissertation, Kohlberg interviewed 72 White Chicago boys about the Heinz dilemma: Heinz, a man without the means to buy the drug necessary to save his wife's life, steals the drug from the pharmacist. Based on the boys' responses and influenced by Piaget's theory of developmental stages, Kohlberg identified six stages of moral judgment development contained within three levels. The preconventional level includes stage 1, punishment and obedience orientation, and stage 2, instrumental relativist orientation. The conventional level includes stage 3, interpersonal concordance orientation, and stage 4, society maintaining orientation. The postconventional or principled level includes stage 5, social contract orientation, and stage 6, universal ethics principles. Seeking to validate his theory, Kohlberg developed an interview protocol and scoring guidelines (moral judgment interview) and gathered longitudinal and cross-cultural data. These studies included a 22-year study with data collected every three years and over forty studies conducted in Western and non-Western countries. Generally, these studies found support for Kohlberg's theory.

Although widely known for his theoretical and empirical work, Kohlberg focused increasingly on practical applications of his work. He consulted on and created moral education programs for schools, universities, prisons, and community organizations. The most radical of these programs was his "just community approach" in which organizations are fully democratic. Kohlberg helped several schools adopt this approach in which every student and

staff member has an equal voice, and an equal vote, in every school decision. One decision at the Cluster School in Cambridge, Massachusetts, allowed students to leave school early if there was no elective course they wanted to attend. Elsa Wasserman, a Cluster School counselor, reported that the students felt a rare sense of commitment to the school and to fellow students due to the just community approach.

The impact of Kohlberg's work is not that he provided a definitive answer to a particular psychological question, but that he breathed new life into the formulation of questions and the pursuit of answers. Kohlberg brought a new perspective and new methodology to moral development inquiry and encouraged students and colleagues to challenge his and others' work by bringing their own perspectives to bear on issues. Thus, whereas Kohlberg's theory of moral development is so highly regarded that it is included in nearly every psychology textbook, Kohlberg's work as a whole energized the field, actually diversifying the perspectives and approaches represented in the moral development research conducted by other researchers.

LANGUAGE IMPAIRMENTS

SEE *Speech and Language Impairments*.

LAVE, JEAN 1939–

Jean Lave is a social anthropologist, whose work on learning as an integral aspect of social practice has been a major influence on thinking in several fields, including cultural studies, sociolinguistics, organizational studies, human geography, and of course education. That so many disciplines have been influenced by her work speaks to the power of her insights.

Born in 1939, Jean Lave received her BA in anthropology from Stanford University and her PhD in social anthropology from Harvard University. She has taught at the University of California at Irvine and at Berkeley. She has done fieldwork research on the nexus of social practice, learning, and identity in a variety of settings, including Indian communities in Brazil, tailor apprentices in Africa, and shoppers in the United States. Subsequently, in the context of an ethno-historical study of the port trade undertaken with Paul Duguid, Lave investigated the complex identities of British families in Portugal (see the book *History in Person*). She has received several awards, including in 1994 the Sylvia Scribner Research Award from the American Educational Research Association in recognition of the influence of her work on thinking and research in education.

Those who have had the privilege to work with her know Lave as an exceptional teacher and collaborator, who practices her theorizing and invests in it her deep concern about the social production of marginalization. For her, in both her theory and her life, the production of knowledge is a fundamentally social enterprise. The book *Understanding Practice*, which she edited with Seth Chaiklin, reflects this ability to open spaces for learning together: It was the result of a highly collaborative two-part conference, during which a group of scholars met initially without position papers, but collaborated until a major contribution had been published.

Lave is best known for her seminal writing on situated learning, which she describes as “changing participation in changing practices.” In their book *Situated Learning*, she and Etienne Wenger introduced the now widely adopted concepts of “legitimate peripheral participation” and “communities of practice.”

But it is important to place these contributions in the context of Lave’s intellectual trajectory. On the one hand, these developments were the result of two decades of careful studies of learning as situated in activity. Early in her career, Lave did an ethnographic study of apprenticeship among Vai and Gola tailors in Liberia, a study summarized in *Situated Learning* and analyzed in more details in a subsequent book *Apprenticeship in Critical Ethnography*. This ethnography convinced Lave that knowing and learning had to be understood as situated in the activities and trajectories of the apprentices whose new skills were part of their becoming tailors. Back in the United States, she applied the insights of the tailor study to understand the use of mathematics by shoppers in grocery stores. This study examined the complex relations

among persons in action, social contexts, and knowledgeability, and yielded an insightful critique of purely cognitive perspectives on learning laid out in her groundbreaking book *Cognition in Practice*.

On the other hand, communities of practice and legitimate peripheral participation are not isolated concepts. They are part and parcel of a broader framework, a learning theory anchored in a “historical, dialectical, social practice theory.” (Lave, 1996, p. 150) This theory places learning in the context of the lived experience of persons in the socially constituted world with its histories, cultures, institutions, identities, generations, claims to knowledge, and their contested production and reproduction in communities of practice. A person always participates in multiple communities of practice, and learning entails the development of an identity across practices.

Turning this theoretically and ethnographically informed gaze on the classroom, Lave questions some fundamental assumptions about schooling. She uses insights from apprenticeship to challenge the privileged status of teaching and to argue that learning, not teaching, is the primary phenomenon for both students and teachers learning as the fashioning of a trajectory of identity. Listening to students, she hears them talk about the work of entering their social reality rather than school subjects. She suggests that to advance teaching, “teachers need to know about the powerful identity-changing communities of practice of their students, which define the conditions of their work” (Lave, 1996, p. 159).

Her focus on social practice provides both a theoretical framework and a body of field research to analyze the classroom as a unique place of practice, with its own logic, politics, and history. This yields three fundamental questions about classroom teaching:

What is the practice of the classroom as a historically specific setting for learning?

How is the practice of the classroom related to “mature practices” in the world?

How is the practice of the classroom related to the everyday lives of students more broadly?

That these three questions seem natural to educators in the early 2000s is a tribute to the influence of Jean Lave.

LEARNED HELPLESSNESS

Learned helplessness results from experiencing uncontrollable events that cause individuals to expect future lack of control. It is characterized by decreased motivation, failure to learn, and negative emotions such as sadness, anxiety, and frustration. The learned helplessness response pattern was discovered accidentally during the mid-1960s in the study of animal learning: Psychologist Martin Seligman observed that after exposure to inescapable electric shock some dogs passively accepted the shock even when they could take action to turn it off. The so-called helpless dog puzzle initiated decades of research and theory on learned helplessness that covered various topics, including passivity in laboratory rats, clinical depression, children’s classroom behavior, success in selling insurance policies, and mortality in nursing homes.

Learned helplessness is formally defined as a disruption in motivation, affect, and learning following exposure to noncontingent (uncontrollable) outcomes. There are three crucial elements to its definition: contingency, cognition, and behavior. Contingency refers to the objective relationship between actions and outcomes; for helplessness to occur there must be no relationship between a person’s actions and the outcome he or she experiences. Cognition refers to how individuals perceive the contingency, explain it, and extrapolate from this understanding. The perception of uncontrollability (noncontingency) may be accurate or inaccurate, but once it occurs individuals attempt to explain it. From this explanation they make extrapolations about the future and, when learned helplessness occurs, they expect that their behavior will not influence future outcomes. Behavior refers to the observable effects of being exposed to uncontrollable outcomes. Most often it involves a sense of giving up weaker attempts to control the situation or even failure to try to do so at all—a behavior incompatible with new learning. The response is also accompanied by negative emotions such as anxiety and sadness.

LEARNED HELPLESSNESS IN CHILDREN

It was not long before the idea of learned helplessness was extended to child behavior. In the early 1970s, Carol Dweck demonstrated that some children adopted the view that once failure occurred the situation was out of their control and that there was nothing they could do. Specifically, she used children's explanations for failure on a questionnaire to study two groups, those who viewed failure as due to insufficient effort and those who did not. She was able to document two response patterns to failure by having fifth and sixth grade students talk out loud while attempting problems too difficult for their age level immediately after successfully solving age-appropriate problems. She labeled the patterns learned helpless and mastery oriented.

The learned helpless pattern, shown by children whose questionnaire responses did not invoke insufficient effort for failure, involved denigrating their abilities upon encountering failure, overestimating the number of problems they did not solve, and expressing considerable self-doubt. Their performance deteriorated as they were less likely to solve problems after experiencing failure even when the problems were identical to those solved before the failure. Integral to this response pattern is the experience of negative feelings, including anxiety, sadness, and expressed boredom. Thus, the helpless pattern comprises a reaction to failure that undermines the self and impairs performance.

The mastery oriented pattern, in contrast, leads to increased motivation in the face of failure. Children who demonstrate this response pattern typically show some form of self-instruction or self-monitoring when they encounter failure. Their mood remains positive and they maintain the belief in their ability to perform well. Their optimistic view is matched by their behavior as most (over 80%) maintain or improve their problem-solving strategies and they solve just as many, or more, problems as they did prior to experiencing failure. In sum, these children view failure as a challenge and as a learning opportunity, not as an indictment of their ability.

These response patterns show that the differences are not due to ability. Children who display learned helpless versus mastery oriented patterns perform equally well prior to encountering failure, but those who are mastery oriented show superior performance following a failure experience. About 80% to 85% of all students clearly demonstrate one of the response patterns with students of all abilities falling into each group. It is therefore not uncommon to find very intelligent, bright students who are learned helpless, a group that is all too easily overlooked in the classroom.

LEARNED HELPLESSNESS IN THE CLASSROOM

Because the patterns described were identified in rigorous experimental studies, it is important to note that they have also been shown to occur on typical classroom tasks. Specifically, children who encountered confusing instructions in a questionnaire booklet in the classroom performed differently on subsequent questions depending on whether they fell into learned helpless or mastery oriented groups. Under these circumstances, the number of children answering all questions correctly was lower for those showing the learned helpless response pattern (34.6%) as compared to the mastery oriented pattern (71.9%). When, however, the instructions were clear, there was no appreciable difference in the performance of helpless (76.6%) and mastery (68.4%) groups.

Learned helplessness in the classroom can result from teacher behavior. This discovery emerged from the observation that girls in grade school receive higher grades and less negative feedback in the classroom than boys. Although the feedback girls receive confirms their

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

competence they tend to question their ability in the face of failure, putting them at greater risk of displaying learned helplessness. In an attempt to address this conundrum, Dweck and colleagues observed the pattern of evaluative feedback given to boys and girls in grade school classrooms (Dweck et al., 1978). They found that the contingencies of feedback differed in that 45% of boys' work-related feedback referred to its nonintellectual aspects (e.g., neatness) whereas for girls the feedback referred almost exclusively to its intellectual quality. Teachers also more frequently ascribed boys' failures to lack of motivation. They then conducted an experiment to show that both boys and girls who received the teacher-girl contingency were more likely to view subsequent failure feedback from that evaluator as indicative of their ability.

The teacher-boy feedback pattern allows boys to avoid ascribing failure to their ability and to even blame the teacher for negative feedback, allowing them to enter a new grade with high expectations of success. This option is less likely for those experiencing the teacher-girl contingency as the areas of academic performance remain similar; hence, failure attributed to lack of ability will remain relevant. If correct, boys should be able to enter a new grade level with higher expectancies for success as compared to girls, but these differences should decrease as children experience evaluation from the new teacher. This is precisely what Dweck, Goetz, and Strauss (1980) found when expected success was assessed at the beginning of a school year (October) and later in the year (December).

There is some evidence that the learned helpless and mastery oriented patterns are socialized by parents. For example, parents who attribute their children's failures to their children's ability tend to have children who display helpless behaviors (Fincham & Cain, 1986). Observation of third grade children and their mothers performing a series of solvable and insolvable problem-solving tasks showed that mastery oriented children had mothers who increased task-focused teaching behaviors and maintained high-positive affect during the insolvable puzzles, whereas mothers of children showing learned helplessness reciprocated their child's negative affect. Similarly, when children mentioned performance goals, mothers of the learned helpless group responded by focusing on performance, whereas mothers in the mastery oriented group redirected attention by focusing on a learning goal (e.g., "Let's see if we can figure out a pattern here").

IMPLICATIONS OF LEARNED HELPLESS FOR EDUCATORS

Attempts to remediate learned helplessness have largely focused on changing the ability attributions associated

with learned helplessness to effort attributions (e.g., "Work harder and you'll do better"). These attempts efforts have met with limited success possibly because little attention has been given to the perceived credibility of the feedback. When credible, such feedback likely increases motivation, but it may be demoralizing if not credible. Effort attribution feedback is likely most successful in the early stages of learning and for difficult tasks, when greater effort can produce better results and its credibility is high. However, Dale Schunk has found that ability feedback (e.g., "You're good at this") given when children succeeded early in the course of learning enhanced achievement better than effort feedback.

Although feedback that focuses on controllable attributions (e.g., effort, strategy use) is widely recommended, research suggests that focusing students' attention on the goal of learning rather than on showing how well they can perform has beneficial effects in combating helplessness. Success obtained in attempts to remediate learned helplessness responding has occurred largely in short term interventions, and it remains to be determine how best to produce lasting changes. In view of evidence that a relationship develops over time between learned helplessness patterns and children's achievement level (Fincham, Hokoda, & Sanders, 1989), there is an urgent need to address this gap in researchers' knowledge.

LEARNING AND TEACHING FOREIGN LANGUAGES

Although a large proportion of the world's population speaks two (or more) languages, the psychological study of second/foreign language learning is not commonplace. Typically, courses in second language learning are not offered in departments of psychology; thus, few students ever have the opportunity to avail themselves of such knowledge. This is unfortunate because psychology has much to offer to the field of foreign language instruction. Almost everyone has studied a second language at some time in their schooling, but only a few psychologists have developed a specialized interest in learning and teaching a second language (e.g., Bialystok, 2001; Hakuta, 1986; Hamers & Blanc, 2000; Rivers, 1964; Krashen, 1981).

The relevance of second language learning and teaching for psychology is as critical as any topic having to do with the intricacies involved in any aspect of human learning. The goal here is to discuss a few of the psychological questions involved in second language learning and to provide a theoretical and empirical understanding for why the learning and teaching of foreign languages is a legitimate area of work for psychologists (see McLaughlin, 1987; Padilla, 2006). This discussion will be framed around key questions in the field of language education.

METHODS FOR TEACHING A NEW LANGUAGE TO STUDENTS

Over the years many methods for teaching a new language have evolved. The most longstanding method and the one that has been most heavily influenced by the work of psychologists is the Audio-Lingual Method (Rivers, 1964). The goal in this method is to overlearn the target language through communicative drills directed by the teacher. The idea is to use the target language to the point that it becomes automatic and in the process new habits in the language are formed that overcome the tendency to rely on first language habits. In this method new vocabulary and grammatical structures are presented through teacher-directed dialogue drills, as well as heavy reliance on language lab drills organized around imitation and repetition drills. Students' correct responses are positively reinforced. Listening and speaking in the second language are the objectives in this method. Students' native language habits are considered as interfering, thus the use of the native language is restricted in the classroom. This method emphasizes proper pronunciation, simple everyday dialogues, and correct grammar.

In recent years there has been a gradual shift in language education to an approach that favors communicative competence in the second language. This is

called the Communicative Approach. The goal of this approach is to teach students the new language through classroom activities that engage students in the process of negotiating meaning in everyday conversations, rather than in teacher-directed repetitions of contrived dialogues. Students are taught to be communicators, not learners merely of vocabulary and grammar as in the audio-lingual method. In this approach to teaching a new language, the emphasis is on developing motivation to learn through establishing meaningful, purposeful things to do with the new language (see Padilla, 2006). Individuality in using the new language is encouraged, as well as cooperation with peers, which promotes a sense of personal competence in the use of the target language.

DEFINING FOREIGN LANGUAGE AND SECOND LANGUAGE EDUCATION

The social context in which a new language is learned is the deciding factor in determining whether the new language is identified as a foreign or second language. For example, a program that teaches students English in school in the United States is referred to as English as a second language (ESL) instruction. However, in the same school and down the hall from the ESL classroom, a teacher may be instructing students in Spanish, French, or Japanese. Because these languages are not the primary medium of communication in the United States, students in these classes are learning a foreign language (FL). The distinction is subtle but important. English language learners (ELLs) are immersed in English and get much more authentic English input from native speakers than students learning a foreign language (e.g., French) since this is not the medium of everyday communication in the United States. Thus, English learners have many sources (e.g., peers and mass media) and opportunities for receiving English language input. In contrast, students learning a foreign language in an American school typically have only their teacher to rely on for authentic language input. The distinctions in language learning contexts are important because they reveal how language instruction is planned and implemented.

An important contrast between foreign language education and English language instruction is that in an FL class students are not expected to develop proficiency in one or two years of instruction. Even students who reach the advanced placement level in an FL are seldom capable of showing a high level of oral proficiency in the FL. However, in ESL instruction students are expected to be mainstreamed into English-only classrooms within one or two years. For many learners this is an unreasonable expectation that often creates other related school achievement difficulties. Thus, expectations differ depending on whether the discussion is about learning a second or a foreign language.

ELEMENTS INVOLVED IN LEARNING A SECOND LANGUAGE

Language learning is complex, whether the language is acquired in infancy as a first language or later in life as a second or third language. The learning process consists of acquiring a language system, rather than learning a series of disconnected components. A language system consists of not only grammatical rules and vocabulary, but also the proper way to use language, such as requesting information, inviting a friend to a social event, thanking a person for a kind act, or greeting a stranger. In addition, a language system includes discourse, whereby speakers learn what to say to whom and when.

In their research on bilingualism, Hamers and Blanc (2000) studied how bilinguals carry out a large variety of cognitive tasks in the two languages. Bilingualism involves having a command of the linguistic system—the phonology, morphology, syntax, semantics, and pragmatics that constitute the essence of each language, but it also means being able to keep the languages separate cognitively when necessary, and strategies to search the memory store in one language in order to use the information in the other language.

The specific elements of the language system learned in a second language classroom vary by language. For example, the student learning Chinese or Farsi must learn an entirely new orthography, whereas students learning Spanish will only have minor differences in alphabets to contend with (Akamatsu, 2002). Some languages will have very different sentence structures compared to English; others will appear to be more familiar. However, familiarity with the language system alone is not enough to enable students to engage in successful communicative activities. Learners also acquire the strategies that assist them in bridging communication gaps that result from differences of language and culture. Examples of these strategies include circumlocution (saying things in different ways), using context clues, understanding, interpreting, producing gestures effectively, asking for and providing clarification, and negotiating meaning with others.

In language learning and teaching an important concept is comprehensible input. Students can only learn what they understand and in language teaching this means that the teacher must make content comprehensible. There is a theoretical debate about what exactly comprehensible input is and how it advances a learner's knowledge of a new language (Sanz, 2005). However, at a practical level teachers understand that with early to intermediate language learners, teaching for comprehension includes providing many nonverbal clues such as pictures, objects, demonstrations, gestures, and intonation cues. As competency in the language develops, other strategies include using hands-on activities and coopera-

tive or peer tutoring techniques. As learners' vocabulary and knowledge of the language expands, they are able to comprehend more information. Ultimately, mastery demands that learners understand what the teacher is saying in class or what a native speaker is saying in a real-life context as well as the appropriate conversational interactive exchanges in and out of the classroom. Sound strategies for teaching languages to students who differ by their level of proficiency have been incorporated into a compendium, "Standards for Foreign Language Learning in the 21st Century" (National Standards in Foreign Language Education Project, 1999). All of the professional language associations have endorsed the Standards and they are a critical element in teacher education programs today. In fact, education students must demonstrate mastery of these Standards in order to receive their teaching credential to teach a foreign language.

THE ROLE OF MOTIVATION

Gardner (1985) studied a variety of psychological and social variables in examining the role of motivation in second language learning. According to Gardner, anyone who seeks to learn a second language recognizes the potential value of speaking a new language and must be motivated to learn the language for one of two reasons: instrumental purposes (e.g., to get a job or to meet a school graduation requirement) or for integrative purposes (e.g., to understand better how native speakers of the language think and behave). Motivation underlies the learning of language because it addresses the goals and expectations of the learner as well as the teacher. If a person is only interested in enough survival skills in a new language to be able to secure employment then the level of attainment will be different from learners who want to read and discuss the important literature of another culture. In an extension of Gardner's research, Sung and Padilla (1998) found an "ethnic heritage-related motivation" for learning Chinese, Korean, or Japanese. Students who wanted to learn the language of their ancestors were more motivated to learn these more difficult languages, especially if their parents also wanted them to learn the language. Thus, knowing students' reasons for learning a second language enables teachers to plan an appropriate curriculum.

TIME INVOLVED IN LEARNING A SECOND LANGUAGE

How long it takes to learn a second language is an important pedagogical as well as psychological question because the answer depends in part on the learner's age, aptitude, personality, and motivation. If a person wants just enough language to be able to interact on a social level with native speakers, he or she will spend considerably less time learning the new language than a person

who wants to be able to succeed academically in a classroom in the new language and compete with native speakers.

The learning of basic survival communication skills in a new language takes a few months to a year or two depending on the amount of language input the learner receives from native speakers of the target language, the accuracy of second language output demanded by the context, the motivation of the learner, and the amount of practice in listening and speaking the new language. This depends too on the age of the learner. The knowledge of the new language that a child would need to interact with native speakers on the playground is different from what would be required of a university student who intends to study in Spain or China and take academic coursework in Spanish or Mandarin with native students. The time needed to master a second language for interpersonal communication is considerably less than the time required to master second language oral and literacy (reading and writing) skills in order to do academic level courses with native speakers of the second language.

In sum, there is no one answer to the question of how much time is necessary to learn a second language. The answer depends on expectations of what language skills (oral, listening, reading, or writing) and level of proficiency are desirable in the student. If the goal is basic survival skills, the amount of time needed will be far less than if the aim is to develop a high level of communicative competency.

ATTAINING PROFICIENCY IN A SECOND LANGUAGE

A learner who is proficient in a second language is able to exhibit a high level of accuracy in the second language. This includes being able to use the new language with grammatical accuracy in ways that are contextually and culturally authentic. Accuracy pertains to the precision of the message in terms of fluency, grammar, vocabulary, pronunciation, and cultural appropriateness. When language practice reflects real-world use, it forms the foundation for developing proficiency. This is true regardless of age, grade level, and type of language instruction offered the student.

The demands of accuracy in a second language, as can be seen, are high. There are four modes of expression—listening, speaking, reading, and writing—that constitute the paths by which information and concepts are transmitted from one person to another. Listening and reading are receptive skills; speaking and writing are productive skills. Students cannot create the language they are learning without first receiving input from teachers, peers, and the media. Thus, developing proficiency in each of these modes reinforces proficiency in the other modes. For

example, learning to read in a new language facilitates vocabulary acquisition, which augments speaking and writing in the second language. Thus, all four modes of expression are important elements in language learning, and their use is required in all formal classroom contexts.

Bialystok (2001) has shown that language input provided to language learners and the language output expected of them must be developmentally appropriate in two senses: (1) appropriate to the developing level of second language learning that the person has attained, and (2) appropriate to the cognitive and linguistic level of the student in his or her first language. In first language acquisition research shows that parents simplify their language input to their young children by speaking slower, frequent repetition, and simplified vocabulary and grammar. Hakuta (1985) argues that good language teachers use these same strategies in the early stages of ESL or FL instruction.

As the learner advances in the acquisition of the second language, three categories of discourse describe language use on the basis of receptive and productive skills. The categories are: interactive comprehension and production, receptive comprehension, and comprehensible production. Examples of interactive comprehension and production include telephone conversations and correspondence with friends through e-mail or instant messaging. These activities provide for an exchange of ideas. If one person does not understand the interchange, it is relatively simple to achieve understanding by seeking clarification. The interactive comprehension and production category of discourse is common in the social use of language.

Receptive comprehension refers to activities such as reading a book in a science class or viewing a video in a history class, activities that preclude seeking clarification from the author or narrator. In these situations, readers or listeners rely solely on their reservoir of concepts and language decoding skills for comprehension. Receptive comprehension becomes increasingly important with each grade level because students are required to do more reading and to integrate the information acquired with new knowledge presented by the teacher. Teachers are very important in this stage since they can provide valuable strategies to help students advance to more complex language structures.

Comprehensible production is critical because it shows what a learner is capable of doing in their new language (e.g., completing a job application, making an oral class presentation). During such activities the second language user makes a presentation or writes a letter that precludes any seeking of clarification of meaning by the reader or listener. This places a responsibility on the second language user to communicate with clarity and

accuracy. The comprehensible production category of discourse is common in the academic use of language. Further, many high-stakes tests (e.g., AP tests in a foreign language) include a writing component that requires students to produce an essay that is scored not only for grammaticality, but for the persuasiveness of an argument.

METHODS FOR TEACHING A SECOND LANGUAGE

Many strategies have evolved over the years to teach a second or foreign language to students. It is beyond the scope of this entry to cover all the methods that can be found in schools. However, two such methods used at the elementary school level will be described.

Foreign Language in the Elementary School. In this model a second language is presented as a distinct subject much like science or social studies—that is typically taught at least three to five times per week, with classes lasting anywhere from 20 to 50 minutes. Most FLES programs focus on teaching the four communication skills, as well as the culture of the speakers of the language being learned. Some programs called content-based or content-enriched programs incorporate themes and objectives from the regular academic curriculum as a vehicle for developing foreign language skills. Depending on the frequency and time devoted to language instruction and the opportunities provided for practicing the language, children can attain substantial second language proficiency.

Immersion Programs. Immersion programs have grown in popularity in Canada and the United States since the late 1970s (Padilla, 2006). In an immersion program English-speaking children spend part or all of the school day learning a second language (e.g., French, Spanish, Japanese). In a full (total) immersion program, students learn all subjects (e.g., math, social studies, science) in the second language. Partial immersion programs operate on the same principle, but only a portion of the curriculum is presented in the second language. Partial immersion programs are generally more common than full immersion programs. In this type of program students may learn social studies and math in the second language for part of the day, and science and language arts in English for the remainder of the day. In both full and partial immersion, the second language is the medium for the content instruction rather than the subject of instruction. Students enrolled in immersion programs work toward full proficiency in the second language and usually reach a higher level of language competence than students participating in FLES or other types of language programs. The research findings supporting this conclusion are well established.

In conclusion, there are many ways in which psychologists can contribute to the study of foreign language teaching and learning. Psychologists have much to give to educators and parents who want to know more about the latest research in cognition and language and how this applies to learning a second language.

LEARNING AND TEACHING MATHEMATICS

Major theoretical approaches to learning and teaching mathematics have been developed from three psychological perspectives of human learning. The *social constructivist approach* to mathematical learning emphasizes classroom learning as a process of both individual and

Doing a problem on the board helps students share solutions and strategies with the whole class. © TERRY VINE/CORBIS.

social construction. Critical to this framework is the need for mathematics teachers to construct a form of practice that fits with their students' ways of learning mathematics (Wood, Cobb, & Yackel, 1995). "The most basic responsibility of constructivist teachers is to learn the mathematical knowledge of their students and how to harmonize their teaching methods with the nature of that mathematical knowledge" (Steffe & Wiegel, 1992, p. 17). This is the planning whereby teachers plant powerful mathematical ideas in a personally meaningful context for students to investigate. Cobb, Wood, and Yackel (1993) further elaborate on teachers' responsibility in the mathematics classroom as playing the dual role of fostering the development of conceptual knowledge among students and facilitating the constitution of what is often referred to as taken-as-shared knowledge in the classroom community. This is the teaching in which, without direct access to one another's understanding, members of the classroom community achieve through social interaction a sense of some aspects of knowledge being shared, promoted by classroom social norms understood by members as constitut-

ing effective participation in the mathematics classroom community.

The underlying metaphor of social constructivism is *persons in conversation*, which highlights the critical role of language (see Ernest, 1996). For example, when teaching the theorem that the sum of the three inner angles of a triangle is 180 degrees, a teacher practicing social constructivism would present the idea of moving the three angles together to calculate the sum and would then have students talk about or share their ideas about moving angles. Manipulatives would be provided to students so that they could take a triangle apart and experiment with different ways of making three angles come together. Students would find that many of their ideas about moving angles would produce three angles forming a straight line indicating 180 degrees. This physical construction would then be followed by another "talk point" for students promoted by the teacher about how to move angles mathematically for geometric proof. Students, now with papers and pencils, would engage in continuing conversation about moving angles mathematically with

the main idea being creating equal angles in different places in order to pull three angles together (the mathematical construction would refer frequently to the physical construction). The language elements are always critical during the whole process from moving angles physically to moving angles mathematically.

The cognitive science approach to mathematical learning emphasizes the nature of knowledge representation (this separates cognitive psychologists from constructivist theorists). Representation in mathematical learning can take on different forms: cognitive (the internal representation of a learner's knowledge), mathematical (the mathematical representation of a mathematical structure), symbolic (the external representation of a mathematical notation), explanatory (the model and theory developed to account for cognitive structures and processes), and computational (the hypothetical mental representation in computer programs based on observed human behaviors) (see English & Halford, 1995). These representations provide a way to construct cognitive models of mental structures of mathematical knowledge and cognitive processes of mathematical learning. Cognitive processes operate on cognitive representations (mental structures) that are viewed as a network of interrelated mathematical ideas.

The quality of mathematical learning is measured through the number of connections that learners can make among mental representations and the strength of each connection (Hiebert & Carpenter, 1992). The notion of connected representation "provides an effective link between theoretical cognitive issues and practical classroom issues" (English & Halford, 1995, p. 13). Cognitive science has proven to be the most effective way to investigate problem-solving behaviors in mathematics. In addition to solid mathematical knowledge, successful problem solving in mathematics is found to require "a repertoire of general problem-solving heuristics" that remind mathematics educators of the classic work of Polya (1957) (English & Halford, 1995, p. 14).

For example, English and Halford (1995) argued that "a mental model of the relations between numbers themselves" is needed to truly understand numbers (p. 60). The mental model starts with a correspondence between a number and a set of objects (e.g., 5 corresponds to five apples). Relations between numbers can then correspond to relations between sets. Because the set of five apples has more objects (members) than the set of three apples, 5 is larger than 3. Students establish the mental model of number by experimenting with sets of objects to reinforce the correspondence between number relations and set relations. Without this mental model, most students would have to rely on the succession relation to understand numbers, with rote learning emphasizing the counting order of the numbers. Obviously, the notion that 5 is larger than 3 because 5 comes after 3 is at best vague and fuzzy to most students.

The sociocultural approach to mathematical learning emphasizes the effort to situate mathematical ideas within culturally organized activities. Because education is a process of enculturation (or socialization), it is important for learners to engage in social interaction with more knowledgeable experts in what Lev Vygotsky called the *zone of proximal development* and for teachers to use culturally developed sign systems and culturally appropriate artifacts as psychological tools for instruction (Vygotsky, 1978). "The qualities of thinking [and learning] are actually generated by the organizational features of the social interaction" (van Oers, 1996, p. 93). Internalization is another central notion in Vygotsky's cultural-historical theory of human development which "appears first between people as an intermental category and then within the child as an intramental category" (Vygotsky, 1960, p. 197-198). Particularly relevant to mathematics education is the notion that "learning is the initiation into a social tradition [of mathematical inquiry, mathematical discovery, mathematical argument, and so on]" (Solomon, 1989, p. 150).

With enculturation as the emphasis, a teacher who employs the sociocultural approach to teach mathematics would design a learning task through which students can interact with experts. Simply put, it is a process of guided participation and interaction of learning by solving problems just beyond a student's current capability with the help of a more expert other via scaffolding. Experts do not necessarily imply mathematicians. Teachers are most often the experts in real classrooms, and continuing professional development strengthens their expertise in mathematics. In addition, teaching assistants, advanced peers, and even parents can all be trained to become mathematics experts in real classrooms.

For the theorem that the sum of the three inner angles of a triangle is 180 degrees, experts would ask well-thought questions around the main idea of creating equal angles in different places so that the three angles can be pulled together to examine the sum. These questions prepare students for the demonstration of experts who would show students how to move one angle (both physically and mathematically), would have students comment on the move, and would ask students to move the other angles following a similar strategy. Observing students closely, experts would alert students of wrong moves, would point out reasons for wrong moves, and would demonstrate correct moves repeatedly. This modeling and coaching process between experts and students, often considered apprenticeship in nature, is the very foundation of the sociocultural approach that requires social participation and interaction of the whole classroom community. Finally, experts would evaluate with students on different strategies of moving angles and would reason with them on the best way to move angles.

The whole interaction between experts and students would end up with the establishment (or enculturation) of an important mathematical tradition (or practice) on the use of auxiliary lines for geometric proof. As a result, experts would have trained students on geometric proof in a way very similar to how masters would have trained apprentices in, say, furniture building.

LEARNING GOALS FOR MATHEMATICS EDUCATION

“Students must learn mathematics with understanding, actively building new knowledge from experience and prior knowledge” (National Council of Teachers of Mathematics [NCTM], 2000, p. 11). The mathematics education research community has been fairly united in identifying understanding as the major learning goal for mathematics education teaching mathematics for understanding. Simon (2006) stated:

Recent discourse in mathematics education has coalesced around the importance of focusing on and fostering students’ mathematical understanding. This agreement among mathematics educators has led to a commitment to generate new learning goals for students that are less skewed in favor of skill and facts learning and more focused on student thinking. (p. 359)

Although mathematics education has a long history, teaching mathematics for understanding is a fairly new notion.

Believing that two effectively different subjects are taught under the same name called mathematics, Richard Skemp published his classic paper on mathematical understanding in 1976. He distinguished between *instrumental understanding* (knowing how) and *relational understanding* (knowing both how and why). According to Skemp (1976), there are three advantages in instrumental understanding of mathematics: (a) easier to understand, (b) more immediate and more apparent rewards, and (c) quicker in getting correct answers. But the metaphor for instrumental understanding is *getting an instruction to go to a certain place* (i.e., still not knowing how to go to any new place). There are four advantages in relational understanding of mathematics: (a) more adaptable to new tasks, (b) easier to remember, (c) effective as a goal in itself, and (d) organic in quality. The metaphor for relational understanding is *getting a map to go to a certain place* (i.e., knowing how to go to any new place).

It is common among teachers to use rhymes to help students understand mathematical properties. Such an effort in many cases results in instrumental understand-

ing. For example, many teachers use the following rhyme to help students understand (or memorize) the order of number operation: *Please* (parenthesis) *Excuse* (exponential) *My* (multiplication) *Dear* (division) *Aunt* (addition) *Sally* (subtraction). Many students who have gained instrumental understanding through this teaching practice would mistakenly believe that, for example, they should do addition before subtraction because of the order shown in the rhyme. This rhyme does not illustrate the fact that there are equivalent levels of operation. The order of operation does not matter between multiplication and division. Neither does it between addition and subtraction.

In contrast to instrumental understanding, relational understanding aims to make students know the very reason behind every mathematical action (or manipulation). For example, when solving the equation $2X - 4 = 8$, for X , a teacher adopting instrumental understanding would procedurally have students move the 4 from the left side of the equation to the right side. Their instrumental understanding also reminds them to change the sign of the number (in this case from negative to positive): $2X = 8 + 4$ or $2X = 12$. However, many students have no understanding of why this rule governs this mathematical action. Instead of having students learn this procedural rule, a teacher adopting relational understanding would emphasize properties of equation operation, such as the one that adding the same number to both sides of an equation keeps equality. Therefore, students with relational understanding would perform: $2X - 4 + 4 = 8 + 4$ resulting in $2X = 12$.

Instrumental understanding produces procedural knowledge, whereas relational understanding produces conceptual knowledge. Hiebert and Lefevre (1986) defined conceptual knowledge as “knowledge that is rich in relationships . . . a network in which the linking relationships are as prominent as the discrete pieces of information” (pp. 3–4, cited in Simon, 2006). This is the reason why effective classroom teaching for mathematical understanding often emphasizes one key aspect of understanding: connection.

Researchers have increasingly recognized the importance of affect-related factors in mathematical learning and teaching. Stuart (2000) stated that “mathematics is like a sport: [performance is] 90 percent mental one’s mathematics confidence and 10 percent physical one’s mathematics competence in performing mathematical skills” (p. 330–331). After a review of studies, Eynde, de Corte, and Verschaffel (2002) noted that both affective and cognitive factors play a key role as the constituting elements of the learning process:

Motivation and volition (i.e., the conative factors) are no longer seen as just the fuel or the engine of the

REFORM AND CONTROVERSY IN MATHEMATICS INSTRUCTION

Between 1955 and 1975 mathematics education in the United States underwent major and expensive curricular reforms called “modern mathematics” or “new math.” The movement took various and sometimes contradictory forms with uneven implementation and outcomes. In 1989 the National Research Council (NRC) published *Everybody Counts: A Report to the Nation on the Future of Mathematics Education*. It identified some of the successes and failures of the reform movement:

- Some important aspects, such as a renewed emphasis on geometry, probability, and statistics, were widely adopted.
- Applications of mathematics to other fields, such as biology and business, became accepted components of mathematics curricula.
- Some attempts at deepening mathematical understanding, such as sets and commutative law, were poorly applied and became the butt of public ridicule.
- By moving the curricula into unfamiliar territory, teachers and schools lost the confidence of parents and the community.

Everybody Counts outlined some of the lessons learned from these attempts at curricular reform:

- The wholesale adoption by school districts of an intact outside curriculum is destined for failure.
- Superficial district wide curricular overhauls can be disastrous.
- Improvement in mathematics curricula and instruction requires a major public information campaign, strong leadership from teachers, parents, professionals, and politicians, and strong public support.

The NRC report identified ongoing transitions in mathematics education:

- from minimal mathematics for the majority of students and advanced mathematics for the gifted few to a common core of mathematics instruction for all students
- from an authoritarian “transmission of knowledge” to student centered “stimulation of learning”

- from public indifference or hostility toward mathematics to a recognition of its importance in contemporary society
- from a focus on routine skills to developing broad based mathematical abilities, including discerning relationships, logical reasoning, and using a wide variety of methods for solving new problems
- from preparation for subsequent math courses to topics with relevance for the present and future needs of students
- from an emphasis on paper and pencil calculations to the use of calculators and computers
- from a public perception of mathematics as a static set of rules to an appreciation of mathematics as an active science of patterns.

The National Council of Teachers of Mathematics (NCTM) published their landmark *Curriculum and Evaluation Standards for School Mathematics* in the same year as the NRC report. Among the NCTM’s recommendations:

- Voluntary acceptance of national standards based on the work of the NCTM to establish a common philosophy and framework for mathematics education
- Local implementation of reform involving the entire community
- The study of mathematics during every school year, including a broad range of mathematical subjects, the use mathematics in other classes, and the active engagement of students in learning
- The involvement of parents in demanding that schools meet the NCTM standards, encouraging their children to continue studying math, expecting homework to involve more than routine computations, and supporting teachers in curricular improvements
- An upgrading of the teaching profession, with teachers working together, familiarizing themselves with issues of mathematical education, examining current practice, and debating new proposals, and team teaching at the elementary level

- Designing appropriate assessments for future needs
- Strengthening college mathematics.

In 2000 the NCTM published *Principles and Standards for School Mathematics (PSSM)*, a refinement of the 1989 standards, outlining a common foundation for mathematics education for all students from preschool through grade 12. Its numerous recommendations for reform were generated from a set of principles:

- The Equity Principle: high expectations and strong support for all students, including an end to tracking that permanently excludes groups of students from a challenging comprehensive mathematics program to be replaced by structures that accommodate differences
- The Curriculum Principle: a consistent curriculum through the grade levels that draws on research for implementing standards and is chosen with input from families and the community
- The Teaching Principle: teacher understanding of what students know and need to learn and challenging and supporting them; teachers adapting to changing curricula and technologies and incorporating new knowledge about how students learn mathematics; improved pre service education, professional development, and collaboration
- The Learning Principle: students have time and opportunity to learn mathematics with understanding and to build on prior knowledge

and experience; elementary students study mathematics for at least one hour per day with well prepared teachers who enjoy math, including team teaching and the use of specialists; middle and high school students take the equivalent of one year of mathematics at each grade level, spending a substantial amount of time each day on work that keeps them engaged in mathematical learning

- The Assessment Principle: multiple forms of assessment that are aligned with instructional goals and provide teachers and students with useful information
- The Technology Principle: equitable allocation and utilization of technology that is embedded in the curriculum and enhances teaching and learning.

The *PSSM* stressed the urgent need for mathematics specialists to work with teachers, administrators, families, and community members.

In 2006 the NCTM published *Curriculum Focal Points for Prekindergarten through Grade 8 Mathematics*, which was at least in part a response to criticism that the *PSSM* had led to curricula lacking basic instruction in arithmetic. However controversy over new standards and teaching methods remained at least as heated as that over the new math in the 1960s and 1970s.

Margaret Alic

learning process, but are perceived as fundamentally determining the quality of the learning. In a similar way, self confidence and positive emotions (affective factors) are no longer considered as just positive side effects of learning, but become important constituent elements of learning and problem solving. (p. 14)

NCTM has been highlighting five new goals for mathematical learning and teaching since 1989 when it published the first-ever curriculum standards. Two of the five new goals are affective in nature: (a) students learn to value mathematics, and (b) students become confident in their ability to do mathematics.

CHALLENGES FOR EFFECTIVE MATHEMATICS INSTRUCTION

As early as 1985, Slavin and Karweit stated that “one of the most troublesome and enduring problems of mathematics instruction is accommodating heterogeneity in student

preparation and learning rate” (p. 351). The problem of classroom heterogeneity is much more pronounced in mathematics than in any other school subject because mathematics is structured in the most highly sequential fashion among all school subjects access to and performance in mathematics courses are determined by prior success in particular courses often referred to as prerequisites that systematically regulate student performance and progress in mathematics (see Oakes, 1990). This means that mathematical problems and difficulties accumulate, and the degree of classroom heterogeneity enlarges over time.

Traditionally, there are two ways to deal with the problem of classroom heterogeneity. One is ability grouping at various levels: (a) grouping students within a class (e.g., regular mathematics groups and advanced mathematics groups), (b) grouping classes within a school (e.g., curriculum tracking and curriculum placement), and (c) grouping schools within a district (e.g., special education programs and magnet programs for gifted students). The other

prevalent way to accommodate classroom heterogeneity is individualized instruction in which students work on learning materials at their own level and rate with frequent assistance from teachers.

NCTM (1989) introduced another means to accommodate diverse learning needs: *content differentiation*. This concept emphasizes that the depth to which a topic is explored should depend on the level of abstraction at which students are capable or operating. To apply this concept, classroom teachers make concrete examples and applications of a topic open to all students to learn but make higher levels of abstraction and generalization available to, but not required of, all students. Classroom heterogeneity remains a major challenge in mathematics instruction today because the effectiveness of ability group and individualized instruction has been challenged, and the concept of content differentiation is difficult to implement even for experienced teachers.

A related, but largely isolated, challenge in mathematics instruction is the presence, in some cases substantial, of English as a second language (ESL) students. ESL students face enormous difficulties in mathematical learning because both mathematics and the language that carries it are foreign to them. NCTM (1994) clarifies that all students, regardless of their language or cultural background, must study a core curriculum in mathematics based on its curriculum standards. In 1991 NCTM recommended five major changes in mathematics classroom to help ESL students succeed in mathematics: (a) selecting mathematics tasks that engage students' interests and intellect, (b) orchestrating classroom discourse in ways that promote the investigation and growth of mathematical ideas, (c) using, and helping students use, technology and other tools to pursue mathematical investigations; (d) seeking, and helping students seek, connections to previous and developing knowledge; and (e) guiding individual, small-group, and whole-class work (students benefit from a variety of instructional settings in the classroom).

EFFECTIVE INSTRUCTIONAL TECHNOLOGY FOR MATHEMATICS EDUCATION

Various types of instructional technology (IT) have been developed to enhance mathematical learning and teaching. Lou, Abrami, and d'Apollonia (2001) classified IT into five major categories according to its educational functions: (a) tutorial, (b) communication media, (c) exploratory environment, (d) tools, and (e) programming language (with limited application so far). Tutorial refers to programs that can directly teach mathematics by creating a stimulating environment in which information, demonstration, and practice are shared with students.

Computer-assisted instruction (CAI) and various mathematics games (e.g. Math Blaster) are typical examples. Research points to CAI as a potentially effective mechanism for teaching students (including those with special needs), with increased mathematics performance as positive outcomes (e.g., Xin, 1999).

Communication media refers to communication tools such as email, computer-supported-collaborative learning (CSCL) systems, videoconferencing, and the Internet. These tools promote effective communication and information sharing. Multimedia program and videoconferencing have begun to emerge as potentially effective tools for mathematical learning and teaching (e.g., Irish, 2002; SBC Knowledge Ventures, 2005). For example, videoconferencing is found to help meet state and national curriculum standards, reach new heights in staff professional development, and help students take classes not offered at their school. In particular, students involved in the operation of the videoconferencing equipment benefit the most by having learned both subject contents and technical skills.

Exploratory environment seek to encourage active learning through discovery and exploration. Logo, simulations, and hypermedia-based learning are typical examples. One of the hypermedia-based learning programs in mathematics is the Adventures of Jasper Woodbury, a mathematics program developed at the Vanderbilt University and widely used around the world. Based on the theory of anchored instruction, the program uses video and multimedia computing technology to provide problem-scenarios to help students develop skills and knowledge for problem solving and critical thinking. Implementation of this program has yielded positive findings (e.g., Mushi, 2000; Shyu, 1999).

Tools serve the technological purpose of making learning and teaching attractive, effective, and efficient. Word processors, PowerPoint, spreadsheet, Geometer's Sketchpad, data-analysis software, and various virtual manipulatives are typical examples. In mathematics classrooms, particularly at the elementary level, manipulatives are used extensively to help students build a foundation for understanding abstract mathematical concepts. Accessed via the Internet, virtual manipulatives are replicas of real manipulatives and capable of connecting dynamic visual images with abstract symbols (a limitation of regular manipulatives). A variety of studies have examined the use of virtual manipulative tools in mathematics classrooms and have found positive effects on student mathematics achievement and attitude toward mathematics (e.g., Moyer & Bolyard, 2002; Reimer & Moyer, 2005; Suh, Moyer, & Heo, 2005).

ASSESSING MATHEMATICAL LEARNING AND TEACHING

As an emerging concept, classroom assessment is different from student assessment in that the goal of classroom assessment is to understand learners' learning in order to improve teachers' teaching. Based on results of a comprehensive review of empirical research on whether classroom assessment can benefit learning (in mathematics, science, and English) by Black and Wiliam (1998), Harlen and Winter (2004) offered this summary:

[There is] convincing evidence that classroom assessment raises students' attainment when it has these key characteristics: that information is gathered about the processes and products of learning and is used to adapt teaching and learning; that learners receive feedback that enables them to know how to improve their work and take forward their learning; that teachers and learners share an understanding of the goals of particular pieces of work; that learners are involved in assessing their work (both self and peer assessment); that pupils are actively involved in learning rather than being passive recipients of information. (p. 390)

Some developments have also occurred in student assessment. There have been calls for traditional large-scale assessments not only to measure (or assess) but also improve (or support) student mathematical learning. Chudowsky and Pellegrino (2003) argued that large-scale assessments can and should do a much better job of "gauging student learning, holding education systems accountable, signaling worthy goals for students and teachers to work toward, and providing useful feedback for instructional decision making" (p. 75). As one of the efforts, large-scale tests are moving toward a closer alignment with mathematics curriculum and instruction.

Portfolios are emerging as a popular alternative student assessment. A portfolio is a purposeful collection of a students' work as indicators of their effort, progress, and achievement over time to gauge their cognitive and affective development. For mathematical learning, the purpose of a portfolio is to understand "student thinking, student's growth over time, mathematical connections, student views of themselves as mathematicians, and the problem solving process" (Stenmark, 1991, p.37). However, there ought to be a note of caution on alternative student assessments. Herman and Winters (1994) discussed the lack of empirical evidence on claims of advantages of portfolios over traditional student assessments. Carney (2001) noted that the research literature on portfolios did not change much from 1994 to 2001. An inspection of the leading *Journal for Research in Mathematics Education* shows again the lack of empirical research on all forms of alternative assessments since 2001.

RESEARCH GROUNDED CURRICULUM AND INSTRUCTION PROJECTS IN MATHEMATICS

After an evaluation of current mathematics curriculum projects based on his Curriculum Research Framework, Clements (2004) ranked the Realistic Mathematics Education (RME), the Investigations in Number, Data, and Space (Investigations), Everyday Mathematics, and the Connected Mathematics Project (CMP) as (large-scale) research-based curriculum projects in mathematics education. The RME actually is a learning and teaching theory about mathematics education, developed by the Freudenthal Institute in the Netherlands. Freudenthal (1991) views mathematics as connected to reality and as a human activity. "Realistic" refers not only to the connection of mathematics with the real world and everyday life but also to problems real in mind of students. The RME organizes mathematics education into a process of guided reinvention to allow students to experience the similarity between the process by which mathematics is learned and the process by which mathematics is invented. "Invention" emphasizes the need to develop steps in the learning process, and "guided" emphasizes the need to create an instructional environment for the learning process. The RME can be characterized as making good use of (a) contexts (phenomenological exploration), (b) models (instrument bridging), (c) productions and constructions from students (student contribution), (d) educational interactions (interactivity), and (e) intertwining (of various learning strands).

The Investigations is a complete K-5 reform-based mathematics curriculum developed under the leadership of Dr. Susan Russell at TERC in Cambridge, Massachusetts. It designs activity-based investigations to encourage students to think creatively, develop their own problem-solving strategies, and work cooperatively. In addition to talking, writing, and drawing about mathematics, students use manipulatives, calculators, and computers to explore mathematical concepts and procedures. Classroom assessment is embedded within each investigation for improvement in teaching. Studies are in favor of Investigations students in (a) straight calculation problems (basic facts and whole number operations), (b) understanding of number concepts and number relationships, (c) word problems and complex calculation problems, and (d) performance in a high-stakes standardized test (administered in Massachusetts). Studies also indicate that Investigations works well with students across all mathematics achievement levels.

Research and development of Dr. Max Bill and his colleagues during the 1980s and 1990s resulted in the University of Chicago School Mathematics Project. The major component, Everyday Mathematics, is a

research-based K-6 curriculum, with the goal to significantly improve both curriculum and instruction for all students to learn mathematics. The project began with a research phase in which a thorough review was conducted of existing research on mathematics curriculum and instruction with an emphasis on mathematical thinking. This review study was accompanied by interviews of hundreds of K-3 children and surveys of curricular and instructional practices in other countries. The research phase eventually established several basic principles to guide the curriculum development, including that (a) students learn mathematics from their own experiences obtained in an environment in which mathematics is rooted in real life, learners are actively involved in learning, and teachers provide learners with rich and meaningful mathematical contexts; (b) K-6 mathematics curriculum should build on an intuitive and concrete foundation, gradually shifting children to an abstract and symbolic foundation; and (c) teachers are the key factor in the success of any curriculum project, requiring adequate attention to their working lives.

Based on these principles, curriculum at each grade level went through a 3-year development cycle (1 year of writing, 1 year of extensive field testing, and 1 year of revising) with collaboration between mathematicians, education specialists, and classroom teachers. This unique development process has resulted in a comprehensive K-6 curriculum with a sequence of instruction carefully building upon and extending knowledge and skills obtained in the previous learning experience.

Led by Dr. Glenda Lappan at Michigan State University, the Connected Mathematics Project (CMP) is a research-based and field-tested middle school mathematics curriculum, different from many existing mathematics curricula because it takes a problem-centered curricular approach to develop powerful mathematical concepts, skills, and procedures with a focus on the ways of mathematical thinking and reasoning. CMP emphasizes the following principles reflecting both research and policy stances in mathematics education regarding what truly supports mathematical learning and teaching: (a) curriculum should be built around a number of "big" mathematical ideas, (b) underlying concepts, skills, or procedures should be in an appropriate developmental sequence; (c) an effective curriculum should be coherent connecting investigation to investigation, unit to unit, and grade to grade; (d) focus of classroom instruction should be inquiry and investigation of mathematical ideas embedded in rich problem situations, (e) mathematical tasks should be the primary vehicle for student engagement, (f) mathematical ideas should be explored deeply enough to enable students to make sense of them, (g) curriculum should develop student ability to reason effectively with information represented in multiple formats (graphic, numeric, symbolic, and verbal) and to

interchange flexibly among these representations, and (h) curriculum should reflect the information-processing capability of technology and appreciate how technology is fundamentally changing the way that people learn and apply mathematics.

Most reforms in mathematics instruction can be reasonably characterized as standards-based (referring to the 1989 NCTM Standards) and inquiry-oriented (referring to the hands-on and minds-on discovery approach). Different instructional reforms employ different strategies to promote standards and discoveries in mathematics. Some of them are research-grounded reforms, such as QUASAR (Quantitative Understanding: Amplifying Student Achievement and Reasoning), a national project particularly aimed at improving mathematics instruction for socially disadvantaged middle school students (see Silver & Stein, 1996). The most influential of the research-grounded instructional reforms in mathematics may well be the Cognitively Guided Instruction (CGI). Based on their research, Dr. Thomas Carpenter and Dr. Elizabeth Fennema at the University of Wisconsin at Madison led the development of the CGI approach to teaching mathematics (e.g., Carpenter, Fennema, Franke, & Empson, 1999).

Essentially, CGI encourages mathematics teachers to utilize what they know about the mathematical understanding of their students to select or create mathematical problems, promote students to think about the problems, stimulate students with a well-designed sequence of questions to guide them gradually to approach or discover the solutions, and facilitate discussion and idea-sharing throughout the entire instruction. The CGI instruction basics for teachers can be roughly summarized as: (a) giving sufficient waiting or thinking time for students to respond, (b) allowing free use of all materials to assist problem solving, (c) creating context of problem solving relevant to students, (d) reading a problem multiple times as necessary, (e) focusing on thinking process rather than product, (f) asking for and probing into students' explanations to learn about their mathematical thinking, (g) analyzing wrong answers from students with the whole class, (h) sharing solutions and strategies with the whole class, (i) promoting students to compare solutions to identify best problem-solving strategies, and (j) delaying symbol manipulations.

LEARNING AND TEACHING READING

Helping students become good readers is an important part of the education process. Students need to be able to gain information from a variety of texts, know how to access texts to solve problems, and be able to critically examine information presented through texts. However, providing reading instruction that develops such abilities can be a complex and challenging task. Therefore, this entry was designed to provide readers with some of the more prominent theoretical positions and instructional techniques that can be used to provide students with excellent reading instruction. This entry is meant to serve as a brief introduction and broad overview for teaching reading.

PREVALENT THEORIES IN READING INSTRUCTION

Exemplary reading teachers often have strong background knowledge in theories of reading and can apply them to their instruction (Pressley, Allington, Wharton-MacDonald, Block, & Morrow, 2001). Theoretical knowledge allows teachers to make more informed decisions about their instruction and helps them know why one technique may be better than another. Three theories are presented in this section: (a) schema theory, (b) socio-cultural theory, and (c) identity theory. Each theory offers a different way to understand the reading process and reading instruction.

Schema Theory. Schema theory states that individuals will draw on their knowledge of the world in order to help them understand what they read (Anderson, 2004). How well people can understand what they read is connected to the topic being presented and the amount of knowledge they hold about it. Different interpretations of text can result from different amounts and types of background knowledge on a given topic. Schemas exist for such areas as the content being presented in a text (people, ideas, and places), the processes for reading and comprehending (knowing how to identify words, summarize, locate the main idea), and for different genres of text (mysteries, autobiographies, web sites). Reading comprehension is likely to be limited if a person does

not possess sufficient background information for the information being presented.

Socio-Cultural Theory. Socio-cultural theory suggests that people's experiences at home, at school, and in their communities can influence their reading development. Students' views of reading, and the purposes of it, are often shaped at home before they enter kindergarten. When students read books or are asked to engage in reading activities, they draw on previous social and cultural experiences to help them understand what they should do and why. Students use their knowledge about what is valued to inform how they read and comprehend texts. Students from diverse cultural backgrounds may engage with reading activities in ways that are not valued by schools and that teachers consider unacceptable. Understanding that students' different approaches to reading are connected to their social and cultural backgrounds can allow teachers to provide more personalized assistance.

Identity Theory. Identity theory suggests that how students read texts and apply reading instruction will be connected to how they identify themselves as readers and how they want to be identified by their peers, teachers, or family members (Gee, 2002). In school, teachers often communicate what it means to be identified as a good or poor reader. Students who identify themselves as poor readers may disengage from reading because they are afraid that doing so will publicly reveal their weaknesses and allow a negative identity to be assigned to them. Teachers may interpret students' decisions as a desire not to learn and may respond by limiting the personal help they provide. Students who are identified as good readers or who show they are trying to become good readers are more likely to receive additional, personalized help.

IMPORTANT GOALS IN READING INSTRUCTION

An overall goal of reading instruction is to help students learn how to create new knowledge from what they read and apply it to specific problems in every day life. Helping students reach such a goal requires instruction in many small goals throughout their school careers. The critical goals in reading instruction discussed here are to develop students' (a) concepts about print, (b) phonics knowledge, (c) vocabulary knowledge, (d) fluency, and (e) comprehension abilities.

Concepts about Print. For beginning readers, developing concepts about print is often the first step in learning how to read. Concepts about print include understanding (a) about how to hold, open, and turn pages in books,

Because students' reading levels likely vary, the type of reading instruction they need also varies. RICHARD HUTCHINGS / PHOTO RESEARCHERS, INC.

(b) that text is read from left to right and top to bottom, (c) that printed words have meaning, and (d) there is a one-to-one match between spoken and written words (Tompkins, 2006). As students develop their concepts about print they learn how to interact with texts in ways that will help them gain meaning from them as they read. Students should have developed strong concepts about print by the end of kindergarten.

Phonics Knowledge. Phonics is the correspondence between letters and sounds (Stahl, 2002). Knowing the sound that the letter *s* makes and that this sound is different from the letter *n* is an example of phonics knowledge. Reading cannot take place without understanding the sounds letters make. Readers rely on their knowledge of phonics whenever they come across an unknown word and must sound it out.

Vocabulary Knowledge. Vocabulary knowledge is critical to students' success at reading. A central goal of vocabulary knowledge is to help students develop full word knowledge (Allen, 1999). Full word knowledge means

that students know multiple meanings for a given word and/or different ways a given word can be used. It is not necessary, or possible, to have full word knowledge for every word. For most words, students will have partial knowledge. They will know one definition for the word and be able to use it in a sentence. The more words students have at the partial and full knowledge level, the better their comprehension of text. Students who have limited partial and full word knowledge in the early grades often have reading difficulties later in school if their vocabulary is not fully developed.

Fluency. Fluency is the ability to read words accurately, quickly, and with expression (Rasinski, 2006). Students with poor fluency abilities read words slowly, in isolation, and often without any inflection. They tend to focus more on how to say the words and less on what the words in a sentence or paragraph mean. Students may read at faster or slower rates depending on the difficulty of the text being read, and their fluency abilities may change depending on the genre of the text being read. Most students should be able to read fluently by third grade.

Comprehension. Comprehending texts involves extracting meaning as well as creating it (Snow & Sweet, 2003). Students must be able to locate main ideas and facts within a text and use that information to further their understanding of a concept or idea. Comprehension strategies can be taught that assist students in making meaning from texts. Examples of comprehension strategies include visualizing, asking questions, and summarizing what was read.

CHALLENGES IN CREATING EFFECTIVE READING INSTRUCTION

Helping students meet the above goals requires providing them with effective reading instruction. Effective reading instruction, however, is not solely about teaching students a specific set of skills and providing opportunities for them to apply what they have learned. Teachers must often be responsive to numerous challenges, including (a) instructing students with a variety of reading abilities, (b) being able to differentiate instruction, and (c) finding appropriate texts.

In any classroom, teachers may have students reading on grade level as well as several years above or below. By fourth grade, many students are likely to be classified as struggling readers (Curtis, 2004). Struggling readers read one or more years below grade level but do not have an identified learning disability. They need additional comprehension instruction and texts on their current reading level (Allington, 2007; Duke & Pearson, 2002).

Because students' reading levels likely vary, the type of reading instruction they need also varies. Teachers need to assess students' strengths and weaknesses as readers and then create a plan of instruction that is appropriate for their needs. Not all students need the same type of instruction, read the same texts, or participate in the same activities. Such instruction requires a great deal of organization as well as detailed knowledge about assessment, cognitive reading processes, and reading instruction.

As teachers attempt to differentiate their instruction, they typically find that the textbooks they want students to read are too difficult for most of their students to comprehend, even those reading on grade level. Difficult texts can hinder students' abilities to learn content and improve as readers (Fordham, 2006). Teachers need to seek out additional texts that students can read and learn from with limited support.

EFFECTIVE TECHNIQUES IN READING INSTRUCTION

In teaching reading teachers can use a number of effective techniques. The techniques discussed here serve as an introduction to some of the more popular methods used in the early 2000s.

Word Walls. Word walls (Cunningham, 2000) are alphabetical lists of high-frequency words that are posted in the classroom. They help students develop their word recognition and fluency abilities. Walls are added to on a regular basis as new words are introduced. Examples of words that might be found on word walls are *a*, *no*, *of*, *she*, *has*, and *when*.

Repeated Readings. Repeated readings help to develop students' fluency, word recognition, concepts of print, and comprehension abilities (Topping, 2006). Students read texts or have texts read to them multiple times. When teachers read aloud, students can follow along, read aloud, or echo the teachers' words. Teachers may wish to point to the words as they read aloud. Students can also engage in repeated readings by reading with a partner or listening to a book on tape.

Centers. Centers allow students to practice previously taught reading skills on their own or with peers. Effective centers require students to read, write, and discuss what they are doing. For example, students might be asked to read a story on their own, create a written response, and then share and explain their response with a peer.

Guided Reading. Guided reading allows students to apply reading strategies they have been taught while reading texts that are an appropriate difficulty for them (Fountas & Pinnell, 1996). Teachers work with four to six students who need similar types of reading instruction. Teachers first introduce a text that students can read on their own with little support. Teachers may provide a brief lesson that focuses on one or two strategies they want students to apply when reading. Teachers observe the students reading and provide additional assistance as needed. As students progress, they read more difficult books and use more strategies.

Authentic Instruction. Authentic instruction (Duke, Purcell-Gates, Hall, & Tower, 2006) can improve students' comprehension of non-fiction texts and increase their understanding of text features such as headings, indexes, and table of contents as early as second grade. Students read and use non-fiction texts in ways that mirror how texts are used outside school. For example, students might choose to read non-fiction texts in order to answer their own questions about the world. Authentic instruction helps students learn how (a) to generate their own questions about a topic being studied and then (b) use a variety of texts to locate their answers.

Literature Circles. In literature circles, students come together in small groups to read and discuss a common text (Daniels, 2001). Students read a selected portion of

the text, complete a written response, and engage in a discussion with group members. Students' responses can include: (a) summarizing, (b) creating a picture, (c) making connections to other texts or experiences, or (d) developing meanings for new vocabulary.

Literature circles help students learn basic reading skills such as how to summarize and locate main ideas in texts. They also help students learn more complex skills, including how (a) to discuss how they made sense of a text, (b) support their interpretations of text, and (c) make connections across multiple texts.

ASSESSING READING ABILITIES

Assessing students' reading abilities allows teachers to understand their strengths and weaknesses as readers and can be used to inform reading instruction. The assessments presented here are ones that teachers can do on their own and with few materials. Each provides information about students' abilities as it pertains to one or more of the five goals discussed earlier.

Running Records. Running records assess students' fluency and word recognition abilities (Davenport, 2002). Teachers listen to students read a portion of text aloud. They place a check mark next to the words students read correctly and note any miscues made. Miscues are "unexpected responses that do not match the text" (Goodman, 1994, p. 1096) and are not considered to be mistakes. Miscues are based on students' current knowledge about the topic they are reading as well as how language is constructed. Teachers review their notes to examine what, if any, miscues students made when reading and look for patterns that may exist.

Retelling. Retellings provide information about how well students (a) comprehend passages, (b) can identify story elements in narratives, (c) can identify main ideas, and (d) can communicate the passage in an order that makes sense (Gredler & Johnson, 2004). Students read a text silently and then explain the text as though they were talking to someone who had never read it before. If students leave out information, teachers may ask them a question to see if they can identify a particular aspect and then note that the help was provided.

Informal Reading Inventories. Informal reading inventories (IRI) allow teachers to determine the level of text students can read on their own. They also provide teachers with information about students' fluency, word recognition, and comprehension abilities. IRIs allow teachers to develop a broader picture of students' abilities to read and comprehend text (Cooper & Kiger, 2008).

In an IRI, students read aloud a passage for which they can accurately read a minimum of 90 percent of the words. Students read individual word lists, written from a pre-primer through twelfth-grade level, to determine the level of the passage they should read. Teachers conduct a running record as the passage is read. Students then retell the passage. Finally, teachers engage students in a series of comprehension questions which range in difficulty. Students' responses to the questions can provide insight about how well they can locate basic facts in text and make inferences.

Narrative Comprehension. Narrative comprehension assessments help determine young children's abilities to comprehend narrative texts (Paris & Hoffman, 2004). The assessment can be used with children who may or may not be able to read. Students examine wordless picture books, explain what they think is taking place, and answer comprehension questions. The assessment shows how well children can recall important details from text, make inferences, and make connections across the story.

RESEARCH BASED CURRICULUM PROGRAMS

There are numerous research-based curriculum programs teachers can use for reading instruction. The ones described here help students develop the goals described earlier and also draw on many of the effective teaching techniques. Teachers may find that these programs provide ways to address some of the instructional challenges they may encounter.

Concept-oriented Reading Instruction (CORI). CORI increases elementary students' abilities to read science texts while increasing their science knowledge and motivation (Guthrie, Wigfield, & Perencevich, 2004). Students receive instruction on how to apply comprehension strategies to science texts and learn how such skills as summarizing, asking and answering questions, and locating information. As students read and learn about science, their intrinsic motivation, or personal desire to learn, is expected to increase. In the CORI program, students participate in activities, including (a) engaging with the world outside school, (b) reading a variety of texts, and (c) working with others. The CORI program follows a consistent pattern of instruction that is intended to help students develop in each of these areas.

Four Blocks. The Four Blocks program helps beginning readers learn how to read and can also assist students in third and fourth grade who may have reading difficulties (Cunningham, Hall, & Sigmon, 2000). It is made up of four different approaches that students experience each

day: (a) guided reading, (b) self-selected reading, (c) writing, and (d) working with words. The Four Blocks program was designed to help teachers work with students who vary in their reading abilities but without relying on ability grouping. The Four Blocks approach helps students develop their phonics, comprehension, and fluency abilities.

Open Court Reading. The Open Court Reading program is a commercially produced series of basals for students in grades K-6 (McGraw Hill, 2002). The reading program was based on research findings that support students' development as readers. Teachers can use a script when teaching lessons.

In kindergarten and first grade, the emphasis is on teaching decoding skills. The emphasis on decoding often results in students having strong decoding abilities and a greater understanding of sound-letter relationships. Beginning in second grade, a greater emphasis is placed on developing comprehension and fluency. The program is often criticized for failing to help students develop abilities to discuss texts and do more than comprehend at a literal level (Wilson, Martens, & Arya, 2005). However, Open Court has also been recognized for aligning its instruction with reading research.

LEARNING AND TEACHING SCIENCE

In 1983 the National Commission for Excellence in Education released its report, *A Nation at Risk*, announcing that U.S. schools had undergone a precipitous 20-year decline in the quality of mathematics and science education. The result was an intense new focus on research into how children learn science and how best

to teach it, culminating with the release of *Benchmarks for Science Literacy* (BSL) in 1993 by Project 2061 of the American Association for the Advancement of Science (AAAS) and *The National Science Education Standards* (NSES) in 1996 by the National Research Council (NRC) of the National Academy of Sciences. States and local school districts began instituting reforms and setting new standards.

However, after 15 years of standards-based reform American students exhibited little improvement in science achievement, and the achievement gap between majority students and economically disadvantaged and non-Asian minority students remained large. As the first decade of the 21st century neared its end it was apparent that 25 years of intensive research into learning and teaching science had not been effectively translated into classroom practice.

GOALS FOR SCIENCE LEARNING

Although there are ongoing efforts to encourage young people particularly females and minorities to pursue careers in science and technology, most researchers agree that the primary goal of K-12 science learning should be the creation of a scientifically literate population. Scientific literacy can be defined as a basic understanding of science, an appreciation of how science shapes society and culture, and the ability to reason scientifically. Many American adults lack the basic understanding of science that is required for making informed decisions about the many scientific issues affecting their lives. Therefore some educators go further, defining the primary goal of science education as providing students with the information and tools to become lifelong science learners who can adapt to the technological innovations that will be at the center of life in the 21st century.

For many educators learning goals have become synonymous with standards national, state, and local school district determinations of what students should know, understand, and be able to do in scientific subjects at specific grade levels. National standards are delineated in the BSL and NSES.

The 2007 NRC report, *Taking Science to School*, cites the development of scientifically proficient students as a key goal: "Students who are proficient in science:

1. know, use, and interpret scientific explanations of the natural world;
2. generate and evaluate scientific evidence and explanations;
3. understand the nature and development of scientific knowledge; and;
4. participate productively in scientific practices and discourse" (p. 36).

K-12 science education standards usually cite scientific thinking as a primary educational objective, and competence in scientific investigation as a goal from the earliest grades. According to these standards students should be able to:

- Formulate a question;
- Design an investigation;
- Analyze data;
- Draw conclusions.

HOW STUDENTS LEARN SCIENCE

It has been apparent since at least the late 1970s that traditional methods of teaching science lectures, textbooks, memorization of facts, theorems, and formulas have little to do with learning science. Furthermore with the explosion in scientific knowledge in the latter half of the 20th century, information was often obsolete before it could even be taught. Rather, a large body of research has clearly demonstrated that children learn science by doing science a process called inquiry-based learning, a form of constructivist instruction. With inquiry-based learning students investigate and discover on their own, in addition to reading and receiving instruction and guidance.

Inquiry-based science learning generally begins with observing, describing, and reflecting on objects and phenomena, leading to the formulation of questions and identifying assumptions about those objects and phenomena. Students then acquire more knowledge, using books and other sources to determine what is already known from experimental evidence. The next step in inquiry-based learning is to test explanations in a variety of ways. Students plan investigations and use tools to collect, analyze, and interpret data. They propose explanations, make predictions, and communicate their ideas, results, and conclusions.

Hands-on or exploratory learning stresses the importance of scientific experiences for developing skills. For young children these skills include observation and comparison, measurement, and classification, in addition to communication. More advanced skills involve inferring relationships, formulating hypotheses, and predicting outcomes. Students learn to identify and control variables, methods of gathering, organizing, and recording data, and how to draw conclusions.

CONCEPTUAL CHANGE

In contrast to the old-fashioned view that young children think in simple concrete terms, research has shown that the thinking of even very young children is quite sophisticated and that they are capable of thinking in both concrete and abstract terms. They utilize a range of reasoning processes including causal reasoning and

distinguishing between reliable and unreliable sources of information that form the basis of scientific thinking.

Perhaps most importantly a large body of research has shown that children do not start school as blank slates upon which scientific knowledge can be written. Rather, children come to school with their own conceptual resources, already knowing a great deal about the natural world and having formulated their own scientific ideas. However, children also vary greatly in their early learning experiences and opportunities, which may be influenced by race, ethnicity, language, gender, culture, and socioeconomic background. Thus they differ in their conceptual resources and in what they are capable of learning at a given age.

Because many scientific concepts are not intuitive, children often have deeply entrenched misconceptions about nature, and these misconceptions often prove to be barriers to learning science. In the late 1970s cognitive researchers began interviewing students to assess their understanding of scientific concepts. They found that many students had trouble, not because the concepts were inherently difficult, but rather because they conflicted with the students' entrenched misconceptions. Furthermore, the memorization of scientific facts and formulas could disguise these underlying misconceptions. Among the topics about which students often hold misconceptions are force and motion, the particulate theory of matter, heat and temperature, electricity, optics, and evolution.

Learning science requires not just knowledge of key facts and concepts but an understanding of how facts and concepts relate to each other and their implications and applications. This may require a large-scale reorganization of knowledge and in-depth conceptual change to overcome prior misconceptions. These processes take time and require that children work with the same ideas and concepts in different ways over weeks, months, and years. According to Posner and colleagues (1982), four conditions must be met for conceptual change to occur: Students must be dissatisfied with their current conceptions because they conflict with observations or contain discrepancies; students must understand the new idea; they must be able to reconcile the new idea with their own ideas; and they must find the new idea useful and amenable to further testing.

Strike, Posner, and colleagues' general model of conceptual change applied the philosophy of science to the learning of science. Since then the conceptual change approach has become a basic tenet of teaching science. By first assessing prior knowledge, students' knowledge can be built upon, and misconceptions and potential misunderstandings can be addressed. The goal is for students to discover or recreate concepts on their own. Posner and colleagues proposed that having students work through problems with different explanations and compare the results led the students to recognize the shortcomings of their explanations and strengthened the scientific concept.

FURTHER THEORIES OF SCIENCE TEACHING

In addition to the importance of conceptual understanding, most contemporary theories of science teaching involve support for constructivist practices active, inquiry-based, and collaborative strategies that utilize experimentation and other scientific methods to teach scientific reasoning within the context of specific science content. Because science is, in essence, a social process, research suggests that it should be taught as such, with emphasis on working in groups and whole-class and small-group discussions, questioning, and communication that enhance the development of scientific literacy.

Scientific discussions, explanations, and evaluation of evidence differ from those activities in other subjects and in everyday life. Students need instructional support to learn the language and practices of scientific experimentation, interpretation, and discussion. Many attempts at hands-on discovery learning have proved unproductive due to lack of guidance. In constructivist inquiry-based learning the teacher acts as a coach, introducing basic information and new concepts as required and guiding group discussions.

Finally, there is a consensus among researchers that science curricula, textbooks, national, state, and local standards and assessments contain far too many disconnected topics. Most research indicates that it is far more productive to focus on core ideas, which are explored in depth progressively through grades K-8.

EFFECTIVE INSTRUCTIONAL STRATEGIES

There exists a large body of research on effective means for promoting conceptual change. Building from misconceptions can be effective: For example, young children may find that their preconceived ideas about why weather changes conflict with their observations, so the teacher introduces the concepts of air movement and weather fronts. In a conceptual change approach the teacher provides an introduction, including a review and motivating experiences. This is followed by focus, in which the students observe an event, pose a problem, and formulate ideas and explanations. The challenge presents a conflicting question or discrepancy and the students then develop new ideas. Application involves solving problems using the new ideas and engages the students in discussion and debate. Finally, the teacher or students, or both, summarize the results and connect them with other lessons.

Discovery argumentation, using cycles of model-based reasoning, has been found to be effective with students from elementary school through high school. The *bridging analogies* strategy introduces a target situation in which the

students' initial intuition conflicts with a scientific principle. This is followed by an *anchoring intuition*, a situation in which intuition agrees with scientific principle. At first the students see the two situations as completely different. A series of bridging analogies or intermediate models are then presented in which the situations are intermediate between the target and the anchor. Following cycles of reasoning the students develop a new model that they can test. Nuthall found that upper-elementary students required three or four experiences with new scientific ideas before the concepts enter their long-term memory.

Know-Want-Learn (KWL) charts help students visualize what they already know and what they want to learn and then conclude with what they have learned. Hershberger and colleagues (2006) have modified KWL to Know-Learning-Evidence-Wonder (KLEW), emphasizing observation, evidence, and further investigation. Yet another variation includes "know and think," to encourage students to share their initial ideas and realize that what they think they know can change as a result of inquiry.

Research indicates that from the earliest grades designing and conducting experiments and investigations helps students understand scientific concepts. With guidance students can follow the scientific method by formulating hypotheses and designing and carrying out experiments and collecting evidence that is used to evaluate the hypotheses. This process conforms to several of the teaching guidelines presented in the AAAS's Project 2061 research-based *Science for All Americans* (1989):

- "Teaching should be consistent with the nature of scientific inquiry."
- "Science teaching should reflect scientific values."
- Scientific knowledge should be presented in the context of the processes by which it was arrived at.

Learning-cycle approaches can actively engage students in the processes of science through collaborative inquiry into interesting and familiar phenomena. First fully described in 1967 by Karplus and Thier, the learning-cycle approach alternates hands-on exploration and applications and "minds-on" activities through interactions with the teacher, other students, and texts. Over the years numerous studies have supported the effectiveness of the learning cycle, particularly when all three phases of the cycle are utilized, and exploration precedes the introduction of concepts and terminology.

Rodger W. Bybee's 1997 5-E model is a learning-cycle modification: Engage, Explore, Explain, Elaborate, and Evaluate. The Launch, Explore, Summarize (LES) model is a condensed version of the 5-E model. Aaron D. Isabelle (2007) has described applying the "storyline approach" to LES to incorporate conceptual change.

Using questions, objects, or visuals the teacher elicits the students' prior knowledge and discusses the concept addressed in a story. The teacher then reads a story from the history of science, discusses the factual and fictional aspects of the story, and connects the ideas in the story with the original discussion.

Studies have repeatedly found that discussion is an important science learning tool for even the youngest students. Effective "talking science" can include practice using scientific terms in sentences, discussing intuitive theories, reading different types of science writing, and translating between scientific and colloquial questions and statements.

Finally, the guidelines set forth in *Science for All Americans* include:

- Teaching should include the history of science and societal and multicultural perspectives.
- Inquiry should lead to a satisfying conclusion.
- Curiosity and creativity should be fostered.
- Questioning should be encouraged and dogma avoided.
- The aesthetics of scientific phenomena should be emphasized.
- Local resources should be utilized.
- "Teaching should take its time."

Consistent with this last point is a recommendation from researchers and reformers that students should study in great depth the core explanatory ideas in science rather than quickly traversing many different ideas, which permits only shallow understanding.

APPROPRIATE ASSESSMENT

Research has shown that large-scale standardized tests alone are not a valid method for assessing scientific understanding. Generally these tests measure knowledge of discrete pieces of information rather than structured knowledge of science. However ongoing, appropriately designed assessment is an important component of science teaching and learning. Performance-based or alternative assessments may include:

- Performing a task or experiment
- Describing an exploration or the solution to a problem
- An essay
- A portfolio
- Student-teacher discussions
- Worksheets
- Journals

Formative assessment is used by teachers to adapt instruction and by students to improve learning. Formative assessment involves a three-step feedback process:

- Setting a learning goal
- Assessing the gap between the goal and the student's understanding
- Using feedback to eliminate the gap.

For example, a teacher may learn from a series of questions that students have not understood a concept and decide to modify a subsequent lesson to reinforce that concept. Likewise, students may modify their own work after comparing it to the teacher's example.

Achievements to be assessed include:

- Inquiry skills
- Knowledge and understanding of facts, concepts, principles, laws, and theories
- Understanding of the nature and functions of science
- Scientific reasoning abilities
- Using science to make decisions and develop opinions on issues
- The ability to communicate clearly about science.

The Lawrence Hall of Science's Science Education for Public Understanding Program (SEPUP), an issue-based 6-12 curriculum, works with the University of California's Berkeley Evaluation and Assessment (BEAR) Center. The SEPUP/BEAR system scores students on five concepts and abilities:

- Designing and conducting investigations
- Identifying objective scientific evidence and evaluating various solutions to a problem on the basis of evidence
- Understanding concepts and their problem-solving applications
- Communicating scientific information, including explaining methodologies, presenting results, and justifying conclusions
- Group interactions including collaborating on tasks and contributing ideas.

CHALLENGES TO EFFECTIVE INSTRUCTION

Research has consistently identified teacher proficiency as a major challenge in science education. Most K-8 teachers have little background in science and little training in teaching science. Schools often struggle just to teach basic literacy and math skills, and the science curriculum may

be nonexistent. Many teachers tell researchers that the major impediments to their science teaching are their own lack of knowledge combined with inadequate facilities, supplies, and preparation time. Furthermore, children arrive at school with very different experiences and attitudes toward science. Recognizing and addressing these differences poses a special challenge to teachers.

The inquiry-based approach, which requires teachers to guide student experimentation and discussion while incorporating specific learning goals, is a major paradigm shift for many teachers. In addition preparation for government-mandated high-stakes standardized testing and the demand that teachers strictly adhere to applicable science standards are often incompatible with student-centered, hands-on science instruction.

Finally, most science curricula and textbooks provide neither continuity for students nor guidance for teachers. Project 2061's analysis of science textbooks found them to be of almost uniformly poor quality, superficially covering a large number of topics with little attention to concepts. Although researchers agree that the science curriculum is far too broad, there is little agreement about which topics to emphasize and which to eliminate.

RESEARCH GROUNDED CURRICULUM PROJECTS

Concept-Oriented Reading Instruction (CORI) is a research program that integrates science inquiry and reading using the following support strategies to motivate students:

- Student autonomy
- Competence
- Learning goals
- Real-world interactions.

Elementary students are introduced to a complex domain such as ecology or the solar system. After several weeks they select a specific topic within the domain and choose related books to read. They receive help in finding and using resources and communicating what they have learned. Students also participate in related activities such as field trips, collecting, and experimentation. In a study of third and fifth graders in three schools, CORI students, as compared with students in the traditional science program,

- Reported greater interest in reading science
- Exhibited better reading comprehension of science texts
- Scored higher on standardized tests.

Several innovative curricula connect students with other students and with professional scientists. In the Global Learning and Observations to Benefit the Environment (GLOBE) project K-12 students worldwide study earth sciences in partnership with scientists. GLOBE has been shown to improve math, science, and geography skills, and students and teachers report increased interest in and awareness of environmental issues and satisfaction at having contributed to scientific research.

The Web-based Integrated Science Environment (WISE), developed by Marcia Linn and her colleagues, uses browser-based inquiry activities that enable middle and high school students to critique evidence, compare scientific arguments, and design solutions to scientific problems. WISE projects are interdisciplinary scientific issues and include hands-on data collection, online modeling, and design activities, as well as peer interaction and collaboration. The Center for Learning Technologies in Urban Schools (LeTUS) has developed very influential curriculum projects. The center is a collaboration of researchers at the University of Michigan and Northwestern University with Detroit and Chicago public schools. The center has developed inquiry-based instruction that has been shown to promote growth in conceptual understanding and reasoning. Students engage in projects around “driving questions,” core explanatory questions about interesting topics that motivate inquiry. The North Dakota State University World Wide Web Instructional Committee (WWWIC), an interdisciplinary research team, has developed multi-user, interactive virtual environments (IVEs) for teaching high-school science. In “Geology Explorer” students examine an alien planet and conduct geologic tests. In “Virtual Cell” students enter a simulated cell and perform biological experiments. A decade of research has shown that IVEs improve student achievement and problem-solving skills.

LEARNING AND TEACHING WRITING

Writing is a very demanding and complex task. Even a seemingly simple text, such as *Cat in the Hat*, can require considerable effort and expertise. It took Dr. Seuss well over a year to write the book, and he noted that “every word is a struggle every sentence like a pang of birth.”

Writing is a goal directed and self-sustained activity requiring the skillful management of the writing environment; the constraints imposed by the writing topic; the intentions of the writer(s), and the processes, knowledge, and skills involved in composing (Zimmerman & Reisemberg, 1997). It entails much more than this, however, as writing is a social activity involving either an implicit or explicit dialogue between writer(s) and reader(s). Writing is further shaped by the community of the writer. For example, written discourse differs considerably amongst a community of friends sharing ideas via email and texts written by biologists (Nystrand, 2006). Moreover, writing competence in one social community does not ensure competence in another. For instance, a good technical writer may not be a good novelist. What and how people write is also influenced by the cultural, societal, institutional, political, and historical background in which they are situated (Schultz & Fecho, 2000). To illustrate, students’ concepts about writing are shaped, at least in part, by institutional decisions about pedagogy and curriculum. If a school’s writing program places a heavy emphasis on correct form, students’ revising efforts will most likely involve editing. A different approach to revising is likely, though, if form is deemphasized and meaning and process are stressed.

WRITING THEORIES AND MODELS

Given its complexity, it is not surprising that there is currently no model or theory of writing that fully or adequately captures it. One conceptual approach to studying writing focuses mostly on the individual writer and concentrates on understanding the cognitive and the motivational processes involved in composing (Graham, 2006). This cognitive or cognitive/motivational approach is exemplified in an influential model of writing developed by Hayes (1996). In his model, he takes into account, at least in part, the interaction between the task

environment for writing and the internal capabilities of the writer. The task environment includes both a social component (e.g., the audience, other texts read while writing, and collaborators) as well as a physical component (e.g., text read so far and the writing medium, such as a word processor).

Internal factors include four main elements. First, cognitive processes: text interpretation, reflection, and text production. These processes allow the writer to form an internal representation of the writing task that can be acted upon; devise a plan to reach one or more writing goals; draw conclusions about the audience and possible writing content; use cues from the writing plan or text produced so far to retrieve semantic information that is then turned into written sentences; and evaluate plans and text and modify them as needed. Second, motivation, which includes the goals, predispositions, beliefs, and attitudes that influence the writing process. Third, long-term memory—knowledge of the writing topic and audience as well as linguistic and genre knowledge, including task schemas that specify how to carry out particular writing tasks. Fourth, working memory, which serves as an interface between cognitive processes, motivation, and memory, providing a space for holding information and ideas for writing as well as carrying out cognitive activities that require the writer’s conscious attention.

In the model proposed by Hayes (1996) only limited attention is devoted to the social nature of writing. The influence of writing community, culture, society, institution, politics, and history are mostly ignored. One or more of these factors are captured in sociocultural theories of writing. For example, Russell (1997) developed a theory for explaining how macro-level social and political forces influence micro-level writing actions and vice versa. A basic unit in this model is an activity system, which examines how actors (an individual, dyad, or collective—perceived in social terms and taking into account the history of their involvement in the activity system) use concrete tools (e.g., writing) to accomplish some action with some outcome (this is accomplished in a problem space where subjects use tools in an ongoing interaction with others to shape an object over time in a shared direction).

Russell’s theory also employs the concept of genre, “as typified ways of purposefully interacting in and among some activity system(s)” (p. 513). Genres are stabilized through regularized use of tools within and among individuals, creating a relatively predictable way of interacting with others, but they are only stabilized-for-now structures, as they are subject to change depending upon the context. Newcomers to an established activity system appropriate some of the routinized tools used by others (e.g., a particular structure for writing), but interactions between and among individuals and activity systems can change typified ways of acting

Primary grade students mastering basic writing skills. © PHOTOCRETE, 2008. USED UNDER LICENSE FROM SHUTTERSTOCK.COM.

(i.e., genres), as they may be modified or abandoned in response to changing conditions. Activity theory provides a method for describing and analyzing activity systems for writing and how they interact with macro-level activity systems involving academic discipline, culture, institution, society, and so forth.

To illustrate activity theory in action an example is given below of how political, institutional, societal, community, cultural, and historical factors might influence what happens in a second-grade class focusing on story writing. In this particular instance, the teacher's decision to concentrate on story writing was shaped by the district curriculum guide and the state's high-stakes testing program (story writing was emphasized in both) as well as the teacher's and her students' interest in story telling. The way in which story writing was introduced and taught was influenced by the teachers' beliefs about how to teach (which was previously influenced by her teacher preparation program, her own teachers as a child, and the culture of the school). In providing story writing instruction, the teacher used the same general routinized approach that she had applied when teaching personal narratives and other types of writing. Students also continued to generate papers using the same general script they had been using since the

start of the school year: selecting a topic, briefly planning what to say, making a draft, sharing it with a peer, revising and editing it, and sharing part or all of it with the class and at home.

While this script for writing was followed by most students, some of them modified it by eliminating a step (e.g., planning) or adding ones (e.g., sharing plans with a peer). The last of these modifications had a ripple effect in the classroom, as almost all of the students started sharing their plans with a peer. To provide students with concrete examples of stories, the teacher read traditional stories to the children (stories taken from her own dominant culture). However, one child brought to class a book of stories from Africa. He asked the teacher if they could try writing stories like those in his book. This request changed the focus of story writing in the class, as the teacher encouraged students to write stories from cultures other than their own, and several of the students' parents were asked to share their favorite stories from their culture with the class.

WRITING DEVELOPMENT

Not surprisingly, these two basic approaches to conceptualizing writing have led to different views of writing

development. For example, Graham (2006) argued that four catalysts spur writing development. These involve changes in writer's strategic or self-regulatory behaviors (e.g., becoming more sophisticated in planning), motivation (e.g., heightened sense of efficacy about one's writing capabilities), knowledge (e.g., increased knowledge about the attributes and structures of different types of writing), and skills (e.g., automatization of handwriting and spelling and proficiency in sentence construction). These catalysts all reside within the individual, and this approach to development is consistent with cognitive/motivational theories of writing.

In contrast, Schultz and Fecho (2000) offer a different view of writing development—one that is consistent with sociocultural theories of writing. They argue that writing development reflects and contributes to the social, historical, political, and institutional contexts in which it occurs; varies across the school, home, and work contexts in which it is situated; is shaped by the curriculum and pedagogical decisions made by teachers and schools; tied to the social identity of the writer(s), and is greatly influenced by the social interactions surrounding writing.

These two approaches (and the theories underlying them) clearly privilege different aspects of writing and writing development. However, neither is complete, as cognitive/motivational views pay relatively little attention to context, and sociocultural views do not adequately address how individual factors shape writing development.

LEARNING GOALS AND TEACHING WRITING

The primary learning goals in schools during the primary grades are for students to master basic writing skills (such as handwriting, spelling, grammar, and sentence construction); begin to develop the strategic process needed to write effectively (e.g., planning, gathering and organizing information, monitoring, evaluating, revising, and so forth), acquire fundamental knowledge about writing (e.g., knowledge about the characteristics of good writing, needs of audiences, and so forth), learn to use electronic tools for composing (e.g., word processing and publishing tools), start to develop a life-long love for writing, and use writing for various purposes (e.g., communicate, inform, entertain, persuade, reflect, and so forth).

As students move into middle and high school, these same goals remain in play (although it is typically assumed that students have mastered some basic skills such as handwriting and spelling), with an emphasis on increasing students' competence as writers. Although students continue to write for a variety of purposes, using writing as a method for displaying subject-matter knowl-

edge and as a tool for learning about such content becomes more prevalent. In some content areas (e.g., history), discourse genres typically used by that academic profession may be emphasized. At the college level, instructors may continue to emphasize more general writing development (especially for weaker writers), but as students enter classes in their majors, it is expected that they will learn the discourse styles and genres of that academic domain.

While states, school districts, and most schools have relatively clear goals for what students are to learn, there is no consensus on how to teach writing. The most prominent approach to writing instruction in the United States is the process approach (this is the only research-grounded general approach to writing instruction that has been extensively studied). This method is based on both cognitive/motivational and sociocultural views of writing. It involves extended opportunities for writing; writing for real audiences; engaging in cycles of planning, translating, and reviewing; personal responsibility and ownership of writing projects; high levels of student interactions, creation of a supportive writing environment; self-reflection and evaluation; and personalized individual assistance and instruction. This approach may only be effective, however, with teachers who are committed to its use and are trained in how to implement it. In a review of 21 studies, Graham and Perin (2007) found that this approach had little to no impact when these conditions were not met.

One concern with the process approach is that there may not be enough emphasis on explicitly teaching skills and strategic processes. The available empirical evidence indicates that directly and systematically teaching sentence construction skills and strategies for planning, revising, and editing as well as summarizing information can have a positive impact on improving the quality of students' writing (Graham & Perin, 2007). There is also some evidence that embedding more systematic instruction within the context of the process approach has a value-added impact on students' writing.

Students' writing skills can also be enhanced by providing them with assistance that helps them carry out one or more writing processes. Effective forms of support include clear and reachable writing assignment goals; help from peer(s) to carry out some aspect of the writing process; activities that help students generate, organize, and evaluate possible ideas for writing; examples of good writing that serve as a model for students; and technological supports such as word processing (Graham & Perin, 2007).

At present, it is not clear how these forms of effective writing practice should be combined or what amount of each should be provided. It is important to note that the

identification of evidence-based practices in writing is far from complete. There are many practices in which there is at least some empirical evidence to support their effectiveness (this includes practices such as teaching vocabulary as a way to improve writing and having students assess their writing using a rubric). It is also certain that there are many scientifically untested practices used by teachers that will prove to be effective when evaluated by researchers. The study of exceptional teachers of writing provides one possible approach for identifying practices that merit such assessment.

There is one research-grounded treatment that has a strong impact on improving how well students write, especially struggling writers. This involves explicitly teaching students how to plan, revise, and edit their papers (teachers model how to use strategies and provide students with guided practice aimed at promoting effective and independent use). In 20 experimental studies reviewed by Graham and Perin (2007), such instruction improved the quality of students' writing in every single investigation. Particularly effective was a specific model for teaching writing strategies. The Self-Regulated Strategy Development model (see Harris, Graham, & Mason, 2006) not only involves modeling and guided practice, students are also taught the knowledge and skills needed to apply the strategies as well as procedures for regulating their use. Furthermore, this instruction is criterion- instead of time-based. This means that instruction continues for youngsters until they reach mastery, instead of providing a set number of instructional sessions.

ASSESSMENT AND EVALUATION OF WRITING

Many procedures used to assess and evaluate writing quality are drawn from cognitive theories of writing. A cognitive approach to writing supposes that text production is a finalized and complete activity, in which several complex cognitive processes are activated. Therefore, assessment and evaluation of writing quality relies on the final product. Past research has focused on two measures of writing quality: subjective and objective. Subjective (or qualitative) measures use raters to evaluate writing quality based on one or more scales, whereas objective (or quantitative) measures consist of countable indices of writing sub-components.

Holistic, analytic, and primary-trait scoring are the three main subjective methods of evaluating writing quality. Frequently used, holistic scoring reflects a rater's overall impression of the writing, compared to other writing samples in the group. Holistic scoring is norm-referenced; that is, it provides a single score that ranks students within a particular group. Some holistic scoring methods also are criterion-referenced, using pre-determined characteristics

of writing quality in the scoring process. Holistic scoring is the most economical method of scoring direct writing assignments (Scherer, 1985). One drawback to holistic scoring is that it does not provide instructional guidance for areas of concern within a writing sample.

Analytic scales and primary-trait scales address the need for assessment to inform instruction. Analytic scales are criterion-referenced and provide separate scores in pre-determined areas of good writing, such as organization or development of the composition. They are the most reliable of all direct scoring assessment procedures (Scherer, 1985), although they take longer to score. One specific analytic scale, 6 Traits (and its later version: 6 + 1 Traits) has been used extensively in elementary and secondary schools. The 6 + 1 traits involve ideation, organization, voice, vocabulary sentence structure, conventions, and publication. Although developed for assessment, 6 Traits has been used as a method for writing instruction (see Graham & Perin, 2007, for a meta-analysis on the use of rubrics as an instructional method) and curriculum alignment, despite a lack of empirical research supporting its use for these situations.

Similar to analytic scales, primary trait scales also are criterion referenced. However, they differ from analytic scales in that the scoring guide is developed based on the specific purpose of each writing assignment. They can be used to assess the primary goal of the writing assignment (e.g., coherence of an argument) or to reflect genre-specific requirements (e.g., plot development).

Although in widespread use in both teaching and research, subjective measures of writing quality require scorer judgment and may be unreliable if extensive training and scoring directions are not provided. Other factors increase the variability of human scorers, such as fatigue, mood, and motivation (Freedman & Calfee, 1983). Computer-based scoring can parallel human graders; however, some scholars object to the validity of automated essay scoring (e.g., Ericsson & Haswell, 2006).

Reflecting a more sociocultural theory of writing, portfolio assessment collects several writing samples across different writing purposes and genres to gain a broader view of a student's writing ability. A good model of portfolio assessment includes the final product along with the drafts and revisions, allowing teachers to evaluate progress from start to finish. Some researchers advocate that portfolio assessment encourages students to develop writing over multiple occasions, rather than just a single sitting. Others believe that portfolios encourage more collaboration with peers rather than being teacher-centered, and that they are more consistent with teaching pedagogy (Murphy, 1994). Some districts and states collect student writing portfolios and then assess the written compositions using holistic, analytic, or primary-trait scoring methods. One concern

with portfolio assessment is the time and cost to gather and evaluate each student's writing, whether in the classroom or in large-scale testing.

Objective measures of writing include the number of words written, percentage of correctly spelled words, or percentage of correct word sequences, among others. Objective measures are moderately correlated with subjective measures of writing quality (Espin, Shin, Deno, Skare, Robinson, & Benner, 2000); however, they often focus on one aspect of writing and serve as indirect measures of writing quality. Generally, these measures have been used in formative evaluation, allowing teachers to make changes to a student's instructional program based on frequent assessment.

Concerns over how to adequately assess and evaluate the quality of student writing have plagued the field for decades. The multiple purposes of writing, a lack of agreement on how to teach writing, and the increase of large-scale writing assessment have contributed to the debate. Any writing assessment method must meet standards of reliability and validity, while addressing legitimate needs for efficiency and a linkage between assessment and instruction.

LEARNING DISABILITIES

Children and adults classified as learning disabled (LD) are individuals of normal intelligence who suffer mental information processing difficulties that influence their academic performance. Several types are referred to as LD, reflecting a heterogeneous group of individuals with intrinsic disorders that are manifested by specific difficulties in the acquisition and use of listening, speaking, reading, writing, reasoning, or mathematical abilities (Hammill, 1990). These definitions assume that the learning difficulties of such individuals are as follows:

1. Not due to poor instruction, but to specific psychological processing problems (e.g., remembering the association between sounds and letters) deriving from a neurological, constitutional, and/or biological base;
2. Not due to inadequate opportunity to learn, general intelligence, or to significant physical or emotional disorders;
3. Not manifested in all aspects of learning but specific to an academic behavior, for example, deficits in reading, but not arithmetic.

In several LD studies, children and adults with LD are operationally defined as having general IQ scores above 85 and standardized reading and/or math scores below the 25th percentile. The incidence of children with LD is conservatively estimated to reflect 2% of the public

school population. LD is the largest category of children served in special education.

ASSESSMENT ISSUES

Problems of definition have severely affected the field of LD as a discipline because considerable latitude exists among psychologists in defining LD. This latitude is influenced by social/political trends as well as non-operational definitions of LD. The field is further exacerbated by the fact that the number of individuals classified with LD increased dramatically between 1985 and the early 2000s.

One impediment to advances in the field is unresolved issues related to discrepancy and another related to the importance of IQ. Traditionally, studies of children with LD have relied primarily on uncovering a significant discrepancy between achievement in a particular academic domain and general intellectual ability. The implicit assumption for using discrepancy scores is that individuals who experience reading, writing, and/or math difficulties, unaccompanied by a low IQ, are distinct in cognitive processing from slow or low achievers (e.g., Fletcher et al., 1992). This assumption is equivocal (e.g., Hoskyn & Swanson, 2000; Stuebing et al., 2002). Many studies have compared LD children with reading disabilities (RD, i.e., children with discrepancies between IQ and reading) with non-discrepancy defined poor readers (i.e., children whose IQ scores are in the same low range as their reading scores) and found that these groups are more similar in mental processing difficulties than different (Hoskyn & Swanson, 2000; Stuebing et al., 2002). As a result, some researchers have suggested dropping the requirement of average intelligence, in favor of a view by which children with reading problems are best conceptualized as existing at the extreme end of a continuum from poor to good readers (Stanovich & Siegel, 1994).

With the Individuals with Disabilities Education Improvement Act (IDEA, 2004), the United States federal government recognized potential problems with the IQ-discrepancy method by formally stating that the IQ-achievement discrepancy method was not necessary for LD diagnosis. To facilitate identifying children with LD, three criteria were added to the law:

States are not required to use a severe discrepancy between intellectual ability and achievement.

The procedure must include a process in which the children's response to scientifically based research interventions is considered in the assessment process.

States are permitted to use alternative research-based procedure to determine a specific learning disability.

Changes in the law were based on the assumption that IQ levels in children with low reading scores were irrelevant to a valid classification of LD. One alternative approach is referred to as response to instruction (RTI).

The goal of RTI is to monitor the intensity of instruction and make systematic changes in the instructional context as a function of a student's overt performance. This is done by considering various tiers of instructional intensity. As of 2008, RTI as an assessment approach for defining LD has a weak experimental base. There have been no controlled studies randomly assigning children seriously at risk for LD to assessment and/or delivery models (e.g., tiered instruction vs. special education (resource room placement) that have measured outcomes on key variables (e.g., overidentification, stability of classification, academic and cognitive growth in response to treatment). In addition, different states and school districts variously interpret how RTI should be implemented further undermining any uniformity between the science of instruction and assessment of children at risk for LD.

The validity of using discrepancy as a basis for defining LD, however, is not easily confirmed. Hoskyn and Swanson (2000) found in a synthesis of the literature that although children with RD and poor readers share some deficits in phonological processing and automaticity (naming speed), the RD group's performance was superior to poor readers on measures of syntactical knowledge, lexical knowledge, and spatial ability (also see Fuchs et al., 2000). Another finding was that cognitive differences between the two ability groups are more obvious in the earlier grades. Perhaps more important, a meta-analysis of the intervention literature (Swanson & Hoskyn, 1998) found that students with LD and low achievers differ in the magnitude of their responsiveness to treatment. Review of several intervention studies suggests that students who have low reading scores (25th percentile) but average IQ scores were less responsive to interventions than children whose reading and IQ scores were in the same low range (25th percentile) (also see Swanson & Hoskyn, 1998, pp. 300-301).

Typically, researchers who study the processing difficulties of children with LD do not use discrepancy criteria (Swanson, 1989). The majority of researchers rely on cut off scores on standardized measures above a certain criterion of general intelligence measures (e.g., standard score > 85) and cut-off scores below a certain criterion (e.g., standard score < 85) on primary academic domains (e.g., reading and mathematics).

SUBTYPES

Because of the heterogeneity of individuals classified as LD, several subtypes have been discussed in the literature. However, some subtypes have been considered invalid because (a) the particular subtypes do not respond differently to instructional programs when compared to other subtypes, and/or (b) the skills deficient in a particular subtype is not relevant to the academic areas important in the school context.

There are two subtypes, however, with extensive research that are relevant to the school context: reading disabilities and mathematical disabilities. These subtypes are defined by standardized (normed referenced) and reliable measures of intelligence and achievement. The most commonly used intelligence tests are from the Wechsler measures and common achievement tests that include measures of word recognition or identification (i.e., Wide Range Achievement Test, Woodcock Reading Mastery Test, Kaufman Test of Educational Achievement, Peabody Individual Test) and arithmetic calculation (all the aforementioned tests and the Key Math Diagnostic Test). In general, individuals with IQ scores equal to or above a Full Scale IQ score of 85 and reading subtest scores equal to below the 25th percentile and/or arithmetic subtest score equal to or below the 25th percentile constitute two high incidence disorders within LD: reading disabilities and math disabilities.

In terms of reading disabilities, Siegel (1989; 2003) argues that fundamental to evaluating reading disabilities is focus on word recognition measures because they capture more basic cognitive processes and responses than reading comprehension. Her research shows that difficulties in phonological processing are fundamental problems for children with reading disabilities, a problem that continues to adulthood. She also indicates that there is no evidence to suggest that development of decoding skills is a result of a specific instruction in grapheme-phoneme conversion rules. Her work and the work of others find that there are three processes critical in analysis of reading disabilities: those related to phonological processing (ability to segment sounds), syntactical processing, and working memory (combination of transient memory and long term memory).

In terms of math disabilities, Geary (1993, 2003) finds that children with arithmetic problems do not necessarily differ from academically normal peers in terms of the types of strategies used to solve simple arithmetic problems. Differences, however, are found in the percentage of retrieval and counting errors. Children with math disabilities have long-term memory representations of arithmetic facts that are not correct. He provides taxonomy of three general subtypes of mathematical disability: those related to procedural errors,

those related to semantic memory, and those with visual/spatial difficulties. He indicates that the ability to retrieve basic arithmetic facts from long-term memory is a defining feature of math disabilities.

HISTORY AND INSTRUCTIONAL TRENDS

The term *learning disabilities* was first introduced in a speech by Samuel Kirk delivered in 1963 at Chicago Conference on Children with Perceptual Handicaps. Clinical studies prior to 1963 showed that a group of children who suffered perceptual, memory, and attention difficulties related to their poor academic performance but who were not intellectually retarded, were not being adequately served in the educational context.

Regarding the history of LD as a field, Wiederholt (1974) indicated that its unique focus was on identifying and remediating specific psychological processing difficulties. Popular intervention approaches during the 1960s and 1970s focused on visual-motor, auditory sequencing, or visual perception training exercises. Several criticisms were directed at these particular interventions on methodological and theoretical grounds.

By the late 1970s, dissatisfaction was expressed with a processing orientation to remediation of learning disabilities and with the influence of federal regulations in the U.S. (Public Law 94-142) remediation programs focused on basic skills such as reading and mathematics. The focus on basic skills rather than psychological processes was called direct instruction. The mid 1980s witnessed a shift from the more remedial-academic approach of teaching to instruction that included both basic skills and cognitive strategies (ways to better learn new information and efficiently access information from long-term memory). Children with LD were viewed as experiencing difficulty in regulating their learning performance. An instructional emphasis was placed on teaching students to check, plan, monitor, test, revise, and evaluate their learning during their attempts to learn or solve problems.

The early 1990s witnessed a resurgence of direct instruction intervention studies, primarily influenced by reading research, which suggested that a primary focus of intervention should be directed to phonological skills. The rationale was that because a large majority of children with learning disabilities suffer problems in reading, some of these children's reading problems are exacerbated because of lack of systematic instruction in processes related to phonological awareness (the ability to hear and manipulate sounds in words and understand the sound structure of language). This view gave rise to several interventions which emphasized phonics instruction and intense individual one-to-one tutoring to

improve children's phonological awareness of word structures and sequences.

SCIENTIFICALLY BASED TREATMENTS

Some experimental research shows that children with LD can be assessed and significant gains can be made in academic performance as a function of treatment (see Vellutino et al., 2004). However, considerable evidence suggests that some children with normal intelligence when exposed to the best instructional condition fail to efficiently master skills in reading, mathematics, and/or writing (e.g., Fuchs & Fuchs, 1998; Torgesen, 2000). Some literature suggests that LD individuals are less responsive than generally poor readers to intervention (e.g., Swanson & Hoskyn, 1998) and these academic problems persist into adulthood (e.g., Ransby & Swanson, 2003). Further, these difficulties in academic mastery reflect fundamental deficits in processing, such as phonological processing and working memory (Swanson & Siegel, 2001).

Swanson, Hoskyn and Lee (1999) provided a comprehensive analysis of the experimental intervention literature on LD. Their synthesis of methodologically sound studies (those with well-defined control groups and clearly identified LD samples) found that positive outcomes in remediating academic behaviors (e.g., reading, writing, mathematics) were directly related to a combination of direct and strategy instructional models. These models included a graduated sequence of steps with multiple opportunities for overlearning the content and skills, cumulative review routines, mass practice, and teaching of all component skills to a level that shows mastery. The interventions involved (a) teaching a few concepts and strategies well rather than superficially, (b) teaching students to monitor their performance, (c) teaching students when and where to use the strategy in order to enhance generalization, (d) teaching strategies as an integrated part of an existing curriculum, and (e) providing teaching that includes a great deal of supervised student feedback and practice.

Swanson (2000) found that two critical instructional components underlie successful instructional interventions for children with LD. One component was explicit practice that includes activities related to distributed review and practice, repeated practice, sequenced reviews, daily feedback, and/or weekly reviews. The other component was advanced organizers, and these studies included activities (a) directing children to focus on specific material or information prior to instruction, (b) directing children about task concepts or events before beginning, and/or (c) the teacher stating objectives of instruction.

LEARNING IN INFORMAL SETTINGS

Educational research typically explores how and what students learn and tends not to examine where students learn. The assumption is people learn in school. With some notable and impressive exceptions (e.g., Resnick, 1987), the subject of setting for learning simply has not been of critical importance to educational researchers. However, it is the central question for researchers who study learning in informal settings.

School is a physical setting operating roughly from nine in the morning until three in the afternoon for thirteen years of childhood. It is the formal setting for learning. But what are informal learning settings? Any visitor to the Metropolitan Museum of Art or to the Vatican would be amused to hear them referred to as informal. Should three friends exploring a neighborhood creek on a Saturday afternoon be as participating in an informal learning setting, or should some notion of structure and intentionality be included in defining such settings?

By structure, researchers assume that the informal learning does not simply happen in some place and time other than school, but that such places have reasonable physical and temporal boundaries. There has to be some sense of a setting to informal learning settings. Thus, they can be a museum, a concert auditorium, a farm, even a baseball field, but probably they are not parks, the dinner table during an interesting discussion, or a toy store.

This distinction leads to the notion of intentionality. Not all museum visits have learning as a goal, and a visit to a toy store could possibly be primarily educational in nature. It depends in part on the purpose for the visit. Jackson (1968) writes about intentionality as being a key distinguishing feature of teaching, and the concept generalizes well here. Many settings can provide the opportunity for learning, but not all do, nor do all settings at all times. Thus, informal settings for learning may be defined here as those circumstances outside school in which learning is clearly at least one of the goals of the event.

An informal learning setting should be a setting bound by space and time, and its intended use should be educational during the activities under consideration, for example, a class trip to a natural history museum to learn about the First Nations people who lived in the area and that the class is studying in school. It could be a small group of students going to an art museum to look at Islamic art in relation to a special report that they are writing on geometry. Or it could be a high school cooperative vocational program in which students enhance applied mathematics skills.

Informal learning settings have structure and intentionality. But should the term also include individuals of school age who are learning school-related subject matter (perhaps broadly defined) on their own in informal settings, what Falk and Dierking call “free-choice learning” (Dierking & Falk, 2003; Falk, 2005)? This would then

Students learning about art at a museum. GETTY IMAGES.

include family outings to informal learning settings, and programs developed by institutions to teach children in various areas, but that are not directly related to schools themselves. Finally, there is the increasingly looming question of the Internet. At the Timeline of Art History section of the Web site maintained by the Metropolitan Museum of Art, one can spend weeks learning about cultures from all over the world and all through the history of humankind. Should the definition of informal learning settings include virtual locations as well as physical ones?

These possibilities have been presented for two purposes: first, to limit what will be discussed in the remainder of this entry; and second, and the more important part, to suggest the incredible variety, potential, and power of learning in informal settings. There is a spectrum of possible definitions of learning in informal settings. At what might be called the narrow end of the spectrum, the definition from the perspective of the individual might be: "I am at this place at this time to learn something that is related somehow to what I am learning in school." At the broad end, the perspective might be: "I am not in school and yet I am learning." Although the broader end is clearly the more intriguing one, the narrower end is of great concern to those who are interested in building strong and useful relationships between schools and cultural institutions (and other institutions), and this relationship is the focus here. It is strongly related (perhaps identical) to Eshach's 2007 notion of non-formal learning. Eshach differentiates formal learning (school-based), informal learning (everything individuals learn outside of school), and non-formal learning (learning in a planned situation or organization, but not in school).

LIMITED RESEARCH

Traditionally, school learning in informal settings has been characterized by the one-time school trip visit to the museum, zoo, local company, or performing arts venue. Often, preparatory activities and auxiliary materials accompany such visits. But research literature says little regarding the efficacy of such programs to produce what might be called school-based learning. Griffin (2004) reviewed the literature on such trips and finds that in terms of statistically significant gains on cognitive measures related to school subjects, the evidence is equivocal at best. Bowker (2002) looked at factors that influence learning in museums and again found that the literature does not speak with a single voice. There are some indications of generalizable findings, such as the need for students to have some time on their own in a school visit and the strong possibility that the increase in interest associated with museum visits pays off in subsequent classroom learning (Borun, Flexer, Casey, & Baum,

1983). But, in general, the conclusion one has to reach is that there simply is not a whole lot of literature demonstrating the efficacy of the single-trip museum visit in terms of the kinds of learning that are valued in schools.

Although perhaps a bit depressing, this finding is not particularly surprising. There are a number of natural constraints on finding such effects, including the difficulty of studying the phenomenon in a rigorous fashion, the limited time frame of the museum encounter, and the frequent lack of congruence between what the museum has to offer and what the students are learning in school. The question that is raised by the paucity of research documenting the efficacy of school/museum interactions is: Do museums actually contribute to the learning of school-related material? That is, is the research scarce because it is hard to produce, or is it scarce because there is no real learning?

REFRAMING THE QUESTION

Basically, the answer to that question is that it is the wrong question. It is the wrong question for researchers and evaluators to have asked, and to a degree, the wrong questions for museum educators to have tried to live up to. For too many years, those concerned with education in informal settings have tried to show that museums can lead to higher test scores of one form or another. But the logical linkage between what a museum has to offer and what is measured on school tests is tenuous, and the path from one to another is often tortuous. This is not meant as a critique of either cultural institutions or the institution of school testing; both have their place. It is simply a statement that it is hard to find one's way from one place to another. As an example of the nature of the problem, a federally funded, three-year project at the Isabella Stewart Gardner Museum found that students in the project used critical thinking skills more in looking at art than children not in the program but that there was no discernible effect on standardized test scores (National School Boards Association, 2007). And this was for an extensive program. When one considers the additional constraints of a one-time visit to a museum, complete with bus trips, packed lunches, lining up, getting coats off and back on again, the difficulty in finding statistically significant findings on test scores comes more into focus.

Fortunately, better questions are being posed in the early 2000s. Researchers have stopped looking at informal learning settings as adjuncts to schools and have begun looking at them for what they can offer and excel at. Schauble and her colleagues argue that researchers need to include issues such as the sparking and maintenance of motivation and personal development when considering the impact of museum visits (Schauble et al.,

1996). Hooper-Greenhill (2004) addresses this issue as well, arguing that researchers need to consider broader educational goals, which she calls generic learning outcomes, instead of more subject or unit-within-subject specific goals. Citing efforts by Great Britain's Economic and Social Research Council

Teaching and Learning Research Programme, she lists (among others) as possible goals:

- positive identities of students as learners
- knowledge and skill acquisition
- acquisition of values and dispositions of a learning society
- development of personal, community and societal concerns

One might reasonably ask if these are properly school-related learnings. Perhaps in a No Child Left Behind world, one might have difficulty in finding such statements in the masses of standards that define each state's desiderata for student growth. But the list cited in Hooper-Greenhill aligns quite nicely with New Zealand's "Key Competencies," the centerpiece of its national curriculum document (Ministry of Education, 2007):

- Thinking
- Using language, symbols, and texts
- Managing self
- Relating to others
- Participating and contributing

It is perfectly reasonable to wonder, at this point, if museum education researchers have such difficulty in documenting small and specific effects, why would one expect to find broader effects. The answer is that is what museums do, when they are working well. They engender broader considerations and ideas, cause people to reflect beyond the visit, and encourage people to think in ways that perhaps they had not before. Although it is entirely possible to visit a museum and not be intrigued by anything in the collection, Carr (2006) argues that the very existence of objects of value and veneration should engender questions in the visitor. The visitor may ask about who made the artifacts, why they are important, and why they are displayed in a museum. Visitors may wonder about what the display means to them personally and how the displayed objects related. When individuals start to ask such questions and seek answers to them, learning occurs in various ways. First, knowledge is gained from the content and context of the objects themselves. Second, there is skill development in learning how to find answers to questions. Third, individuals often place themselves in the context of the objects,

leading to an exploration of a sense of community and identity.

DOCUMENTING A REVISED PERSPECTIVE

If, indeed, one can argue successfully that the learning that occurs in museums is of this broader and more substantial kind, how might one go about documenting such learning? This is a serious challenge, but one worth taking up. And there have been several promising starts. Leinhardt and Crowley (2002) begin from the perspective that one should be open to capture the learning as it occurs in the informal learning setting as opposed to determining what that learning should be a priori and then seeing if one can find the preconceived learning. This is a remarkable insight and one that might be well extended to learning in schools as well. Their approach to finding that learning is to have museum visitors fitted with recording devices so that they can listen to their conversations with others as they go to a museum, visit it, and return home from their visit. Leinhardt and Crowley call their approach, "learning conversations." Although their approach is costly, time-consuming, and can only sample very few participants, their results are nonetheless impressive. It is clear from their research that individuals in informal learning settings engage in conversations during and following visits that reflect authentic engagement with museum artifacts. They argue convincingly that the scope and level of these conversations, in comparison to conversations prior to the experience, are the types of experiences that lead to meaningful learning.

Bamberger and Tal (2007) utilized multiple observations in looking at the effects of choice on student learning. They video taped museum visits, conducted semi-structured interviews, and used questionnaires (the authors refer to them as worksheets). The data were coded so as to allow for assessment of those activities known to be related to student learning: student questioning, linkage to prior knowledge, scaffolding. As with the Leinhardt and Crowley approach, the authors did not look for specific learnings, but for the evidence of learning in general.

Finally, Smith and Waszkielewicz (2007) found that individuals (adults in this case) in an art museum were more likely to rate themselves highly in terms of thinking about interpersonal, intrapersonal, and societal concerns and issues while in the middle of a museum visit than at the beginning or the end of the visit. Like the two studies mentioned above, these authors gathered information on visitors during the museum visit. Their approach, however, used a fairly standard questionnaire format that allowed for the gathering of a quite large sample and replication over two museums using the same approach.

The research on learning in informal settings may not yield exactly what one might anticipate or, at the outset, even hope for. But as is so often the case in research, the new horizons are more intriguing than the old ones. As researchers learn that informal learning settings may or may not provide much support for acquiring everyday school objectives (as important as they are), they learn that they may well support broader and deeper goals. Educators look for growth in personal development, the ability to analyze and critique, a sense of belonging to structures and communities larger than one's own immediate group; they hope to make ties to the past and make conscious hope for better futures. What they find will almost certainly be different from what they envision, but the trip should be an enjoyable and rewarding one.

LEARNING STYLES

Learning styles theory is based on the understanding that differences between individuals' processing capabilities lead to significantly different learning requirements. Learning style theorists argue that these capabilities are fairly fixed, and most of the proponents believe that, in order for individuals to be successful learners, instruction needs to be matched to the individuals' learning preferences. While there is intuitive appeal in the notion that designing instruction to meet individual learning styles leads to improved academic achievement, there is a dearth of evidence to indicate that this concept has any validity. In fact, rather than increasing success in the classroom, research indicates that attempts to match instruction to specific learning styles fails to lead to improvements in student learning. Further, by limiting rather than expanding the range of educational approaches provided to learners, the use of learning styles has the potential to increase, rather than alleviate, the difficulties students experience in their learning.

LEARNING STYLES DESCRIBED

According to Vicki Snider (1990; 1992), learning styles are an outgrowth of the process approaches of the 1960s and 1970s although the construct is meant to describe differences between learners rather than to identify disorders (e.g., visual or auditory preferences rather than a visual-processing disability). Learning styles based education is also considered to be a form of aptitude-treatment interaction. Aptitude-treatment interactions are meant to identify individuals' distinct characteristics (aptitudes) and match these with specific treatments (for example, instructional approaches) in order to produce statistically improved outcomes (in this case, significantly improved learning).

The learning styles construct also encompasses a range of models, including learning preferences (for example, global versus analytical or visual versus auditory learners), cognitive styles (e.g., field dependence versus field independence or reflective versus impulsive), and personality types (e.g., the Myers-Briggs types). This range of models makes it difficult to develop a consistent definition of learning styles. However, there are two traits that appear to be constant across most descriptions of learning styles. First, learning styles are generally seen as fixed; that is, individuals have certain aptitudes that result from their natural tendencies or predispositions. Second, by matching learners with particular attributes to complementary instructional approaches, it becomes possible to increase their ability to process information.

So, for example, in terms of natural predispositions, field dependent individuals are identified by the difficulty they experience differentiating a particular item, or figure, as distinct from a complex background, or the surrounding field. Field independent individuals, by contrast, can be identified by their ability to readily distinguish between the two. Continuing with this example, field dependent individuals are considered to be social learners who benefit from collaboration and extrinsic motivation, whereas field independent individuals are considered to be independent learners who are intrinsically motivated and work best on their own. The argument continues that, by designing learning opportunities that take into account these innate preferences, it should be possible to improve the learning of both types of students.

ACADEMIC USEFULNESS

According to Ronald Hyman and Barbara Rosoff, in order to be a useful addition to the field of education, there are certain criteria that the learning styles construct would need to meet. First, the concept of learning styles needs to be clearly defined, both to allow ready identification of particular types of learners and to ensure effective communication regarding how best to meet these various learners needs. Next, it is important that accurate and efficient assessment measures be created to enable the easy identification of these distinct learning styles. Finally, there would need to be specific instructional approaches that lead to improved academic achievement when matched to students with a particular learning style (and, following from this, that are ineffective when matched with students who demonstrate alternative learning styles). Unfortunately, despite decades of research, the field of learning styles based education has failed to make significant progress in any of these areas.

Inconsistency of Definitions. There are numerous learning style models (71 according to a major review by

Coffield and his colleagues), many of which differ in terms of the attributes their proponents identify as critical to individual differences. In fact, although there is some degree of overlap, the advocates of these various models focus on an extensive array of qualities that they believe to be central to improving academic achievement. For example, some models look at environmental (e.g., temperature and sound), emotional (e.g., motivation and persistence), sociological (e.g., working alone or with others), and physical traits (e.g., time of day and need for mobility). Others consider the dimensions of perception (concrete or abstract) and ordering (sequential or random). Yet others define learners on two independent dimensions, cognitive organization (holistic or analytic) and mental representation (verbal or imagery). Ultimately, the fact that there are so many different models with such disparate views of what constitutes learning styles makes it nearly impossible to develop a cohesive definition upon which the field can build.

Assessing Learning Styles. In terms of the effectiveness of learning styles assessments, there are two ways in which these measures are problematic. The first and more serious issue is that, without a unifying definition of learning styles, it is impossible to develop a cohesive means of evaluating the construct. In other words, given the fragmented nature of the field, it is unclear how valid any assessment measure could be. Despite this problem, assessment measures have been developed for a number of individual models. However, Steven Stahl notes that these are generally considered to have low reliabilities for standardized procedures; for example, when individuals complete a particular evaluation at two different points in time (test-retest), the results are very often inconsistent. There are two possible explanations for this difference; either individuals' learning styles change quite significantly over relatively short periods of time or the assessments themselves fail to measure what they are meant to measure. Either way, the disparity undermines confidence in these assessments.

The Usefulness of Learning Styles. Given the above critique, it is apparent that the concept of learning styles is problematic. In fact, from the late 1970s onward, a number of major literature reviews set out to evaluate the research conducted on learning styles (or its predecessor aptitude-treatment interactions). Each of these reviews independently reached the same conclusion: There is a striking lack of evidence indicating that the matching of learners with particular modes of instruction, whether based on self-reported or observed learning preferences, is an effective means of improving academic achievement.

For example, both Vicki Snider (1992) and Steven Stahl discuss numerous attempts to improve learners'

reading ability by matching students who demonstrate particular types of modality preferences with the corresponding form of reading instruction. In these studies, visual or global learners have been taught using either whole word or whole language methods and auditory or analytic learners have been taught using a decoding or phonics-based approach. Results indicated that, despite the attempts to match children to the instructional approach that best complements their learning styles, there was no effect on reading achievement. One reason may be that, rather than possessing a particular learning style, students have different instructional needs at different points in their development.

According to many literacy researchers, early or emergent readers have been shown to benefit from more holistic approaches that emphasize concepts of print, language experience, and phonemic awareness. Once students have established these concepts, a focus on word recognition through phonics or decoding instruction is appropriate. As students develop comfort with the alphabetic principle, another shift occurs, and students consolidate their understanding of letter-sound correspondences and begin to develop their reading fluency. Using the most popular model for reading styles to describe what is occurring during these stages, the same student could be classified as a global or visual learner at the emergent stage, an analytic or auditory learner as the focus shifts to word recognition, and finally a global or visual learner again as the individual starts to develop reading fluency. Rather than arguing that students respond to a single type of instruction, it becomes apparent that what constitutes appropriate instruction changes as learners' needs change.

MULTICULTURAL LEARNING STYLES

Another problem that arises with the learning styles construct involves its application to broad cultural classifications. Advocates of this argument propose that students from various ethnic and cultural groups learn in fundamentally different ways from one another and that the education gap that exists between more successful white students and their lower achieving peers from different cultures (e.g., African American, Hispanic, Native American) is the result of culturally incompatible teaching. However, Craig Frisby argues that this contention is based upon several flawed assumptions; these range from the notion discussed above that learning styles and learning styles assessments are valid and reliable to the view that the members of various cultures must be taught in unique ways in order to demonstrate academic success. For example, according to some theorists, students from certain cultures prefer one modality over another and learn best when instruction is matched to those prefer-

ences. That is, some students are said to favor a lecture format and prefer having their work laid out in a step-by-step manner (analytic or auditory learners), whereas others are said to learn better when they have the opportunity to derive information through graphics and their material is presented holistically (global or visual learners), and still others are said to need to reinforce what they are learning through physical approaches in order to be successful (kinesthetic or tactile learners).

However, it is likely that students learn best, not as the result of a dominant processing preference being matched to its corresponding instructional approach, but as a result of educators' designing instructional approaches that are appropriate for the learning requirements of a particular situation. So that even auditory learners will develop a deeper understanding of, say, certain scientific concepts when given the opportunity to see a demonstration of that concept, than when they simply hear about that concept through a lecture. Similarly, most visual learners will develop a richer appreciation of a musical score after hearing a recording of it than they would after reading a critique of it. Likewise, although only some learners are classified as kinesthetic learners, it seems unlikely that individuals with other learning styles preferences will become competent at tennis simply by watching other players play the game or by learning about the steps involved in a serve without actually practicing it. Using these examples, it seems reasonable to argue that the modality people prefer has more to do with the nature of a given task than it has to do with individuals from certain cultural backgrounds having a cluster of learning requirements that develop out of a set of predetermined learning preferences.

ALTERNATIVES TO LEARNING STYLES

If learning styles are not the key to improved academic achievement, then what is? There are several educational approaches that can assist all learners, but are especially effective for those learners who are experiencing difficulties in the classroom. First, Vicki Snider (1990) suggests that teachers incorporate instruction that makes use of multiple modalities. Multimodality instruction differs from modality matching in that it incorporates visual, auditory, and tactile processing rather than just relying on one of these elements; such instruction has been shown to be effective with a range of learners, including those who are struggling with a particular curriculum. Second, when students encounter difficulty with their learning, rather than simply re-presenting the information in the same manner, teachers should consider where breakdowns may be occurring and how alternative ways of presenting the information can help students better

develop their understanding of the material at hand (e.g., scaffolding, the presentation of additional examples, collaborative discussions).

Finally, instruction in cognitive strategies should be considered in concert with these other instructional methods. Barak Rosenshine defines cognitive strategies as approaches, such as question-generation and summarizing, which help students succeed with complex learning tasks, such as comprehension, problem solving, and writing. What is important about cognitive strategies is that, unlike learning styles, there is a substantial body of research to demonstrate that these approaches lead to greater academic achievement and that this achievement occurs with a range of learners across ages, gender, culture, and socioeconomic background. Perhaps more importantly, each of these three principles can be integrated into any learning environment without relying on the limitations of learning styles or learning styles based education.

LONGITUDINAL RESEARCH

Educational researchers and practitioners are often interested in questions about how individuals grow and develop over time. For example, how rapidly does a student's understanding of various mathematical concepts change during secondary school? (Ai, 2002). To effectively answer such questions, *longitudinal data* (Singer & Willett, 2003) must be collected in which the same information may be obtained from individuals at different times. For example, to study the development of mathematics achievement during secondary school, yearly mathematics achievement tests could be administered. Longitudinal data is contrasted with *cross-sectional data*, in which information is collected from individuals at one point in time (e.g., mathematics achievement tests of children of different ages at the same point in time). While cross-sectional data is easier to collect than longitudinal data, it cannot be used to accurately answer questions about change.

This entry provides an example of the use of longitudinal data to study change in mathematics achievement during secondary school. The research addresses the following questions:

1. How much does mathematics achievement change during secondary school?
2. In what ways do trajectories of mathematics achievement differ across students?
3. Does mathematics achievement development differ as a function of student race?

These questions are addressed by fitting a statistical model called the *multilevel model for change* to five years of mathematics achievement data collected as part of the *Longitudinal Study of American Youth* (LSAY), a national longitudinal study of U.S. secondary school students (Miller, Kimmel, Hoffer, & Nelson, 2000). LSAY data were collected from 5,945 students over 7 years, beginning in the fall of 1987 when the students were in either 7th or 10th grade. A primary focus of the LSAY was on measuring students' mathematics achievement over time, using items from the National Assessment of Educational Progress. Here, in the example, are analyses of mathematics achievement data from a sub-sample of 1,322 White and African American students between 7th grade and 11th grade, asking about the effects of race on changes in the mathematics achievement over time.

THE MULTILEVEL MODEL FOR CHANGE

When studying change over time, the first questions are about each person's individual change trajectory. For example, does a particular student's mathematics achievement

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

improve rapidly during secondary school? Does another student’s achievement increase less rapidly? Might yet another student’s achievement actually decrease over time? These questions are addressed with the *level-1 statistical model*, or individual growth model, which represents the change that, according to the hypothesis, each member of the population will experience during the time period under study.

To develop an understanding of the level-1 model, the left-hand panel of Figure 1 should be considered, in which the researchers have plotted the mathematics achievement (MATHACH) of one African American girl from the dataset against her grade, between 7th and 11th grade. For this girl, mathematics achievement improves steadily over time. This upward trend is summarized in the empirical growth record by superimposing a fitted ordinary least squares (OLS) “achievement on grade” linear regression line. Observations based on this plot suggest two important components of this level-1 statistical model. First, the model should capture systematic underlying change in mathematics achievement over time (represented by the fitted growth trajectory plotted in Figure 1). Second, the model must account for differences between observed values of mathematics achievement (represented by the datapoints plotted in Figure 1), and the predicted values from the fitted growth trajectory. These observations lead the researchers to hypothesize the following level-1 model:

$$Y_{ij} = [\pi_{0i} + \pi_{1i}(GRADE_{ij} - 7)] + \epsilon_{ij} \quad (1)$$

This model asserts that, in the population of students from which this sample was drawn, Y_{ij} , the observed value of *MATHACH* for student i at time j is constituted from two important parts. The first part in brackets in equation (1) describes the underlying true change for this student as a linear function of his (or her) grade in school ($GRADE_{ij}$). This trajectory is characterized by two individual growth parameters, π_{0i} and π_{1i} , which determine its shape for the i th student. The intercept, π_{0i} , represents student i ’s true mathematics achievement in 7th grade. (This interpretation applies because the researchers centered *GRADE* in the level-1 model by subtracting the constant “7” from it.) The slope, π_{1i} , represents the yearly rate of change of student i ’s true mathematics achievement. The second part of the level-1 model is a random error term (ϵ_{ij}), which accounts for the difference between individual i ’s true and observed value of *MATHACH*, on occasion j . This level-1 residual represents that part of student i ’s value of *MATHACH* at time j not predicted by grade level.

In specifying a level-1 model, it is implicitly assumed that all students’ true individual change trajectories have a common algebraic form, here represented by a straight line. But because all the students have their own value of the intercept and slope parameters, everyone does not necessarily follow exactly the same trajectory. Students’ true mathematics achievement levels in seventh grade may vary, as may their rates of true change in achievement. Therefore, we may study inter-individual differences in individual growth trajectories by studying inter-individual variation in individual growth parameters. These observations form the foundation of the *level-2 statistical model*.

At level-2 the “between-person” or inter-individual level questions are asked about predictors of change. Here, in the mathematics achievement example, at level-2 it was asked whether the average African American seventh grader has lower mathematics achievement than the average White seventh grader, and also whether rates of change in mathematics achievement differ as a function of race. These questions are addressed by modeling the relationship between inter-individual differences in the change trajectories (i.e., intercept and slope parameters) and student characteristics (here, race). To develop an intuition about the level-2 model, the middle panel of Figure 1 should be examined. It represents an exploratory analysis in which the researchers have plotted fitted OLS individual growth trajectories for a random subset of 10 White and 10 African American students (solid lines represent African American students and dashed lines represent White students). As noted for the single student in the left panel, mathematics achievement increases over time for most students. In addition, African American students seem to have generally lower mathematics achievement scores in seventh grade than do White students, and their rates of increase in achievement over time are not as large. But the substantial inter-individual heterogeneity in growth trajectories within groups should also be noted. Not all African American students have lower intercepts than do White students; many of them have higher mathematics achievement in seventh grade. Similarly, not all African American students have less steep slopes; some of them have very rapid increases in mathematics achievement over time. Furthermore, within both groups there are students whose mathematics achievement actually decreases over time.

The level-2 model must simultaneously account for both these general patterns (the between-group differences in intercepts and slopes) and inter-individual heterogeneity that remains within groups. This suggests that an appropriate level-2 model would have outcomes that are the level-1 individual growth parameters themselves (the π_{0i} and π_{1i} parameters from equation (1)). In addition, the level-2 model must specify the relationship between each individual growth parameter and predictor *AFAM* (0 = White, 1 = African American). Finally, the level-2 model must allow even individuals who share common predictor values to differ in their individual change trajectories, by permitting random variation in the individual growth parameters across students. These considerations lead to the following level-2 model:

$$\begin{aligned} \pi_{0i} &= \gamma_{00} + \gamma_{01} AFAM_i + \zeta_{0i} \\ \pi_{1i} &= \gamma_{10} + \gamma_{11} AFAM_i + \zeta_{1i} \end{aligned} \tag{2}$$

Equation (2) has two main components which simultaneously treat the intercept (π_{0i}) and the slope (π_{1i})

of a student’s growth trajectory as level-2 outcomes that are associated with predictor *AFAM*. The level-2 model contains four parameters known collectively as the fixed effects γ_{00} , γ_{01} , γ_{10} , and γ_{11} that capture systematic inter-individual differences in change trajectories. In equation (2), γ_{00} and γ_{10} are level-2 intercepts; γ_{01} and γ_{11} are level-2 slopes. γ_{00} represents the average true seventh grade mathematics achievement for White students in the population, while γ_{01} represents the hypothesized population difference in average true initial status between African American and White students. Similarly, γ_{10} represents the population average true annual rate of change in mathematics achievement for White students, while γ_{11} represents the hypothesized population difference in average true annual rate of change between African American and White students. The level-2 slopes, γ_{01} and γ_{11} , jointly capture the effects of *AFAM*. If γ_{01} and γ_{11} are non-zero, the average population trajectories in true mathematics achievement differ between the two racial groups; on the other hand, if γ_{01} and γ_{11} are both 0, then the trajectories do not differ by race. These two level-2 slope parameters therefore address the question: What is the difference in the average trajectory of true change in mathematics achievement between White students and African American students?

Results of fitting a multilevel model for change to data (n=1,322)

		Parameter	Estimate (s.e.)
Fixed Effects			
Initial status, π_{0i}	Intercept	γ_{00}	53.02*** (0.26)
	AFAM	γ_{01}	-5.93*** (0.80)
Rate of change, π_{1i}	Intercept	γ_{10}	2.87*** (0.08)
	AFAM	γ_{11}	-0.48* (0.23)
Variance Components			
Level-1:	Within-person, ϵ_{ij}	σ_{ϵ}^2	37.17*** (0.86)
Level-2:	In initial status, ζ_{0i}	σ_0^2	59.05*** (3.23)
	In rate of change, ζ_{1i}	σ_1^2	3.19*** (0.29)
	Covariance between ζ_{0i} and ζ_{1i}	σ_{01}	6.18*** (0.69)

~ p < .10; * p < .05; ** p < .01; *** p < .001

This model predicts mathematics achievement between grades 7 and 11 as a function of (GRADE-7) at level-1 and race (AFAM) at level-2.

Table 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

An important feature of both the level-1 and level-2 models is the presence of the residuals (ϵ_{ij} at level-1 and ζ_{0i} and ζ_{1i} at level-2). As is the case with most residuals, researchers are usually less interested in their specific values than in their variability. Level-1 residual variance, σ_{ϵ}^2 , summarizes the scatter of the level-1 residuals around each person's true change trajectory, in the population. The level-2 residual variances, σ_0^2 and σ_1^2 , summarize the population inter-individual variation in true individual intercept and slope around their averages that is left over after controlling for the effect of *AFAM*.

As a final question at level-2, the researchers consider a potential association between seventh grade mathematics achievement and change in achievement. For example, do students with higher seventh grade mathematics achievement also experience larger gains in achievement? The researchers permit this possibility by allowing the level-2 residuals to be correlated. Their population covariance, σ_{01} , summarizes the association between true seventh grade math achievement and true rate of change in achievement, controlling for race.

INTERPRETING THE FITTED MULTILEVEL MODEL FOR CHANGE

Estimates from the fitted multilevel model for change are presented in Table 1. Substituting the $\hat{\gamma}$'s from Table 1 into the hypothesized level-2 model in equation (2), the following fitted level-2 model is obtained:

$$\begin{aligned} \hat{\pi}_{0i} &= 53.02 - 5.93AFAM_i \\ \hat{\pi}_{1i} &= 2.87 - .48AFAM_i \end{aligned} \tag{3}$$

The first part of this fitted model describes the estimated effects of *AFAM* on true seventh grade mathematics achievement; the second part describes its estimated effects on the annual rate of true change in mathematics achievement. Beginning with the first part of the fitted model, it is estimated that true seventh grade mathematics achievement for the average White student is 53.02. For the average African American seventh grader, it is estimated that true seventh grade mathematics achievement is 5.93 points lower (47.09). In addition, the researchers reject (at the .001 level) the null hypotheses that γ_{00} and γ_{01} are 0 and conclude that the average White student had non-zero true mathematics achievement in seventh grade (hardly surprising) and that there is a statistically significant difference in the average true seventh grade mathematics achievement of White students compared with their African American peers.

In the second part of the fitted model, it is estimated that the annual rate of true change in mathematics achievement for the average White student is 2.87 points

per year. For the average African American student, it is estimated to be nearly half a point lower (at 2.39). In rejecting (at the .001 level) the null hypothesis on γ_{10} , it is concluded that the average White student experienced a statistically significant increase in true mathematics achievement over time. Because the researchers also reject (at the .05 level) the null hypothesis on γ_{11} , they conclude that differences between African American and White students in their annual rates of true change are also statistically significant. The estimated mathematics achievement for the average White student increased 11.48 points from 7th grade to 11th grade, while the increase for African American students was two points lower (9.56). African American students begin seventh grade with lower average mathematics achievement than their White counterparts, and the achievement gap increases over time.

Another way of interpreting the estimated fixed effects is to plot fitted trajectories for prototypical individuals. For this particular model, only two prototypes are possible: an African American student (*AFAM*=1) and a White student (*AFAM*=0). Substituting these predictor values into equation (3) yields the estimated seventh grade mathematics achievement and annual growth rates for each:

When *AFAM* = 0:

$$\begin{aligned} \hat{\pi}_{0i} &= 53.02 - 5.93(0) = 53.02 \\ \hat{\pi}_{1i} &= 2.87 - .48(0) = 2.87 \end{aligned}$$

When *AFAM*= 1:

$$\begin{aligned} \hat{\pi}_{0i} &= 53.02 - 5.93 = 47.09 \\ \hat{\pi}_{1i} &= 2.87 - .48(1) = 2.39 \end{aligned} \tag{4}$$

These estimates are then substituted into the level-1 model in equation (1) to obtain the fitted individual change trajectories:

When *AFAM* = 0:

$$\hat{Y}_{ij} = 53.02 + 2.87(GRADE_{ij} - 7)$$

When *AFAM* = 1:

$$\hat{Y}_{ij} = 47.09 + 2.39(GRADE_{ij} - 7) \tag{5}$$

These fitted trajectories are plotted in the right-hand panel of Figure 1, and reinforce the numeric conclusions articulated above. In comparison to White students, the average African American student has lower mathematics achievement in seventh grade and a slower rate of increase in mathematics achievement.

The estimated variance components assess the amount of outcome variability left after including the

predictor *AFAM*. The level-1 residual variance, ϵ_{ij} , summarizes the population variability in average student's outcome values around their own true change trajectory. Its estimate here is 37.17. Rejection of the associated null hypothesis test (at the .001 level) suggests the existence of additional within-person outcome variability that may be predictable in subsequent analyses by time-varying predictors other than time.

The level-2 variance components, σ_0^2 and σ_1^2 , summarize the variability in true seventh grade achievement and rate of true change remaining after controlling for *AFAM*. Tests associated with these variance components evaluate whether there is any remaining outcome variation that could potentially be explained by further predictors at level-2. For these data, the researchers reject both of these null hypotheses (at the .001 level), and conclude that additional level-2 predictors may help explain some of this residual variation. Finally, the level-2 covariance component, σ_{01} is considered. The researchers reject the null hypothesis on the covariance and conclude that the intercepts and slopes of the individual true change trajectories are indeed correlated in the population. Controlling for student race, on average, African American and White students who have higher true mathematics achievement in seventh grade also have greater rates of increase in true mathematics achievement between 7th and 11th grade.

The mathematics achievement example presented in this entry has many features that simplify analysis and interpretation. However, the multilevel model for change is a very flexible, powerful method for analyzing longitudinal data and may be used to address quite complex longitudinal research questions. Five of these possibilities may be considered here. First, although only one predictor has been included in the analysis, it is straightforward to examine the impact of additional substantive level-2 predictors. For example, in addition to the race variable studied here, it could also be asked whether girls and boys have different mathematics achievement trajectories or whether there is an impact of various instructional methods on the development of mathematics achievement. Second, while all students in the example were assessed on exactly five occasions (a balanced design), the model may also be fitted to longitudinal datasets containing individuals with varying numbers of measurement occasions (an unbalanced design). Third, here measures of mathematics achievement that were taken in the fall of every year were analyzed, but occasions of measurement need not be equally spaced and different participants can have different data collection schedules. Fourth, individual change can be represented not only as a linear function presented here, but also curvilinear and discon-

tinuous functions representing substantively interesting hypotheses of change in educational outcomes over time. Finally, in addition to time-invariant predictors of change, such as race and gender, the effects of predictors whose values change over time can also be estimated, such as type and level of mathematics course in which a student is enrolled each year. Readers wishing to learn more about using longitudinal data to analyze change over time should consult books devoted to the topic, including Diggle, Heagerty, Liang, and Zeger (2002); Fitzmaurice, Laird, and Ware (2004); Hedeker and Gibbons (2006); Raudenbush and Bryk (2002); Singer and Willett (2003); Snijders and Bosker (1999); Verbeke and Molenberghs (2000); Walls and Schafer (2006); and Weiss (2005).

M

MACCOBY, ELEANOR E(MMONS) 1917–

Eleanor Maccoby's work on gender development, on the impact of divorce on children and families and parent-child interactions, and on child rearing practices has greatly informed the field of human development. In 1970, with Miriam Zellner, Maccoby described the underlying psychological concepts fueling various Project Follow Through programs (a government funded educational reform similar to Head Start). Their work, which focused on facilitating at-risk students' academic and social development, continues to be at the forefront of research in educational psychology and school reform. Similarly, Maccoby's research on the biological underpinnings of gender identity (1974, with Carol Jacklin) continues to help inform educators about the within-group differences of male and female groups, as well as the rather limited between-group differences of children's behavior and socialization practices. In addition, Maccoby's gender segregation research highlights the adult controlled contextual aspects of educational environments that reinforce and further promote children's (particularly girls') preferences for same sex playmates and peer groups through adolescence.

Born in 1917, Eleanor Maccoby began her college career at Reed College in 1934 and later transferred and received her BS in psychology from the University of Washington in 1939. After working for the Department of Agriculture's Division of Program Surveys as a study director, Maccoby completed her MS in 1949 from the University of Michigan, as well as her PhD in experi-

mental psychology in 1950. While at Michigan she taught survey research methods and served as study director in the Survey Research Center (APA). Maccoby completed her dissertation in B.F. Skinner's lab; however, over time her theoretical interests shifted from behaviorism to learning theory, cognitive development, and interaction. Her early work with Robert Sears and Harry Levin at Harvard on parent-child interactions continues to be influential. At Harvard (1950–1958), Maccoby was an instructor and lecturer in the Department of Social Relations (APA). She joined the faculty of the Department of Psychology at Stanford University in 1958 and was awarded emerita status in 1987. Since that time Maccoby has continued her research and commentary on topics ranging from the lifespan development of gender differences and socialization processes to adaptive outcomes of divorce and the impact of media exposure on children and families, as well as out of the home childcare.

Maccoby's publications number well over 100, including her most cited co-authored book with Carol Jacklin, *Psychology of the Sex Differences* (1974). The work of *Sex Differences* was instrumental in summarizing extant literature on gender differences, encompassing more than 1,300 previous works. Also important is her work on the Stanford Longitudinal Study (1984, with Jacklin), which used a cross-sequential design to provide a comprehensive description of the development of same-sex play groups and group processes. Throughout Maccoby's career her research has focused on in-depth longitudinal analyses of human development, and it has offered great insight into the role that teachers can play in students' lives, as well as the impact parenting style on children's development.

Maccoby is the recipient of numerous distinguished and lifetime career awards and positions, including the American Psychological Association (APA), Division 7 Gordon Stanley Hall Award in 1982, the American Educational Research Association's Distinguished Contributions in Educational Research Award in 1984; the Society for Research in Child Development (SRCD's) Award for Distinguished Scientific Contributions to Child Development in 1987; the APA's Distinguished Scientific Contribution Award in 1988; and the American Psychological Foundation's Gold Medal Award for Lifetime Achievement in the Science of Psychology in 1996 (APA, 2007). In addition, she was the first female chair of the Department of Psychology at Stanford. As of 2007 she was a member of the National Academy of Sciences and had served as president of SRCD and the Consortium of Social Science Association (APA).

MAEHR, MARTIN L. 1932–

Martin L. Maehr was born in 1932 in Guthrie, Oklahoma. Maehr grew up in Perry, Oklahoma, where his father was a principal, and later a professor of educational psychology and administrator at Concordia College in Nebraska. Maehr married his wife Jane in 1959. He received his bachelor of arts and master of divinity

degrees from Concordia Seminary in St. Louis. He then went on to doctoral study in psychology and education at the University of Nebraska. Maehr's dissertation was titled, "The Effect of Food Deprivation on Binocular Conflict," and his advisor was Warren R. Baller.

Maehr first studied for the ministry, with the expectation of teaching at a liberal arts college. He planned to enter a graduate program in classics, studying Greek and Latin, but a college administrator who was a friend of his family advised him to study educational psychology, because the university was investing resources into that area and not into classics. Maehr later met Dr. Robert E. Stake, a psychometrician. Stake encouraged Maehr's interests in psychology, which led to his dissertation research and later to experimental research on social motivation and achievement in school settings. Maehr has stated that his dissertation work, combined with several courses in counseling and social psychology, ultimately led to his career studying motivation.

Maehr's first academic position as an assistant professor was at Concordia Senior College in Ft. Wayne, Indiana. After several years of teaching, Maehr received a postdoctoral research fellowship from the National Institute of Mental Health that allowed him to conduct research in social psychology at Syracuse University. This was a turning point in Maehr's career, and in 1967 he moved to the University of Illinois Urbana-Champaign, where he served as director and professor at the Institute for Child Behavior and Development, as professor of educational psychology, and as associate dean for graduate and international programs. In 1992 Maehr moved to the University of Michigan, where he became director of the combined program in education and psychology, and a professor of education and psychology.

Maehr has published widely in the field of achievement motivation. His early work in motivation examined a variety of topics, including self-concept, Atkinson's theory of achievement motivation, and the "Pygmalion" effect. In 1976 Maehr published an influential article in *Review of Educational Research* titled "Continuing motivation: An analysis of a seldom considered educational outcome." In that article Maehr argued that motivation to continue engaging in academic tasks is an important, yet undervalued outcome, that should be fostered in classrooms.

During his time at the University of Illinois, Maehr worked alongside a number of other motivation researchers, including John Nichols, Carol Ames, and Carol Dweck. The conversations and collaborations between and among these scholars ultimately led to the development of goal orientation theory, and Maehr was one of the major contributors to this extremely influential framework for the study of motivation. His work involved measurement development, the application of

goal theory to classroom and school reform, and the relation of goal orientation theory to both school leadership and school culture. Along with the late Carol Midgley and other collaborators at the University of Michigan, Maehr helped to develop the *Patterns of Adaptive Learning Survey* (PALS), which is one of the most widely used measures of achievement goals in the world. He also published several climate and leadership inventories with Larry Braskamp. Maehr also collaborated with other motivation researchers, including Avi Kaplan, Tim Urdan, Dennis McInerney, Leslie Fyans, and Eric M. Anderman.

At the University of Michigan, Maehr collaborated extensively with Midgley and the late Paul R. Pintrich. Maehr and Midgley worked together on several large-scale projects. One of the most notable involved work on motivation-based school reform in elementary and middle schools; Maehr and Midgley and their students worked with teachers, administrators, and parents in order to change the policies and practices of schools to become more aligned with the pursuit of mastery goals. That work resulted in the publication of a book, *Transforming School Cultures*, in 1996. Maehr worked with Pintrich on many projects, including the editing of several editions of the well-regarded *Advances in Motivation and Achievement* series as well as other volumes on academic motivation.

Maehr published extensively. In addition to the *Advances in Motivation* series, he wrote and edited numerous other books, and published over 100 peer-reviewed articles and book chapters. His research was funded by the National Institutes of Health, the U.S. Department of Education, National Science Foundation, and the Spencer Foundation. He is a fellow of the American Psychological Association and the American Psychological Society.

Maehr retired from his position at the University of Michigan in 2005. However, he remained extremely active as Emeritus Professor of Education and Psychology at Michigan, and as the co-principal investigator on a large-scale NSF-funded project examining the assessment of motivation, and a study funded by the Spencer Foundation examining Middle Eastern students in public schools in the United States.

MASTERY LEARNING

Few programs have been implemented as broadly or evaluated as thoroughly over the last four decades in education as those associated with mastery learning. Programs based on mastery learning principles operate today in nations throughout the world and at every level of education. When compared to traditionally taught classes, students in mastery learning classes consistently have been shown to learn better, reach higher levels of achievement, and develop greater confidence in their ability to learn and in themselves as learners (Guskey, 1997, 2001).

THE DEVELOPMENT OF MASTERY LEARNING

Although the basic tenets of mastery learning can be traced to such early educators as Comenius, Pestalozzi, and Herbart (Bloom, 1974), most modern applications stem from the writings of Benjamin S. Bloom of the University of Chicago. In the mid-1960s Bloom began a series of investigations on the variation that existed in student learning outcomes. He recognized that while

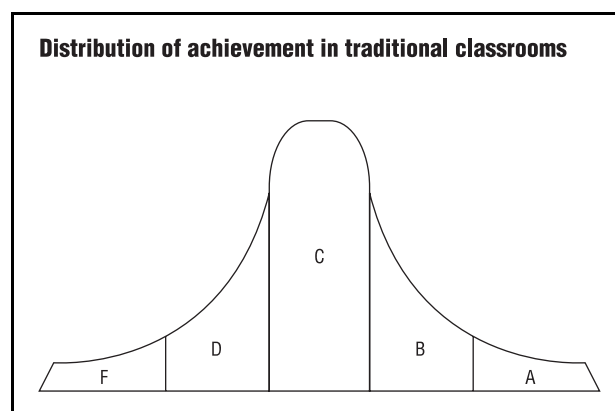

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

students vary widely in their learning rates, virtually all learn well when provided with the necessary time and appropriate learning conditions. If teachers could provide the time and more appropriate conditions, Bloom reasoned that nearly all students could reach a high level of learning.

To determine how this might be practically achieved, Bloom first considered how teaching and learning take place in typical group-based classrooms. He observed that most teachers begin by dividing the concepts and skills that they want students to learn into smaller learning units. Following instruction on the unit, teachers administer an assessment to determine how well students have learned those concepts and skills. Based on the assessment results, students are sorted, ranked, and assigned grades. The assessment signifies to students the end of the unit and the end of the time they need to spend working on the unit material. It also represents their one and only chance to demonstrate what they have learned.

When teaching and learning proceed in this manner, Bloom found that only a small number of students learns well and the pattern of student achievement was similar to the normal curve distribution shown in Figure 1.

Seeking a strategy that would produce better results, Bloom drew upon two sources of information. He first considered the ideal teaching and learning situation in which an excellent tutor is paired with each student. In other words, Bloom tried to determine what crucial elements in one-to-one tutoring could be transferred to group-based instructional settings. Second, he reviewed descriptions of the learning strategies of academically successful students in group-based learning environments that distinguish them from their less successful classmates.

Bloom saw value in organizing the concepts and skills to be learned into units and assessing students' learning at the end of each unit as useful instructional techniques. But the classroom assessments most teachers used seemed to do little more than show for whom their initial instruction was and was not appropriate. Bloom believed that a far better approach would be for teachers to use their classroom assessments as learning tools, and then to follow those assessments with a feedback and corrective procedure. In other words, instead of using assessments only as evaluation devices that mark the end of each unit, Bloom recommended using them as part of the instructional process to identify individual learning difficulties (feedback) and to prescribe remediation procedures (correctives).

This is precisely what takes place when an excellent tutor works with an individual student. If the student makes a mistake, the tutor first points out the error (feedback) and then follows up with further explanation and clarification (correctives) to ensure the student's

understanding. Similarly, academically successful students typically follow up the mistakes they make on quizzes and assessments. They ask the teacher about the items they missed, look up the answer in the textbook or other resources, or rework the problem or task so that they do not repeat those errors.

With this in mind, Bloom outlined an instructional strategy to make use of this feedback and corrective procedure, labeling it "Learning for Mastery" (Bloom, 1968), and later shortening it to simply "Mastery Learning" (Bloom, 1971a). With this strategy, teachers first organize the concepts and skills they want students to learn into learning units that typically involve about a week or two of instructional time. Following initial instruction on the unit, teachers administer a brief quiz or assessment based on the unit's learning goals. Instead of signifying the end of the unit, however, this assessment's purpose is to give students information, or "feedback," on their learning. To emphasize this new purpose Bloom suggested calling it a *formative assessment*, meaning "to inform or provide information" (see Scriven, 1967). A formative assessment identifies for students precisely what they have learned well to that point, and what they need to learn better (Bloom, Hastings, & Madaus, 1971).

Paired with each formative assessment are specific "corrective" activities for students to use in correcting their learning difficulties. Most teachers match these "correctives" to each item or set of prompts within the assessment so that students need work on only those concepts or skills not yet mastered. In other words, the correctives are "individualized." They may point out additional sources of information on a particular concept, such as page numbers in the textbook or workbook where the concept is discussed. They may identify alternative learning resources such as different textbooks, learning kits, alternative materials, CDs, videos, or Web-based instructional lessons. Or they may simply suggest sources of additional practice, such as study guides, computer exercises, independent or guided practice activities, or collaborative group activities.

With the feedback and corrective information gained from the formative assessment, each student has a detailed prescription of what more needs to be done to master the concepts or skills from the unit. This "just-in-time" correction prevents minor learning difficulties from accumulating and becoming major learning problems. It also gives teachers a practical means to vary and differentiate their instruction in order to better meet students' individual learning needs. As a result, many more students learn well, master the important learning goals in each unit, and gain the necessary prerequisites for success in subsequent units.

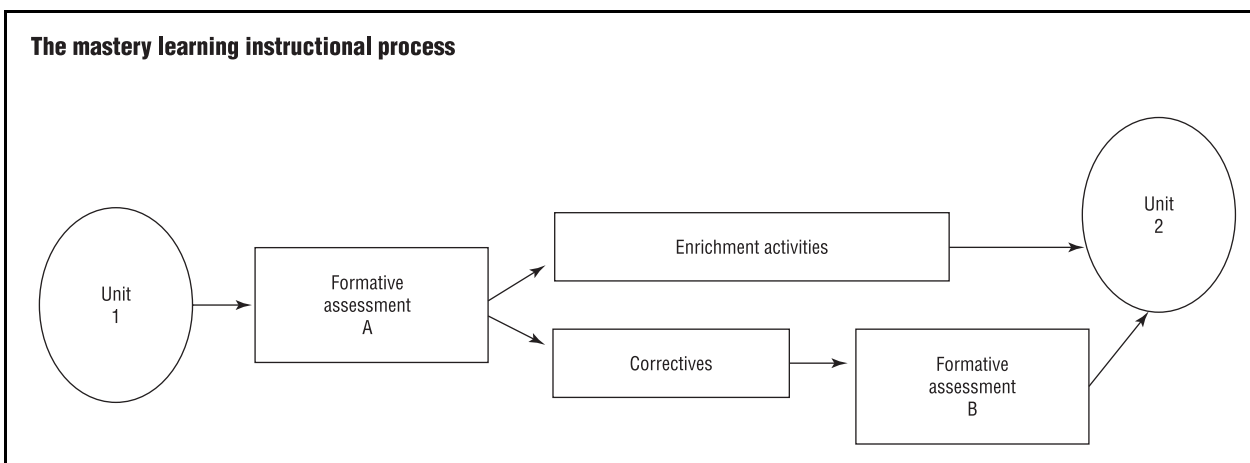

Figure 2 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

When students complete their corrective activities after a class period or two, Bloom recommended they take a second formative assessment. This second, “parallel” assessment covers the same concepts and skills as the first, but is composed of slightly different problems or questions, and serves two important purposes. First, it verifies whether or not the correctives were successful in helping students overcome their individual learning difficulties. Second, it offers students a second chance at success and, hence, has powerful motivational value.

Some students, of course, will perform well on the first assessment, demonstrating that they have mastered the unit concepts and skills. The teacher’s initial instruction was highly appropriate for these students and they have no need of corrective work. To ensure their continued learning progress, Bloom recommended that teachers provide these students with special “enrichment” or “extension” activities to broaden their learning experiences. Enrichment activities typically are self-selected by students and might involve special projects or reports, academic games, or a variety of complex, problem-solving tasks. Figure 2 illustrates this instructional sequence.

Bloom believed that through this process of formative classroom assessment, combined with the systematic correction of individual learning difficulties, all students could be provided with a more appropriate quality of instruction than is possible under more traditional approaches to teaching. As a result, nearly all might be expected to learn well and truly master the unit concepts or learning goals (Bloom, 1976; 1977). This, in turn, would drastically reduce the variation in students’ achievement levels, eliminate achievement gaps, and yield a distribution of achievement more like that shown in Figure 3.

Bloom emphasized, however, that reducing variation in students’ achievement does not imply making all

students the same. Even under these more favorable learning conditions, some students undoubtedly will learn more than others, especially those involved in enrichment activities. But by recognizing relevant, individual differences among students and then altering instruction to better meet their diverse learning needs, Bloom believed the variation among students in how well they learn specific concepts or master a set of articulated learning goals could eventually reach a “vanishing point” (Bloom, 1971b). In other words, *all* students would be helped to learn well the knowledge and skills prescribed in the curriculum.

MISINTERPRETATIONS OF MASTERY LEARNING

In some instances “mastery learning” has been confused with the concept of “mastery goals” used in motivation research (Ames, 1992; Dweck, 1986). Although theoretically related, these concepts are quite distinct. “Mastery learning” relates to a theory about learning and an accompanying set of instructional strategies, as described above. “Mastery goals,” on the other hand, concern a central distinction drawn by achievement goal theorists between striving to acquire skill and develop understanding (mastery goals), and striving to demonstrate superiority relative to others (performance or ability goals) (Butler, 2000). Mastery goals are typically associated with defining competence relative to task demands, attributing outcomes to effort, preferring challenging tasks, perceiving difficulty as an indication of the need for further learning, and responding to difficulty by seeking help and additional information. In contrast, performance or ability goals lead to defining competence relative to others, attributing outcomes to ability, interpreting difficulty as indicative of low ability, and refraining from

exposing inadequate ability by seeking help (Butler, 2007). Hence, while the criterion-referenced orientation of mastery learning clearly focuses on mastery goals, the concepts are quite different.

Another misinterpretation stems from some early attempts to apply mastery learning that were based on narrow and inaccurate understandings of Bloom's theory. These efforts focused only on low-level cognitive skills, attempted to break learning down into small segments, and insisted that students "master" each segment before being permitted to move on. Teachers were regarded in these programs as little more than managers of materials and record-keepers of student progress. Unfortunately, similar misinterpretations of mastery learning continue (e.g., Prawat, 1992; Satterly, 1981).

Nowhere in Bloom's writing, however, can this kind of narrowness and rigidity be found. In fact, Bloom emphasized quite the opposite. He considered thoughtful and reflective teachers vital to the successful implementation of mastery learning and continually stressed flexibility in its application. In his earliest description of the process Bloom wrote:

There are many alternative strategies for mastery learning. Each strategy must find some way of dealing with individual differences in learners through some means of relating the instruction to the needs and characteristics of the learners. . . . The nongraded school (Goodlad & Anderson, 1959) is one attempt to provide an organizational structure that permits and encourages mastery learning. (Bloom, 1968, pp. 7-8)

Bloom further emphasized his belief that instruction in mastery learning classrooms should focus on higher level learning goals, not simply basic skills. He noted:

I find great emphasis on problem solving, applications of principles, analytical skills, and creativity. Such higher mental processes are emphasized because this type of learning enables the individual to relate his or her learning to the many problems he or she encounters in day to day living. These abilities are stressed because they are retained and utilized long after the individual has forgotten the detailed specifics of the subject matter taught in the schools. These abilities are regarded as one set of essential characteristics needed to continue learning and to cope with a rapidly changing world. (Bloom, 1978, p. 578)

Modern research studies have shown mastery learning to be particularly effective when applied to instruction focusing on higher level learning goals such as problem solving, drawing inferences, deductive reasoning, and creative expression (Arredondo & Block, 1990; Blakemore, 1992; Clark, Guskey, & Benninga, 1983;

Kozlovsky, 1990; Mevarech, 1980, 1981, 1985; Mevarech, & Werner, 1985; Soled, 1987). When well implemented, the process helps teachers improve student learning in a broad range of learning goals from basic skills to highly complex cognitive processes.

RESEARCH RESULTS AND IMPLICATIONS

Despite the modest nature of the changes required to implement mastery learning, extensive research evidence gathered in Asia (Kim et al., 1969, 1970; Wu, 1994), Australia (Chan, 1981), Europe (Dyke, 1988; Langeheine, 1992; Mevarech, 1985, 1986; Postlethwaite & Haggarty, 1998; Reezigt & Weide, 1990, 1992; Yildiran, 2006), South America (Cabezon, 1984), and the United States (Anderson, 1994; Block, Eftim, & Burns, 1989; Guskey & Pigott, 1988; Walberg, 1984, 1988), shows the careful and systematic application of mastery learning principles can lead to significant improvements in student learning. Some researchers even suggest that the superiority of Japanese students in international comparisons of achievement in mathematics operations and problem solving may be due largely to the widespread use in Japan of instructional practices similar to mastery learning (Nakajima, 2006; Waddington, 1995).

Long-term investigations have yielded similarly impressive results. A study by Whiting, Van Burgh, and Render (1995), for example, representing 18 years of data gathered from more than 7,000 high school students showed mastery learning to have remarkably positive influence on students' test scores and grade point averages as well as their attitudes toward school and learning. Another field experiment conducted in elementary and middle school classrooms showed that the implementation of mastery learning led to significantly positive increases in students' academic achievement and their self-confidence (Anderson, Barrett, Huston, Lay, Myr, Sexton, & Watson, 1992). Even more impressive, a comprehensive, meta-analysis review of the research on mastery learning by Kulik, Kulik, & Bangert-Drowns (1990a) concluded:

We recently reviewed meta analyses in nearly 40 different areas of educational research (J. Kulik & Kulik, 1989). Few educational treatments of any sort were consistently associated with achievement effects as large as those produced by mastery learning. In evaluation after evaluation, mastery programs have produced impressive gains. (p. 292)

Research evidence also shows that the positive effects of mastery learning are not limited to cognitive or achievement outcomes. The process also yields improvements in students' confidence in learning situations, school attendance rates, engagement in class activities, attitudes toward learning, and a variety of other affective

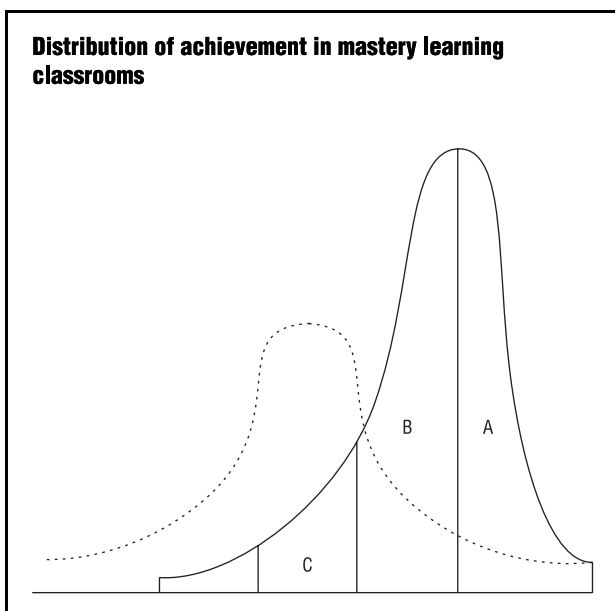

Figure 3 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

measures (Block & Burns, 1976; Block, Efthim, & Burns, 1989; Guskey & Pigott, 1988, Whiting & Render, 1987).

It should be noted that one review of the research on mastery learning, contrary to all others, indicated that the process had essentially no effect on student achievement (Slavin, 1987). This finding surprised not only scholars familiar with the vast research literature on mastery learning showing it to yield very positive results, but also large numbers of practitioners who had experienced its positive impact firsthand. A close inspection of this review shows, however, that it was conducted using techniques of questionable validity (Joyce, 1987; Hiebert, 1987), employed capricious selection criteria (Anderson & Burns, 1987; Kulik, Kulik, & Bangert-Drowns, 1990b), reported results in a biased manner (Bloom, 1987; Walberg, 1988), and drew conclusions not substantiated by the evidence presented (Guskey, 1987, 1988a). Most importantly, two much more extensive and methodologically sound reviews published since (Guskey & Pigott, 1988; Kulik, Kulik, & Bangert-Drowns, 1990a) have verified mastery learning's consistently positive impact on a broad range of student learning outcomes and, in one case (i.e., Kulik, Kulik, & Bangert-Drowns, 1990b), showed clearly the distorted nature of this earlier report.

Researchers in the 21st century generally recognize the value of the central elements of mastery learning and their importance in effective teaching at any level of education. Similar elements provide the foundation for

more recently developed instructional approaches including differentiated instruction (Tomilson, 2003) and understanding by design (Wiggins & McTighe, 2005). As a result, fewer studies focus on the mastery learning process, *per se*. Instead, researchers are looking for ways to enhance results further, adding additional elements to the mastery learning process that positively contribute to student learning in hopes of attaining even more impressive gains (Bloom, 1984a, 1984b, 1988; Walberg, 1990). Recent work on the integration of mastery learning with other innovative strategies appears especially promising (Arredondo & Block, 1990; Guskey, 1988b, 1990a, 1990b; 1997b; Motamedi & Sumrall, 2000).

Mastery learning will not solve all the complex problems facing educators. Nevertheless, careful attention to the elements of mastery learning allows educators at all levels to make great strides in their efforts to reduce the variation in student achievement, close achievement gaps, and help all children to learn excellently.

MATHEMATICS, LEARNING AND TEACHING

SEE *Learning and Teaching Mathematics*.

MCKEACHIE, WILBERT J(AMES) 1921–

The life of arguably one of the most influential educational psychologists began humbly in a one-room school house in White Lake, Michigan. With his father as the lone teacher, Wilbert (Bill) J. McKeachie (born August 24, 1921) began a journey of life-long learning that spanned nine decades. His life experiences include serving as a church minister, a mathematics teacher, a naval radar officer, president of multiple academic organizations, and a marriage to the same woman (Ginny) for 65 years.

After graduating from Michigan State Normal College (later Eastern Michigan University), he spent four months teaching mathematics and serving as a United Methodist minister in Trout Lake, a small town in Michigan's Upper Peninsula. His application for clergy deferment was denied, and in January 1943 he reported for naval training in San Francisco. From June 1943 until the end of World War II, he served as a radar officer on the USS *Guest*. Every destroyer in the *Guest's* fleet was hit, and eight of nine were sunk. Only the *Guest* survived.

Upon his return from war, McKeachie entered the doctoral program in psychology at the University of Michigan. He studied the then-emerging field of personality and social psychology, exploring issues of group formation and conformity, under Michigan's department chair Donald G. Marquis. When McKeachie received his degree, Marquis convinced him to forgo opportunities to join the faculty at other universities and instead stay at Michigan and coordinate the introductory psychology program. McKeachie joined the faculty at Michigan in 1948 and officially retired in 1992, although he continued his work as an emeritus professor into the early 2000s.

His honors and awards (over 30 citations) reflect the many spheres on which his career had an influence. Most

notable among them are the Thorndike Award for Outstanding Research from APA Division 15, APA's Centennial Award for Outstanding Contribution, American Psychological Foundation Gold Medal Award, and APA's Presidential Citation.

In addition to these awards, McKeachie led several academic organizations. He served as president of the American Psychological Association, the American Psychological Foundation, the American Association for Higher Education, and was founding president of the Educational, Instructional, and School Psychology Division of the International Association of Applied Psychology. McKeachie served on the editorial boards of 20 journals and on governing boards of 17 organizations in higher education, many times serving in multiple capacities. (For example, he served in 22 different leadership positions for the American Psychological Association alone.)

Picking the most significant research contributions of someone with more than 390 publications is difficult. Still, three can be highlighted here. His signature written work is arguably his internationally recognized book *Teaching Tips*, as of 2008 in its twelfth edition. This book started as mimeographed copies of pedagogical strategies that he distributed to his teaching assistants in 1951. The book appeared in several languages and was widely respected by university professors. With its wide-ranging content from test-writing to leading discussions to establishing good relations with university support staff it is the quintessential survival guide for new faculty.

Second, the modern-day freshman-experience course has roots in McKeachie's work. These courses, along with the spate of related books, can arguably be traced to McKeachie's course entitled "Learning to Learn," which he first offered at Michigan in 1971. Like most of his work, the course was ahead of its time. It was his attempt to bring what were, at the time, pioneering concepts of motivation and cognition to help college students become better learners. The result was a national trend of most universities offering such courses.

Third, McKeachie was instrumental in securing funding for the National Center for Research to Improve Post-Secondary Teaching and Learning, which was housed at Michigan for five years. The most fruitful product from the center's existence was the Motivated Strategies for Learning Questionnaire (MSLQ), a self-report instrument designed to assist college students in assessing their learning strategies and motivation. Its subscales include what became fundamental concepts in the field of educational psychology such as self-efficacy, critical thinking, and goal orientation. The MSLQ has been used in hundreds of universities, dozens of countries, and translated into several languages.

Lest McKeachie be known as a one-sided academic with no interests or skills outside his career, it is worth noting that he was an amateur music composer, producing a range of works that include his high school fight song in 1939, a civil rights song in the 1960s, and several pieces that were sung by his own First Baptist Church of Ann Arbor. He also had a talent for pitching fastpitch softball. He pitched games in seven decades (from the 1930s to the 1990s), accumulating more than 900 victories. These and other accomplishments, too numerous to mention, demonstrate how his original love of learning that began in White Lake, Michigan, spread across his whole life.

MEMORY

Alan Baddeley's 1999 book describes the case of Clive Wearing, a talented musician who in 1985 fell ill with a viral infection that resulted in encephalitis which caused

extensive brain damage. Wearing could no longer remember what happened more than a few minutes before. He continued to believe that he had just regained consciousness and kept a diary in which he constantly recorded that belief. Wearing could, however, still play music. Thus, some kind of memory remained intact. His case demonstrates the importance of memory.

In 1968 Atkinson and Shiffrin developed a model consisting of three different kinds of memory: sensory, short term, and long term (Atkinson & Shiffrin, 1968). Sensory memory is very brief, lasting about 1/3 of a second (Sperling, 1960). Short-term memory is temporary memory storage. It has limited capacity and duration. Long-term memory is a more enduring memory.

SHORT TERM MEMORY AND WORKING MEMORY

Miller described the capacity of short-term memory (STM) storage as 7 ± 2 bits of information (Miller, 1956). Contents in short-term memory last about 20 to 30 seconds unless an individual rehearses or elaborates on the material. There are two kinds of rehearsal: maintenance rehearsal and elaborative rehearsal. Maintenance rehearsal involves the repetition of the contents of STM; elaborative rehearsal involves a deeper form of rehearsal by which people connect the to-be-remembered information to what they already know. One way to reduce the demands on working memory involves chunking information, or grouping bits of information. For example, when trying to remember the phone number 555-1212, it is easier to remember two chunks ("555" and "1212") rather than the seven individual numbers. Information is lost from short-term memory through decay and interference. Decay occurs when information is not used, and it simply fades from memory. Interference occurs when something else gets in the way of recall.

The probability of recalling information presented in a list is influenced by the position of the information in the list, a phenomenon known as the *serial position effect*. Recency effects indicate that items from the end of a list will be recalled, and primacy effects indicate that words at the beginning of a list will be recalled. Recognizing the limits of short-term memory, teachers can keep their instructions brief and provide opportunities for rehearsal.

A MODEL OF WORKING MEMORY

Working memory is a term used to describe a limited, though active, memory system. It differs from short-term memory in that it includes manipulation functions as well as storage. Baddeley proposed that working memory has a number of subsystems that are coordinated by a *central executive* (Baddeley, 1990). The first of these subsystems is the *phonological loop system*, which processes

speech or auditory information. It consists of a passive phonological store and an articulatory rehearsal process.

The Phonological Loop System. The phonological loop processes verbal information. Evidence for it includes the phonological similarity effect, the unattended speech effect and the word length effect. People make more errors if the words they are asked to recall are similar in sound to one another (Baddeley, 1993). When individuals are asked to perform a verbal task (e.g., reading) with speech in the background, performance is impaired, a phenomenon known as the *unattended speech effect*. Verbal information that is presented auditorially is processed automatically. A third source of evidence in support of the phonological loop is found in the *word length effect*. There is a link between memory span and the length of words to be recalled.

The Visuospatial Sketchpad. A second subsystem in Baddeley's model is the *visuospatial sketchpad*, which is used for processing visual or spatial material or both. The results of a 1968 study by Brooks showed that when an individual engages in a visuospatial task such as pointing while performing a visual imagery task, the same processing capacity is being used. If the form of the task (verbal or visual) and that of the response (verbal or visual) are the same, performance is impaired.

The Executive System. The central executive system of working memory controls the phonological loop and the visuospatial sketchpad. It is an attentional control system with limited capacity (Baddeley, 1993). Daneman and Carpenter's 1980 study explored the relationship between working memory and reading comprehension by asking individuals to read passages that contained inconsistencies due to the presence of words with more than one meaning. Individuals with low working memory spans were able to come to the correct conclusion only 25% of the time. Individuals with high working memory spans were able to keep the initial information in working memory until they encountered the information that clarifies the passage. Additional research suggests that the functioning of the central executive system is the key difference between good and poor comprehenders (Oakhill, 1982, 1984; Oakhill, Yuill, & Parkin, 1986).

MEMORY DIFFICULTIES OF CHILDREN WITH SPECIAL NEEDS

When instructions are complicated or lengthy, there is a risk that students will not remember them. If students fail to follow instructions, it may be that the instructions exceeded their working memory's capacity for processing information. Interruptions are frequent in elementary school classes and it seems reasonable to assume that

the constant interruption can produce interference effects. Working memory is involved in such tasks as reading comprehension, writing, problem solving, and mathematics (Swanson & Siegel, 2001).

Individuals with a large working memory span utilize cognitive resources more efficiently while reading, and as a result have more resources for storage while comprehending the text (Swanson & Siegel, 2001). Students must also retrieve information from long-term memory to include in their writing. Maintaining ideas and choosing among them while actually producing text can make heavy demands on memory capacity. Some learners have difficulty writing because of limited working memory capacity.

Students with learning disabilities frequently have deficits in working memory (Swanson & Siegel, 2001). In particular, they have difficulty with reading comprehension because of deficits in the phonological loop. Such difficulties are problematic on tasks that require a learner to retain information in mind for a short period while also carrying out further activities. This skill is very important in reading tasks in which information that is coming in must be stored temporarily while other information is being processed (Swanson & Alexander, 1997). Difficulties with working memory can also interfere with writing, because efforts to record ideas may interfere with maintenance rehearsal in working memory.

Students and teachers can use a variety of strategies to reduce the demands on working memory. Children often count on their fingers, thus giving themselves a visible record of their cognitive activity rather than relying on memory. Other strategies for supporting working memory include presenting information in multiple modalities, allowing students to record their ideas before writing, or using speech-to-text software to reduce the burden on working memory. Using an external representation can reduce the demands on working memory.

LONG TERM MEMORY

Researchers have described several types of long-term memory. The Atkinson and Shiffrin model was based on the duration of memory. Processing was divided among sensory, short-term, and long-term memory. This model was very useful, but it does not provide a complete description of how memory works.

There are several ways to distinguish between various kinds of long-term memories. One important distinction is between episodic and semantic memory (Tulving, 1972). Episodic memory is memory of events and typically includes sensory information (things seen, heard, or smelled, and so on). Such memories often have heightened emotional content (happy, sad, fearful). These memories are embedded in a specific context—a specific

time and place. In contrast, semantic memory is memory of verbal information or declarative knowledge—that is, knowledge about facts. For example, knowing one's address is an example of declarative knowledge. It is separate from sensory information and not tied to particular experiences. Combining episodic and semantic memories makes information more memorable and retrievable.

Semantic memory is memory for meaning and is thought to be organized like a network. In 1969 Collins and Quillian proposed the earliest network model of semantic memory. In this model, semantic networks are made up of a network of related propositions, the smallest units of meaning that can be verified as true or false. A proposition involves linking two concepts by a relationship. Connections between ideas also vary in strength and frequency of use. These factors are more important than the actual categorical structures.

A second distinction in types of memory is between declarative and procedural memory. Declarative memory is like semantic memory. For example, a person might have declarative memories about the structure of a bicycle. In contrast, procedural memory is memory about how to do something. In the example given above, Clive Wearing had retained procedural memory of how to play music.

IMAGES

Responding to a question about an image takes about the same amount of time as responding to a picture (Kosslyn, 1976). In one study, participants were asked to form a mental image of a cat. They were then asked questions such as, "Does the cat have a head?" and "Does the cat have claws?" Responses to the latter question took longer, as participants appeared to scan the image.

Image information is thought to be stored in piecemeal fashion in long-term memory. Images are created by activating the overall or global shape of the image; elaborations are then added to create a complete image (Kosslyn, 1980, 1983). More detailed images take longer to retrieve. Images are thought to be stored in a non-image format that specifies a *recipe* for constructing the image. As with the processing of language, processing images takes time.

SCHEMAS AND SCRIPTS

Semantic memory is organized in complex networks. Complex understanding of a domain will result in a dense network of interconnected propositions about that domain. *Schemas* refer to organized sets of propositions about a topic (Bartlett, 1932). Learners' available schemas influence how they interact with the environment.

The learner's schemas may be altered as a result of interacting with the environment.

A schema that describes the typical sequence of events in a situation is called a *script*, or *event schema*. For example, when people go to a restaurant, they usually expect actions to unfold in a particular way. Another type of script is a story grammar that can help students to understand and remember stories (Gagné, Yekovich, & Yekovich, 1993).

LEVELS OF PROCESSING

In 1972 Craik and Lockhart proposed an alternative theory of memory. It suggested that memory differences are not so much a function of duration as of depth of processing (Craik & Lockhart, 1972). They showed that students who attended to meaning performed significantly better than those who attended to surface features of the words. Craik and Lockhart argued that the differences in performance reflected differences in depth of processing.

Craik and Lockhart's concept of levels of processing helped shift the emphasis in the study of memory from storage to processing. The Atkinson and Shiffrin model defined memory systems in terms of the storage/duration of memories and described very short stores (sensory and short-term memory) and very long-term stores (long-term memory). The levels of processing theory focuses on the likelihood of retrieval as a function of how effortful and meaningful the initial encoding was.

ENCODING: ORGANIZATION, PRACTICE, AND ELABORATION

Encoding is the taking in of information. The probability that information will be retrieved or remembered depends on the quality of encoding. Key processes in good encoding are organization, practice, and elaboration. It is easier to learn organized material than it is to learn disorganized material.

Practice helps develop good memory. Material that is used more often is remembered more easily. However, there are different ways of practicing. Distributed practice is much more effective than massed practice. Distributed practice is done over a period of time, with varying intervals between rehearsals of the information. Remembering involves using the cues available to assist remembering but also involves generating cues that help remembering. Distributed practice allows students to practice both of these skills. Massed practice, in contrast, involves engaging in extensive practice at one time, such as studying all night before an exam. This can be somewhat effective for an immediate task but is unlikely to lead to long-term recall of information.

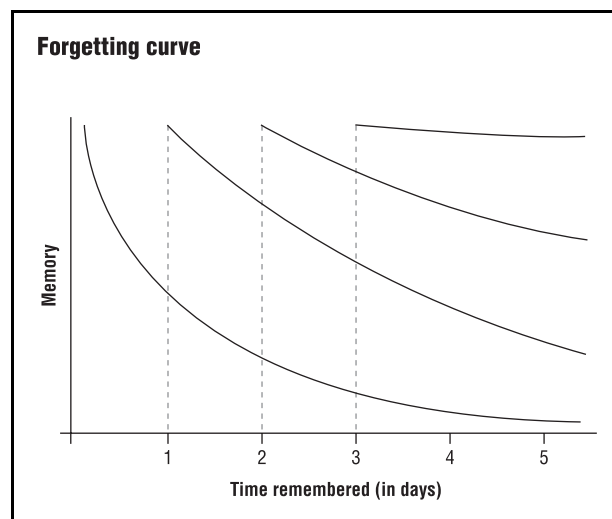

ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

Elaboration also helps in encoding and retrieval. It involves connecting new information with prior knowledge or to images or other enhancements of the information to be learned. Images in particular are powerful aids to memory and are frequently used to elaborate on information.

IMAGERY AND VISUAL LEARNING STRATEGIES

Dual-coding theory (Paivio, 1986) explains why images are helpful in remembering. According to this theory, images and words are represented differently, as *imagens* and *logogens*. When the two forms of representations are linked, the memory for the information is stronger. Baddeley's findings on the separate working memory systems for visual and verbal information also support the importance of presenting and learning information in both visual and verbal forms (Baddeley, 1999). Visual strategies such as concept maps and graphic organizers integrate verbal, visual, and spatial information to enhance encoding and retrieval.

RETRIEVAL AND FORGETTING

Remembering can occur through either recognition memory or recall. Recognition memory responds to cues. Responding to multiple-choice tests can require recognition memory because the cues provided by the options from which one may choose will provide some assistance to memory. When information is recalled, one must generate information without cues. Responding to an essay question, for example, requires that one generate and organize the content.

Retrieval occurs within a semantic network because activation is spread from one node to another. Related ideas are triggered. The specific linkages will vary from one person to another. Because of the structure of a network, retrieval can involve reconstructing the links between propositions and ideas.

Forgetting occurs when there is interference or decay. When material is encoded in an organized manner, more cues are encoded, thus making retrieval easier. Also, information that is used more frequently is easier to recall. Material that is not encoded in an organized way and not used often is more likely to be forgotten. This is so because in a propositional network model of memory, retrieval occurs through a process of spreading activation. When one node in a network is triggered, related nodes are also triggered as activation spreads along the links to them. When these links are used often, less activation is needed to generate the connecting node. If the nodes are highly interconnected with many links, forgetting is less likely, but retrieval may take longer. In a curious irony, the more people know, the longer it may take them to verify that they know it.

Forgetting occurs when information is not used. If students have not practiced solving geometry problems for a year, they are likely to have forgotten the steps in doing so. Forgetting also occurs because of interference.

BRAIN PROCESSES AND MEMORY

A number of structures in the medial temporal lobes of the brain are important for memory. They include the amygdala, the hippocampus, and the rhinal cortex that underlies the amygdala and hippocampus. The hippocampus plays a key role in the storage of new memories (Gazzaniga & Heatherton, 2003). The hippocampus and surrounding rhinal cortex are the most important areas for the consolidation of memory (Eichenbaum, 2002; Gazzaniga & Heatherton, 2003). The frontal lobes are also considered important for memory; although people who experience damage to the frontal lobes do not suffer dramatic memory loss, they may have difficulty remembering the order of events. Brain-imaging studies show that when people try to remember a list of words, the frontal lobes light up (Buckner, Kelly, & Petersen, 1999). The frontal lobes are more active when a task requires deeper encoding.

Angela M. O'Donnell

MENTAL RETARDATION

With the advent of the Binet test in the early 20th century, professionals were provided with a way of quantifying intelligence and defining the condition subsequently known as mental retardation. Later, the American Association on Mental Retardation (AAMR) assumed a leading role in defining mental retardation for professional audiences. The AAMR definition was updated frequently in response to changes in the way that mental retardation was conceptualized by those in the field. As of the early 2000s AAMR definition states: "Mental retardation is a disability characterized by significant limitations both in intellectual functioning and in adaptive behavior as expressed in conceptual, social, and practical adaptive skills. This disability originates before age 18" (American Association on Mental Retardation, 2002). Examiners use standardized tests to assess intellectual and adaptive behavior functioning. As a part of the standardization process for these measures, normative groups are used to determine age based deviation scores that have a mean of 100 and, usually, a standard deviation of 15 points. Significant limitations are present when these scores are more than two standard deviations below the mean (i.e., a score of 70-75 allowing for the standard error of measurement for the specific assessment instrument used).

The AAMR definitions have typically been incorporated into current versions of other diagnostic systems. For example, the language of the 1992 AAMR definition is clearly evident in the *Diagnostic and Statistical Manual of Mental Disorders IV TR* (APA, 2000). In contrast, state educational agencies vary considerably in which definition of mental retardation is used to establish eligibility guidelines. A survey of state agencies conducted by Denning, Chamberlain, and Polloway (2000) revealed that the 1983 AAMR definition of mental retardation was being used in 86 percent of the states in either verbatim or an adapted version and that only 7.9 percent of the states had incorporated the 1992 AAMR definition in an adapted or verbatim format. Moreover, 5.9 percent of the states used alternative definitions. The reasons for these differences in definition were not readily apparent from the published report.

In the early 2000s, the term *mental retardation* is rapidly falling into disfavor among professionals, families, and self-advocates. There is considerable pressure to change the term to something that is perceived as less stigmatizing, such as intellectual disability. Intellectual disability is the term that is currently used in many other English speaking countries, and, perhaps for that reason, this term was chosen by the American Association on Mental Retardation as a replacement in its organization name. The American Association on Intellectual and

Developmental Disabilities is in concert with other prominent organizations such as the International Association for the Scientific Study of Intellectual Disabilities and the President's Committee for People with Intellectual Disabilities. Although there is increasing momentum for widespread change in terminology, the term mental retardation remains imbedded in public policy. For example, a diagnosis of mental retardation is typically required to establish eligibility for state and federal disability programs such as the Individuals with Disabilities Education Improvement Act of 2004, Social Security Disability Insurance, and the Medicaid Home and Community Based Waiver. Schalock, Luckasson, and Shogren have argued that "intellectual disability covers the same population of individuals who were diagnosed previously with mental retardation in number, kind, level, type and duration of the disability, and the need of people with this disability for individualized services and supports" (2007, p. 120). Although it is relatively easy for a professional association to adopt a change in terminology, as of 2007 it is expected to be some time before other associations and governmental entities would follow suit no matter how much the change is needed.

ASSESSMENT

Contemporary definitions of mental retardation require assessment of general intellectual functioning and adaptive behavior to determine a diagnosis. General intellectual functioning is measured by an individually administered, standardized intelligence test. Measures appropriate for school age children include the Wechsler Preschool and Primary Scale of Intelligence (3rd ed.), the Differential Ability Scales-II, the Wechsler Intelligence Scale for Children (4th ed.), Kaufman Assessment Battery for Children-II, and Stanford-Binet (5th ed.). Test selection is based on the chronological age of the child and the child's general level of functioning as well as the test's ability to clearly differentiate among children who perform at the lower end of a particular test. Given the likelihood that a child with mental retardation may also have sensory impairment or physical disability or be nonverbal, assessments have to be highly individualized and require the use of specialized measures designed for these populations. For example, intelligence tests appropriate for nonverbal or hearing impaired students are the Test of Nonverbal Intelligence-3 and the Leiter International Performance Scale (Rev.). In general, intellectual assessments for children with mental retardation require an examiner with considerable skill and experience in the assessment of children with special needs (Sattler & Hoge, 2006).

Adaptive behavior is typically assessed by informant report given the need for information about typical behavior that would go beyond that observed in a formal testing situation. Informants can include parents, teachers, or some

other adult with considerable knowledge of the child's daily functioning. Measures of adaptive behavior assess personal and social competence in meeting common life demands as determined by the child's chronological age as well as the child's cultural background. Examples of areas assessed by these measures include: communication and language skills, social and interpersonal skills, gross and fine motor skills, and degree of independence in daily living skills. There are several well standardized measures available as of 2007, including the Adaptive Behavior Assessment System-II, Scales of Independent Behavior (Rev.) and the Vineland Adaptive Behavior Scales-II. These instruments vary in their coverage, but all assess skills and abilities consistent with the conceptual, social, and practical dimensions of adaptive behavior in the 2002 AAMR definition as well as the specific adaptive skill areas delineated in the DSM-IV TR (2000) (i.e. communication, self-care, home living, social skills, community use, self-direction, health and safety, functional academics, leisure skills, and work skills for adults only).

CHARACTERISTICS OF MENTAL RETARDATION

Children with mental retardation are typically identified because they do not keep pace with developmental expectations in cognitive, language, social, and motor functioning. Typically, significant developmental delays in early childhood are predictive of poor academic functioning in childhood, as compared with same-age peers. Considerable study has been directed toward identifying the cognitive difficulties associated with mental retardation. Most of this work was conducted using experimental designs based on the deficit model of mental retardation. That is, comparisons were made between children with mental retardation and their same chronological age peers. Using this framework, nearly every cognitive process studied revealed dramatic differences between the two groups. The areas of study included attention, working memory, perceptual organizational skills, verbal problem solving, visual-spatial problem solving, vocabulary, language and abstract reasoning, among others. Subsequent studies have adopted a developmental perspective, in which the functioning of children with mental retardation is compared with typically developing children of comparable developmental level. Although some differences remain, it is clear that children with mental retardation generally follow the same developmental pathways as their typically developing peers but at a slower rate and do not ultimately attain as high a level.

Similarly, slower progress in attaining independence in meeting common life demands, or adaptive behavior, characterize children with mental retardation. It is a matter of some debate as to whether the observed deficits

in adaptive behavior are a function of deficits in intellectual functioning. In fact, empirical studies indicate a high degree of correlation between measures of intelligence and adaptive behavior suggesting that they are not entirely independent entities. Moreover, some authors suggest that there are unique aspects of adaptive functioning that are not tapped by existing measures. These attributes include social intelligence, social competence, vulnerability, gullibility, and credulity. Greenspan (1999) argues that deficits in these areas contribute to the victimization of children with mental retardation as well as social and economic exploitation.

INDIVIDUAL DIFFERENCES AMONG CHILDREN WITH MENTAL RETARDATION

Throughout the 20th century, people realized that there are demonstrable and clinically relevant differences among people with mental retardation. Traditionally this differentiation was based on level of functioning. The terms mild, moderate, severe, and profound are in the early 2000s used in DSM IV TR to designate levels of mental retardation that correspond to standard deviation units below the mean. Mild mental retardation is defined as between two and three standard deviations below the mean, moderate mental retardation is between three and four and so on. These categories have endured because there are clear differences among the levels in both cognitive performance and adaptive functioning. A similar subgroup classification system, using different terminology (i.e., educable, trainable, severe/profound), is still employed by some state education departments (Denning et al., 2000).

In 1992 the American Association on Mental Retardation published a revision of its classification manual that represented a paradigm shift for the field. In this system, reliance on a deficit oriented approach (i.e., mild, moderate, severe, and profound) was supplanted by a supports-based approach to describing the individual needs of persons with mental retardation. By so doing the severity level descriptions were abandoned and a diagnosis of mental retardation was based solely on IQ and adaptive functioning scores below 70 to 75. The new classification system required description of the degree of support needed to maximize a person's performance across a variety of functioning areas. Support was defined in terms of intensity and duration and categorized as intermittent, limited, extensive, and pervasive. Support needs were designated for each area of functioning recognizing that an individual may require more intensive supports in some areas as contrasted with others. Accordingly, a person might require extensive supports in academic activities and intermittent support in self-care

activities. Ultimately this information could inform intervention planning and enhance the person's overall functioning level. The AAMR (later AAIDD) published a Supports Intensity Scale for use with adults, with a children's version of the Supports Intensity Scale expected to follow.

A emphasis within the field as of 2007 is to focus on etiology in describing subgroups of children with mental retardation. For example, research aimed at defining the behavioral characteristics, or phenotypes, of various genetic disorders is moving ahead at an accelerated rate. Although a great deal of research has been focused on Fragile x, Angelman, Prader-Willi, Smith Magenis, and Williams syndromes, much was also published on Down syndrome. Studies of specific genetic disorders have yielded information regarding cognition, language and communication, visual-spatial skills, social development, and maladaptive behavior that has implications for educational professionals (Fidler, Hodapp, & Dykens, 2002).

INTERVENTIONS AND INSTRUCTIONAL PROCEDURES IN THE EARLY 2000S

Beginning with the Education for All Handicapped Children Act in 1975, the Individualized Education Plan has been the blueprint for educational services provided to children with mental retardation. This act established that all children, regardless of ability, were guaranteed a free and appropriate public education in the United States. The early 21st century version of this landmark legislation is known as the Individuals with Disabilities Education Improvement Act of 2004. A guiding principle of this legislation is that services should be provided in the least restrictive environment. That is, children with disabilities should receive educational services with their typically developing peers to the greatest degree possible. The goal for students with disabilities is inclusion within the general education setting. Inclusion means more than physical presence in the classroom or other education setting. Various practices are used to facilitate inclusion such as cooperative learning and peer tutoring experiences as well as instructional tools or strategies that enhance the salience of the academic content. Generally speaking, children with needs for extensive or pervasive supports spend the majority of their day in self-contained educational settings while children with less intense support needs may spend the majority of their day in a general education class with special education teacher services.

Early 2000s legislation such as the No Child Left Behind Act has reinforced the view that children with disabilities, including mental retardation, should graduate from public schools with basic or fundamental knowledge in mathematics, literacy, science and technology,

practical skills sufficient to be self-supporting upon graduation, and problem-solving skills that foster lifelong learning. The success with which students with mental retardation achieve these skills varies considerably. For those who experience the greatest challenge with the general curriculum, efforts have yielded a functional curriculum that provides critical skills needed to participate in daily routines. These skills include independent living skills, communication, social skills, academic skills, and transition and community living skills. Support within the general education curriculum for children with mild mental retardation can be achieved in several different ways such as the use of accommodations that provide equal access to learning, curriculum modifications based on the child's current level of academic mastery, and adaptations of instructional methods to facilitate completion of assigned tasks.

Instructional procedures vary according to the needs of individual children. In general, children with mental retardation require explicit instruction if they are to succeed in school. Research has focused on a variety of methods to maximize instructional outcome and to promote generalization to real world settings. Examples of these methods include encouraging choice-making and self determination to enhance motivation to learn, teaching self-monitoring skills to encourage independence in completing academic tasks, and embedding instruction within activities to promote stimulus generalization and student motivation while distributing instructional trials over longer periods of time.

ISSUES RELATED TO ASSESSMENT AND INSTRUCTION

Children with mental retardation are likely also to have other deficits, such as cerebral palsy, seizure disorders, and sensory impairment (such as hearing and/or visual problems). In general, children with severe or profound mental retardation are at greater risk for these associated conditions as compared with children with mild or moderate mental retardation. Children with mental retardation are also at increased risk for health conditions that may affect their attendance at school as well as their participation in school activities. Finally, children with mental retardation are also at greater risk for speech problems. These difficulties can include difficulty with articulation as well as voice problems such as abnormal pitch or voice intensity.

Psychiatric diagnoses are more common among children with mental retardation as compared with their typically functioning peers. Epidemiological studies suggest that the risk may be as much as four times greater. For example, a study of 10,000 children aged 5 to 15 years in Great Britain revealed that 39 percent of children with mental retardation met DSM-IV and ICD-10

criteria for at least one psychiatric disorder as compared with 8.1 percent of children without mental retardation (Emerson, 2003). The reasons for this increased risk are not well known. Generally it is believed that the increased prevalence of sensory disorders, epilepsy, and brain damage associated with many specific etiologies play a role as does atypical developmental experience. It could well be that many children do not meet the criteria for a diagnosis of mental disorder but do manifest sub-threshold levels of particular symptoms that warrant intervention. The terms *behavior problems* or *behavior disorders* are often used to describe such cases.

The emphasis on studying behavioral phenotypes associated with particular etiologies has revealed co-occurring behavior problems and psychiatric disorders. These associations include attention-deficit hyperactivity disorder in fetal alcohol syndrome, anxiety in Williams syndrome, oppositional and defiant behavior in Smith-Magenis and Down syndromes, and self-injury in Lesch-Nyhan, Prader-Willi, Smith-Magenis, and Fragile x syndromes. Moreover, epidemiological studies indicate that as many as 75 percent of children with autism also have mental retardation. These children can be particularly challenging in the school setting when they exhibit property destruction, physical aggression, self-injury, and tantrums.

META-ANALYSIS

The term meta-analysis, first coined by Gene Glass in 1976, refers to a statistical technique used to synthesize data from separate comparable studies in order to obtain a quantitative summary of research addressing a common question. In 1904 Karl Pearson published what is believed to be the first meta-analysis, examining the effectiveness of a vaccine against typhoid. In 1932 Ronald Fisher, in his classic text *Statistical Methods for Research Workers*, presented a technique for combining the *p* values that came from statistically independent tests of the same hypothesis. However, meta-analysis began to gain widespread use beginning in the 1960s with the tremendous growth in social scientific research and increasing interest in its social policy implications (Chalmers, Hedges, & Cooper, 2002). During the 1970s and 1980s, many of the techniques first invented by Pearson and Fisher were rediscovered and more sophisticated techniques were developed with the work of Gene Glass, Barry McGaw, and Mary Lee Smith (1981), John Hunter, Frank Schmidt, and Greg Jackson (1982), Robert Rosenthal (1984), and Larry Hedges and Ingram Olkin (1985).

Prior to the widespread use of meta-analysis, researchers relied on a narrative approach to summarize and integrate research on a specific topic. However, traditional narrative reviews have been criticized because, although they can provide a meticulous list of multiple tests of a hypothesis, they often fail to fully and accurately integrate findings and are prone to allowing the biases of the reviewer to enter into conclusions. Just as in the traditional narrative review of research, the aim of a meta-analysis is to summarize the results of past studies, suggest potential reasons for inconsistencies in past research findings, and direct future investigations. However, although meta-analysis has the same goals as the traditional narrative review, many limitations of the narrative review can be addressed by using statistical procedures to combine the results of previous studies (Cooper & Rosenthal, 1980). In the early 2000s, meta-analysis is an accepted and respected technique across many disciplines from psychology and education to medicine and public policy.

META ANALYTIC PROCEDURES

Prior to conducting a meta-analysis, the researcher must first define the problem to be addressed by the meta-analysis, collect research relevant to the problem, and evaluate the quality of the data (Cooper, 1998). After these steps have been completed, then a meta-analysis can be conducted and the results interpreted.

Often the purpose of a meta-analysis is to answer three questions. First, does variable X have an effect on variable Y? Second, how much of an effect does variable X have on Y? Finally, are there moderating variables that can explain why the effect of X on Y varies from one study to the next? To answer the first two questions, meta-analysts will (a) calculate an effect size for the outcomes of hypothesis tests in every study and (b) average these effect sizes across hypothesis tests to estimate general magnitudes of effect and calculate confidence intervals as a test of the null hypothesis. In order to examine the question of moderating variables, meta-analysts will also (c) conduct homogeneity analyses in order to assess whether variations in outcomes exist and what features of comparisons might account for that variation, if it exists. The procedures for conducting a meta-analysis are described in detail in Cooper (1998), Cooper and Hedges (1994), Hedges and Olkin (1985), and Lipsey and Wilson (2001).

Estimating Effect Sizes. Cohen (1988) defined an effect size as “the degree to which the phenomenon is present in the population, or the degree to which the null hypothesis is false” (pp. 9–10). There are many different metrics to describe an effect size. Generally, each metric is associated with particular research designs. Although numerous estimates of effect size are available, three dominate the literature. The first, called the *d*-index by Cohen (1988), is a scale-free measure of the separation between two group means that is used when one variable in the relation is dichotomous and the other is continuous. Calculating the *d*-index for any study involves dividing the difference between the two group means by either their average standard deviation or the standard deviation of the control group. Another effect size metric is the *r*-index, or the Pearson product-moment correlation coefficient. Typically it is used to measure the degree of linear relation between two continuous variables. The third effect size metric is the odds ratio. The odds ratio is applicable when both variables are dichotomous and findings are presented as frequencies or proportions. The index is often used in studies of educational interventions when the outcome of interest is drop-out or retention rates.

Averaging Effect Sizes. The primary findings of meta-analyses are the average effect sizes and measures of dispersion that accompany them. State-of-the-art meta-

analytic procedures call for the weighting of effect sizes when they are averaged across studies. In the weighted procedure, each independent effect size is first multiplied by the inverse of its variance and the sum of these products is then divided by the sum of the inverses. The weighting procedure is generally preferred because it gives greater weight to effect sizes based on larger samples and larger samples give more precise population estimates. Confidence intervals are then calculated to test the null hypothesis that the difference between two means, or the size of a correlation or odds ratio, is zero.

Homogeneity Analyses. In addition to the confidence interval as a measure of dispersion, meta-analysts usually carry out homogeneity analyses. Homogeneity analyses allow the meta-analyst to explore whether effect sizes vary from one study to the next. A homogeneity analysis compares the amount of variance in an observed set of effect sizes with the amount of variance that would be expected by sampling error alone and provides calculation of how probable it is that the variance exhibited by the effect sizes would be observed if only sampling error were making them different. If there is greater variation in effects than would be expected by chance, then the meta-analyst can begin the process of examining moderators of comparison outcomes.

Moderator Analyses. Homogeneity analyses also allow the meta-analyst to test hypotheses about why the outcomes of studies differ. First, the meta-analyst calculates average effect sizes for different subgroups of studies, comparing the average effect sizes for different methods, types of programs, outcome measures, or participants. Then, homogeneity analyses are used to statistically test whether these factors are reliably associated with different magnitudes of effect. As previously suggested, homogeneity analyses assess whether sampling error alone accounts for variation or whether the features of studies, samples, treatment designs, or outcome measures also explain variations in the strength and/or direction of effect sizes across various groupings. This test is analogous to conducting an analysis of variance, in that a significant homogeneity statistic indicates that at least one group mean differs from the others.

Alternatively, meta-regression can be used to examine whether particular characteristics of studies are related to the sizes of the treatment effect. However, unlike the strategy previously discussed, meta-regression allows the meta-analyst to explore the relationship between continuous, as well as categorical, characteristics and effect size, and allows the effects of multiple factors to be investigated simultaneously (Thompson & Higgins, 2002).

COMPLEX DECISIONS IN META ANALYSIS

When conducting primary research, investigators encounter decision points at which they have multiple choices about how to proceed. Meta-analysts must make decisions concerning how to handle multiple effect sizes coming from the same sample since this violates the assumption of most meta-analytic procedures that effect sizes are independent data points. Meta-analysts employ multiple approaches to handling non-independent tests. Some treat each effect size as independent so that no within-study information is lost, regardless of the number that come from the same study. However, this strategy violates the assumption that the estimates are independent and results of studies will not be weighted equally in any overall conclusion about results. Rather, studies will contribute to the overall effect in relation to the number of statistical tests contained in it.

Others use the study as the unit of analysis. In this strategy, a mean or median result is calculated to represent the study. This strategy ensures that the assumption of independence is not violated and that each study contributes equally to the overall effect. However, some within study information may be lost in this approach. As of 2007 the preferred approach is to use a shifting unit of analysis (Cooper, 1998). Here, each study is allowed to contribute as many effects as there are categories in the given analysis, but effects within any category are averaged. This shifting unit of analysis approach retains as much data as possible from each study while holding to a minimum any violations of the assumption that data points are independent.

Meta-analysts also have to decide whether a fixed-effects or random-effects model of error underlies the generation of study outcomes (Hedges & Vevea, 1998). In a fixed-effects model of error, all studies are assumed to be drawn from a common population. As such, variance in effect sizes is assumed to reflect only sampling error, that is, error solely due to participant differences. In a random-effects model of error, studies are expected to vary also as a function of features that can be viewed as random influences. Thus, in a random-effect analysis, study-level variance is assumed to be present as an additional source of random influence. If it is the case that the meta-analyst suspects a large number of these additional sources of random error, then a random-effects model is most appropriate in order to take these sources of variance into account. If the meta-analyst suspects that the data are most likely little affected by other sources of random variance, then a fixed-effects model can be applied. However, it is often difficult to decide whether there may be sources of random error affecting results. Consequently, the most conservative approach is to con-

duct all analyses twice, once employing fixed-effect assumptions and once using random-effect assumptions. Differences in results based on which set of assumptions is used can be incorporated into the interpretation and discussion of findings.

ALTERNATIVE APPROACHES TO META ANALYSIS

While the inverse-variance method deriving from Hedges and Olkin (1985) described above has the most widespread use, alternative approaches to meta-analysis exist. In particular, approaches deriving from both Rosenthal (1984) and Hunter, Schmidt, and Jackson (1982) are commonly used.

Like the inverse-variance method, the Rosenthal technique converts study findings into standard index of effect and combines them to produce weighted means. However, unlike the Hedges and Olkin approach to estimate the overall significance of the effect, Rosenthal suggests combining the probabilities of each effect size. Further, heterogeneity is examined informally using diffuse and focused comparisons.

In the Hunter, Schmidt, and Jackson (1982; Hunter & Schmidt, 2004) approach, study findings are also converted into standard index of effect and combined to produce weighted means. However, untransformed effect size estimates weighted by the sample size of the study are used to compute the weighted mean effect size. Further, heterogeneity in effect sizes across studies is examined by comparing the observed variation in obtained effect sizes with the variation expected due to sampling error, that is, the expected variance in effect sizes given that all observed effects are estimating the same underlying population value. However, a formal statistical test of the difference between these two values is typically not carried out. Rather, the meta-analyst adopts a critical value for the ratio of observed-to-expected variance to use as a means for rejecting the null hypothesis. In this approach, the meta-analyst might also adjust effect sizes to account for methodological artifacts such as sampling error, range restrictions, or unreliability of measurements. This method has been applied most often in the areas of industrial and organizational psychology.

ADVANTAGES OF META ANALYSIS

There are a number of advantages of meta-analysis over traditional narrative techniques for synthesizing research (see Rosenthal & DiMatteo, 2001, for a full review). First, the structured methodology of meta-analysis requires careful review and analysis of all contributing research. As such, meta-analysis overcomes much of the bias associated with the reliance on single studies or subsets of studies that inevitably occurs in narrative

reviews of a literature. Second, meta-analysis allows even small and non-significant effects to contribute to the overall conclusions and avoids wasting data because a sample size was too small and significance was not achieved.

Third, meta-analysis allows the synthesist to ask questions about variables that moderate effects. Specifically, even if no individual study has compared results of different methods, types of programs, outcome measures, or participants, by comparing results across studies the synthesist can get a first hint about whether these variables would be important to look at in future research and/or as guides to policy. Without the aid of statistics, the synthesist simply examines the differences in outcomes across studies, groups them informally by study features, and decides whether the feature is a significant predictor of variation in outcomes. At best, this method is imprecise. At worst, it leads to incorrect inferences. In contrast, meta-analysis provides a formal means for testing whether different features of studies explain variation in their outcomes.

LIMITATIONS OF META ANALYSIS

Despite many advantages, meta-analysis has been criticized for a number of legitimate limitations and concerns. First, while many meta-analysts go to great lengths to locate as much relevant research as possible, missing data as a result of the literature search procedures on the part of the synthesist or data censoring on the part of primary researchers, editors, or publishers is often inevitable. When data are systematically missing, not only is the size of the sample gathered for the research synthesis reduced, but the representativeness of the sample and the validity of the results are compromised, regardless of the quality of the meta-analysis in all other respects (Rothstein, Sutton, Borenstein, 2005). A number of techniques have been developed in order to assess the possible presence of data censoring and the implications of this threat to the validity of the conclusions drawn from the meta-analysis (see Rothstein, Sutton, Borenstein, 2005, for full review).

Second, meta-analysis is sometimes criticized for combining research of varying quality using various methods and samples. Because a meta-analysis is only as good as the primary research it is cumulating, it is important that the meta-analyst believes that each finding is testing the same relationship and that the primary researchers made valid assumptions when they computed the results of their statistical tests. Of course, research quality can also be used as a moderator variable in the meta-analysis.

Third, while educational psychology research often examines the combination and interaction of many variables in multifactorial models, including regression analyses,

meta-analysis is focused on individual effects. Consequently, there is some loss of information in meta-analysis because it remains difficult to include studies in which complex models were used to analyze data.

Finally, synthesis-based evidence should not be interpreted as supporting statements about causality. When different study characteristics are found associated with the effects of a treatment, the synthesist should recommend that future researchers examine these factors within a single experiment.

DIRECTING RESEARCH AND INFORMING EDUCATIONAL POLICY

With the ever growing volume of primary research on various education related topics, meta-analysis has become an essential tool among school policy makers and practitioners for coping with the overwhelming number of results. In the early 2000s, meta-analysis is often used to guide policy and practice in the classroom. Topics have ranged from the effectiveness of homework, access to special education, or the relationship between class size and achievement to the effect of providing rewards on intrinsic motivation or the relationship between race and achievement motivation. Further, often a synthesis of the current research leaves as many questions unanswered as it answers. However, it provides a comprehensive guide to direct future research. Clearly, the synthesist faces a number of complex issues in conducting a meta-analysis. However, if social science research is to contribute to rational decision making, then rigorous, systematic syntheses of research are a most critical component in researchers' methodological toolbox. Meta-analysis facilitates the attainment of these necessary standards.

METACOGNITION

Learning depends, in part, on the effective use of basic cognitive processes such as memory and attention, the activation of relevant background knowledge, and the deployment of cognitive strategies to achieve particular goals. To ensure that the basic processes are used effectively, that the activated knowledge is indeed relevant, and that appropriate strategies are being deployed, learners also need to have awareness and control of their cognitive processes. This higher-level cognition was given the label metacognition by American developmental psychologist John Flavell (1976).

The term metacognition literally means cognition about cognition, or more informally, thinking about thinking. Flavell defined metacognition as knowledge about cognition and control of cognition. The knowledge component encompasses what one knows about cognition, including knowledge about oneself as a learner, about aspects of the task at hand, and about strategies needed to carry out the task effectively. The control component encompasses the strategies one uses to make cognitive progress, such as planning how to approach a task, evaluating progress as the task is being completed, and changing tactics if difficulties arise.

HISTORICAL ROOTS OF INQUIRY IN METACOGNITION

Research on metacognition had its origins in the 1970s work of Flavell (1976, 1979) and another prominent developmental psychologist, Ann Brown (1943-1999). This work focused on children's metamemory, that is, their knowledge and control of their memory processes. In a landmark study, Kreutzer, Leonard, and Flavell, interviewed children in kindergarten and grades 1, 3, and 5 to determine their knowledge of how their memories work. Open-ended questions were asked about a variety of hypothetical situations tapping knowledge of person, task, and strategy variables influencing memory. For example, children were asked how they could be sure to remember to take their skates to school with them the next day and how they would remember a phone number, and whether it would be easier or harder to remember a list of words they had already studied. Responses revealed that even the youngest children had some knowledge of the workings of their memory, but that older children had greater insights.

Brown's early interest in metacognition was reflected in the title of a 1978 chapter, "Knowing when, where, and how to remember: A problem of metacognition." Her 1970s research on how well children were able to assess their readiness to be tested on recall of simple materials, such as pictures of common objects, evolved naturally into research on the role of metacognition in studying academic materials and comprehending prose. Her 1980 chapter in a book on theoretical models of reading introduced metacognition to the community of reading researchers and helped to fuel the most active line of domain-specific inquiry in metacognition.

Although Flavell and Brown are credited with introducing the term metacognition, they were not the first to study phenomena that was to be called metacognitive. From the beginning of the twentieth century reading researchers were documenting the importance of monitoring and regulating one's comprehension processes. Memory researchers were studying feelings of knowing and memory monitoring from at least the 1960s. Information processing models from the 1970s included executive control systems that regulate basic cognitive processes.

In addition, Soviet psychologist Lev Vygotsky (1896-1934) and Swiss psychologist Jean Piaget (1896-1980) included processes regarded as metacognitive in their theories of children's thinking. Vygotsky theorized that children develop the capacity for self-regulation through interaction with more knowledgeable others. These individuals initially assume responsibility for monitoring progress, setting goals, planning activities, allocating attention, and so on. Gradually, responsibility for these executive processes is given over to the child, who

becomes increasingly capable of regulating his or her own cognitive activities. This transition from other-regulation to self-regulation is in the early 2000s regarded as a hallmark of metacognitive development. Piaget theorized that peers challenge one another's thoughts and thus advance their cognitive development. Inducing children to reflect on their own thinking is in fact inducing metacognition.

Vygotsky's theory provides the foundation for contemporary classroom interventions that begin with explicit instruction on the part of the teacher, followed by modeling and guided practice of cognitive and metacognitive strategies, with a gradual release of responsibility to the student.

Piaget's theory has been built upon by contemporary researchers, including Palincsar and Brown, to reveal that peer discussion and collaboration help students to monitor their own understanding and build new strategic capabilities.

IMPORTANCE OF METACOGNITION IN THEORIES OF LEARNING AND INSTRUCTION

The implicit focus on metacognitive processes in early theories of information processing and cognitive development gave way to an explicit focus in contemporary theories of learning and instruction. Within a decade of the seminal work of Flavell and Brown, hundreds of laboratory studies had accumulated showing that metacognitive knowledge and control were associated with more successful cognitive performance, and applied research confirmed the practical importance of metacognition in the classroom. When students have knowledge and control of their own cognitive processes, learning is enhanced; this assertion holds regardless of the domain of learning, whether reading, writing, science, mathematics, or any other activity that involves thinking.

Evidence that metacognition is firmly entrenched in theorizing about how students learn comes from two influential national committees charged with reviewing and synthesizing the research on learning in the 1990s. Early in the decade a taskforce of the American Psychological Association, under the leadership of Nadine Lambert and Barbara McCombs, developed a set of learner-centered psychological principles intended as guidelines for school redesign and reform. Informing the principles was a model of learning that integrated the following factors: cognitive, metacognitive, motivational, affective, developmental, social, and individual differences. Metacognition was featured in one of the 14 learner-centered principles: "Thinking about thinking: Higher order strategies for selecting and monitoring mental operations facilitate creative and critical thinking." In justifying this principle the authors noted that instructional approaches

that foster metacognition can enhance not only student learning but also student responsibility for learning.

Later in the 1990s a committee of the National Research Council, led by John Bransford, Ann Brown, and Rodney Cocking, similarly concluded that metacognition is a key factor in learning that should be deliberately cultivated. They emphasized the particularly important role that metacognition plays in promoting transfer of learning. That is, students can more readily apply knowledge acquired in one context to another context if they have more awareness of themselves as learners, if they monitor their strategies and resources, and if they assess their readiness for tests and other performances.

Although metacognition is a term that may still need to be defined to the general public, it is well represented in most college-level textbooks in cognitive, developmental, and educational psychology. Further information about the role of metacognition to learning and instruction can be found in numerous articles, chapters, and edited books, including those by DeSoete and Veenman; Hacker, Dunlosky and Graesser; Hartman; Israel and colleagues; Miller; Paris; Schneider and Lockl; Schraw and Impara; and Sternberg.

DEVELOPMENTAL AND INDIVIDUAL DIFFERENCES IN METACOGNITION

The early research on metacognition was conducted by developmental psychologists whose particular interest was in age-related changes. Flavell, Brown, and their colleagues documented substantial growth in knowledge and control of memory. Researchers demonstrated similar developmental trends in other cognitive enterprises, including communication, comprehension, problem solving, and attention. A consistent pattern in the domain of reading documented in the early years by Baker and Brown but still found in the early 2000s is that younger readers have little awareness that they must attempt to make sense of text; they focus on reading as a decoding process, rather than as a meaning-getting process.

Metacognitive growth is gradual throughout childhood, adolescence, and even into adulthood.

One cannot simply assert that an individual has or does not have metacognition. Metacognition is not a unitary construct, either across domains or within domains, nor is the deployment of a metacognitive strategy all or none. There are degrees in the effectiveness with which strategies can be applied. Children show primitive abilities to plan and check their activities on simple tasks during the preschool years, but even advanced students in higher education show metacognitive limitations on more difficult tasks.

A parallel line of inquiry that grew up alongside the developmental work focused on individual differences in metacognition, typically involving comparisons of better and poorer students, or students with and without a learning disability. Again, the pattern has been quite consistent, with better students demonstrating more knowledge and control of the processes involved in a given domain, whether it is studying, reading, writing, mathematics, or scientific problem solving. Ability-related differences in knowledge about cognition, like developmental differences, have been documented in countless studies, across age groups ranging from early childhood through later adulthood.

The compelling body of descriptive evidence that younger and less-skilled students have limited metacognitive knowledge and control led psychologists to ask whether metacognition could be deliberately fostered and if so, whether it would enhance children's success in school. Experimental research conducted as early as the 1980s provided an affirmative answer. Although the evidence became clear that increasing students' metacognitive awareness and control can improve learning, Baker points out that the relation between metacognition and learning is not unidirectional. Rather, reciprocal causation is most likely; that is, improvements in metacognition contribute to improvements in learning, which in turn contribute to further improvements in metacognition.

ASSESSMENT OF METACOGNITION

A variety of approaches have been used to measure metacognition, and considerable controversy exists as to the best ways to assess it. The tools that one selects must be suited to the developmental levels of the students and the purposes of the assessments. Multiple measures are recommended because they can provide converging evidence; if the same findings are obtained with different tools, the researcher or educator can be more confident in his or her conclusions.

The most frequently used approach to assess both metacognitive knowledge and metacognitive control is to ask students directly what they know or what they do while engaging in particular cognitive activities. Verbal reports are typically elicited through structured interviews, such as that originally used by Flavell, or by questionnaires that include multiple response options to a series of items. Most questionnaires are domain specific (e.g., they focus only on reading or only on math), but some are intended to be more domain general. A domain-specific inventory might tap a student's understanding of variables that affect reading outcomes and of strategies that are effective for comprehending text. An example of a well-validated inventory is Mokhtari and Reichard's Metacognitive Awareness of Reading Strategies Inventory. A domain-general inventory might assess an individual's knowledge

about cognition (including declarative, procedural, and conditional knowledge) and regulation of cognition (including planning, monitoring, debugging, and evaluating learning). An example of a well-validated inventory is Schraw and Dennison's Metacognitive Awareness Inventory. Another valuable self-report option for assessing metacognitive control is to ask students to think aloud about what they are doing and thinking as they solve a problem or read a text.

Technological advances have led to more sophisticated and sensitive ways of assessing metacognitive control. Students can be asked to engage in a task while process measures are being collected online. For example, to assess metacognitive control during reading, a passage may be presented to the reader on a computer screen. Patterns of movement through the text are collected automatically, revealing whether the reader paused at a particular point, whether he or she looked back at previous text, or whether he or she jumped ahead. In many cases, the texts participants read contain errors that were deliberately introduced to make the text difficult to understand. Patterns of movement through the texts reveal processes of comprehension monitoring, or the lack thereof. These process measures are often supplemented by asking readers to reflect on what they were thinking or to answer follow-up comprehension questions. Online processing tasks can also be used to track cognitive monitoring while performing other activities such as mathematical problem solving, writing, computer programming, and vocabulary learning. An advantage of these approaches is that they reveal what students actually do instead of what they say they do. Research using online measures reveals the same developmental and ability-related differences documented through verbal reports.

Still another general approach to assessing metacognition is used primarily by researchers studying basic cognitive processes. In judgments of learning tasks, students are presented with to-be-learned material, such as a list of words or a passage, and they are given a test over the material. They are then asked to judge how well they learned the material or how well they answered the comprehension questions. Judgments of learning are then examined in relation to actual performance. A related approach assesses feelings of knowing or knowledge monitoring; it involves presenting students with material and asking them how well they think they would perform on a test. For example, they might be presented with a list of vocabulary words and asked how many they would be able to define or a set of math problems and asked how many they can solve. They are then asked to complete the task, and their performance is compared to their predictions. Even students at the college level generally are not very good at monitoring their learning, but research has shown that a host of factors influences their success, such

as item difficulty and familiarity of the to-be-learned materials, and that they can be taught to monitor more effectively.

Researchers are the most frequent users of metacognitive assessments, but classroom teachers and school psychologists have also become interested in evaluating their students' metacognitive knowledge and control. According to Baker and Cerro, it is important to be mindful of the limitations of the tools that are used and the conclusions that can be drawn. For example, a limitation of questionnaires is that there is not necessarily a correspondence between what people say they do and what they actually do. Comparisons of questionnaire responses with performance measures on a given task often yield rather low correlations. In addition, people often respond according to what they think they should say, rather than what they actually believe or do. Despite their limitations, verbal reports can be valid and reliable sources of information about cognitive processes when carefully elicited and interpreted, as can more direct processing measures.

INSTRUCTIONAL IMPLICATIONS

Classroom-based intervention studies began to be implemented in the 1980s shortly after laboratory studies provided solid evidence that metacognitive knowledge and control could be fostered through direct instruction. These interventions typically are domain specific, undertaken not with the goal of increasing metacognition for its own sake, but rather with the goal of increasing learning. Teacher-led interventions using metacognitively oriented reading instruction have resulted in gains in students' metacognition as well as comprehension. One program developed by Michael Pressley and colleagues, known as Transactional Strategies Instruction, is effective with children as early as second grade. Similarly, teacher-led interventions have been devised and successfully implemented to help students plan, monitor, and evaluate their own thinking during mathematical problem solving. Peer collaboration and discussion play a vital role in the classroom as students make explicit their cognitive processes, assumptions, and strategies. Evidence that metacognitive intervention is effective is in the early 2000s so strong that disciplinary organizations and national panels recommend that metacognition be included in teacher preparation and in classroom curricula.

MICROGENETIC RESEARCH

How do children learn? Developmental or educational psychologists would seem to be the experts to turn to in seeking answers to this question. Yet, for a long time, developmental psychologists devoted themselves to understanding how children's knowledge and understanding changes, but they did not directly examine the process by means of which these changes occur. Instead, the typical method was to study what children of one age understand and compare that to what children a few years older understand. Researchers then made inferences about what developed between the two ages. But clearly these inferences were indirect. No one had observed the change occurring within the individual child.

THE 1982 RESEARCH BY KUHN AND PHELPS

The microgenetic method has changed this. Its goal is direct observation of the change process as it occurs in individual children.

Its defining characteristic is that an individual encounters the same or similar problem over frequent occasions, allowing the researcher to observe how the individual's approaches to the problem change over time. Although the method has precursors in the work of Werner (1948), the first modern study featuring the microgenetic method was published by Kuhn and Phelps in 1982. They observed fourth grade students engaged in a scientific inquiry task. Students observed that one combination of liquid chemicals (e.g., A, B, and C) turned the mixture cloudy and another combination (e.g., B, C, and D) did not. The student's task was to experiment with the set of liquids to determine which of the individual liquids played a role in producing the chemical change and which did not.

Students of this age found the task difficult and typically did not succeed in drawing valid conclusions during their first attempt. But the critical feature of the method is that the student encounters the task not just once but a number of times, typically over a period of weeks or months. What Kuhn and Phelps observed is that over this course of time most students' performance improved in two ways. First, the conclusions got better. A student was more likely to correctly identify the components of the mixture that played a causal role in producing the outcome, as well as identify those components that played no causal role. But second, and equally important, the strategies by means of which a student generated those conclusions also underwent change. Specifically, the student displayed a number of different strategies to apply to the problem, and what changed over time was the frequency with which they were applied. More advanced and effective strategies—the ones that yielded valid conclusions—began to be used more frequently, while the less advanced, ineffective strategies that led to invalid conclusions became less frequent.

Exactly how did this change take place? Kuhn and Phelps found that some, but only a minority, of children showed an abrupt shift from predominant use of weak strategies to predominant use of strong strategies. These individuals discovered the best way to approach the problem quite suddenly, their approach took a sharp turn, and they rarely used the poorer strategies again. These children, however, were in the minority. For the majority of children, change took place much more gradually as better strategies increased in frequency and poorer ones decreased. Moreover, this change was not a smooth, continuous one. A better strategy might appear once but then not be used again until several sessions later. Or once this better strategy became predominant, a weak strategy that had not been used for some time might reappear. Change, in other words, was overall in a positive direction, but the progress was not even or constant.

An implication is that change entails two components: consolidation and mastery of the stronger strategies, leading

to more frequent usage and inhibition of the weaker strategies. Both are necessary for success. Much of the evidence from microgenetic studies suggests that the inhibition component may be the more challenging of the two. This conclusion is significant because it reverses previous conceptions of development.

A SIMILAR PROCESS ACROSS DIVERSE DOMAINS AND AGE GROUPS

Other studies since the one by Kuhn and Phelps have confirmed these basic findings over a wide range of cognitive tasks, including many that figure prominently in classroom instruction, and age groups. (For reviews of research see Siegler & Crowley, 1991; Kuhn, 1995; Miller & Coyle, 1999; Siegler, 2006). Chen and Siegler (2000), for example, observed changes in frequency of usage among 2-year-olds in the multiple strategies they exhibited to reach a desirable out-of-reach toy—reaching with their hands, asking for an adult's help or using an available tool. Siegler and Chen (1998) observed the strategies of 5-year-olds over time in making judgments about the operation of a balance scale. Alibali (1999) identified and followed over time ten different strategies that third and fourth graders used in solving mathematical equality problems ($3 + x = 9$). Thornton (1999) studied 5-year-olds playing the game of Twenty Questions.

Not only did she see strategy change over time; she also found that the type of strategy that was initially predominant was predictive of the degree of progress children showed. Children who initially asked only entirely specific questions (“Is it the red car?”) were less likely to progress than were those who initially included at least some less specific questions (e.g., “Is it the car?”) in their repertoires. These were the children most likely to progress to consistent usage of the most effective strategies (e.g., “Is it one of the cars?”) Other studies have similarly found initial variability to be a predictor of change.

The microgenetic method has produced many of the kinds of changes with practice in school-related tasks that educators hope to see, making it possible to better understand them (Kuhn, 2005). Dean and Kuhn (2007) used a microgenetic method to follow changes over time in fourth graders' scientific reasoning. Students had to discover which of multiple potential variables did and did not make a difference to an outcome, as they worked on multiple problems over a number of months.

Dean and Kuhn found not only that students' knowledge and the strategies used to generate that knowledge improved over time, but also that this improvement was better maintained, compared to a condition involving brief direct instruction of the effective strategy.

Finally, Kuhn, Goh, Iordanou, and Shaenfield (in press) observed change over time in sixth graders' argumentation strategies as they worked in pairs debating a social issue with a pair of peers who held an opposing view. Although they received no formal instruction, their argumentation skills showed improvement when assessed individually (without peer support) on a new topic.

LEARNING AND DEVELOPMENT

How and why does the microgenetic method work? Ideally, frequent exercise serves simply to speed up the change process, allowing the researcher to examine it, without altering its essential characteristics. A concern is that this acceleration might change characteristics of the process, if so limiting what can be learned about such changes as they occur in an entirely natural environment. Studies that have compared change patterns under microgenetic conditions with those observed over a much longer time period using longitudinal methods, however, find that the patterns observed under the two conditions are comparable (Siegler & Svetina, 2002). What differs is the length of time over which they take place.

But this does not mean that there is no difference between the comparatively rapid cognitive changes that have typically been called learning and the slower changes that have been referred to as development. The distinction between development and learning is a long-standing one that has been important to developmental psychologists, and there is no indication that it should be discarded.

While the microgenetic method has contributed to making the dividing line between learning and development less firm than it was once thought to be, it does not follow that there remain no useful distinctions at all. Learning what songs are on this week's Top 10 List and learning that conflicting ideas can both be right are different kinds of learning in numerous important respects (among them generalizability, reversibility, and universality of occurrence). What is important is recognizing the process of change as one that has multiple parameters. When the process is examined microgenetically, it becomes possible to begin to characterize it in terms of many such parameters. The distinction between development and learning is also indicated by the fact that microgenetic studies have typically shown change to occur more rapidly in older children or adults than in their younger counterparts (Kuhn & Pease, 2006; Kuhn, Garcia-Mila, Zohar, & Andersen, 1995). The older individuals apparently bring something to the learning process that the younger ones have not yet developed.

METASTRATEGIC MANAGEMENT

Another important question that has been asked about the strategy change that microgenetic studies reveal is the

degree to which it occurs under the individual's conscious monitoring and control. Because inhibition of less effective strategies is involved, the development of conscious awareness, monitoring, and management of one's own learning processes executive or metastrategic functions have been suggested as playing an important role. Some microgenetic researchers, such as Siegler (2000, 2006; Siegler & Jenkins, 1989), emphasize the need for associations with the more frequent, less effective strategies to be weakened, as well as associations with more effective strategies strengthened. Others, such as Kuhn and colleagues (Kuhn, 2001; Kuhn & Dean, 2004) emphasize relinquishment of less effective strategies as a more formidable obstacle than strengthening new ones. These researchers propose that knowledge at a meta-level is as important as that at the performance level and plays a major role in what happens there. If so, the changes that occur at the strategic level in microgenetic studies should be accompanied by changes at the metastrategic level and studies by Kuhn and colleagues provide evidence that this is the case (Dean & Kuhn, 2007; Kuhn & Pearsall, 1998; Kuhn, Garcia-Mila, Zohar, & Andersen, 1995).

In the study by Kuhn and Pearsall, for example, during repeated engagement over several months with a scientific investigation task students were asked at several points to explain to a new student how to do the task. This measure of metastrategic understanding showed advances over time, as did measures of strategic performance. Kuhn and Pease (2006) showed that metastrategic monitoring and management of performance also increase over longer periods of time, as a part of normal cognitive development. They studied the performance of 12-year-olds and young adults in learning a simple set of causal relations, and they attributed the adults' superior performance to enhanced meta-level monitoring and management.

MICROGENETIC RESEARCH IN THE CLASSROOM

Although classroom teachers are unlikely to use it to conduct formal research studies, the microgenetic method clearly has a place in the classroom. Teachers are using the microgenetic method in an informal, naturalistic way when they assign their students the same or a similar task repeatedly over a period of time, for example, to carry out two-digit multiplication or to select a book to read and to write a book report on it. Teachers expect to see changes over time in the strategies a student brings to bear on the task and in the product that results. The findings from more formal microgenetic research offer teachers a framework for conceptualizing and monitoring such changes. They suggest that teachers have many strategies they might usefully consider in observing a student's progress over time. These include not only the product of the student's efforts the work the student submits for a grade but also what strategies the student has applied to generate this

product, how the individual has changed over time, whether the student needs more help in inhibiting ineffective strategies or in consolidating the use of effective ones, and, perhaps most significant of all, what progress the student is making in coming to monitor and manage his or her own learning.

Deanna Kubn

MIDDLE SCHOOL, TRANSITION TO

SEE *School Transitions: Middle School*.

MIDGLEY, CAROL 1933–2001

Carol Midgley was born in 1933 and grew up on Long Island, New York. For her undergraduate education, she attended the University of Vermont, where she met her future husband, Rees. The couple moved to Ann Arbor, Michigan, in 1961, where they raised their three children. Carol Midgley devoted much time to volunteer work, particularly in education. She was an activist whose mission was to improve public schools. Her efforts led to the implementation of open classrooms and “small houses” in local elementary and middle schools; she later worked with other members of her community to create Community High School, a school designed to focus on the academic and socio-emotional need of early adolescents.

Midgley returned to graduate school in the 1980s and received her Ph.D. in educational psychology from the University of Michigan in 1987. Her research focused on academic motivation during adolescence, with a particular emphasis on early adolescence. At Michigan, Midgley engaged in collaborative work with her mentor, Jacquelynne Eccles. They worked on a study designed to examine why women often opted out of studying mathematics, even when their performance was good. Midgley then worked on a large-scale study with Eccles, Allan Wigfield, and other colleagues, examining the transition from elementary school into middle school (MSALT: The Michigan Study of Adolescent Transitions). That study was originally designed to examine changes in expectancies and values in early adolescents as they transitioned from elementary school into middle school. It was the first study of school transitions that examined both within-year and between-year changes in motivation. Results of the study indicated that students’ expectancies and values do change as students move into

middle school, and these changes are often in a negative direction. The focus on changes in expectancies and values of early adolescents across the transition countered the commonly held assumption that the observed drop in motivation was due to puberty.

Midgley and Eccles used stage-environment fit theory to explain these negative shifts in motivation. They argued that the environment in middle school was antithetical to the developmental needs of early adolescents, and that this mismatch between school environments and adolescents’ needs contributed to the downward shift in motivation. As an example, they noted that early adolescents need cognitively challenging and interesting work, whereas the curricula that are presented in many middle schools are often repetitious and boring.

When later asked about Midgley’s work on collaborative projects, Eccles noted that Midgley’s involvement in all of these projects was critical: “We couldn’t have done it without her.”

In 1989 Midgley accepted a position as a research scientist in the Combined Program in Education and Psychology at the University of Michigan. There, Midgley began a long collaboration with Martin Maehr and also began mentoring her own graduate students. At this time, Midgley became particularly interested in goal orientation theory. Her career shifted at this point as she dedicated much of her future work to her original interest in school reform.

Midgley and her colleagues first worked in elementary schools, helping teachers to focus instruction on mastery goals (i.e., effort, improvement, and self-comparisons). Midgley then received funding from the U. S. Department of Education to work with educators on school reform, using a goal theory approach. Along with Maehr and their graduate students, Midgley immersed herself in collaborative work with several elementary and middle schools in Michigan. The goal of these studies was for educators to examine the types of achievement goals that they foster in their students (i.e., mastery or performance goals), and then to work with those educators to change instructional practices, so that the focus of instruction would be on mastery rather than performance. This work was both arduous and inspiring; it resulted in many publications and a book co-authored with Maehr. The work demonstrated that goal theory could be used to effectively guide school reform, and that educators could change their practices to focus on mastery.

Midgley later received funding from the William T. Grant Foundation to study the development of achievement goals during adolescence. This longitudinal work examined changes in goals and goal structures, as well as the relations of these changes to adolescent well being. Midgley also received funding, with her colleague Julianne Turner, from the Spencer Foundation; that study examined students’ avoidance beliefs

and behaviors in mathematics classrooms before and after the transition into middle school. The study used both quantitative and qualitative methods to examine the effects of instructional practices on avoidance behaviors. Result of the study indicated that students displayed fewer avoidance behaviors (i.e., self-handicapping, avoidance of help-seeking) when students perceived a mastery goal structure in math classrooms.

Under Midgley's direction, she and her students developed the Patterns of Adaptive Learning Survey (PALS). The PALS is an instrument that measures personal goal orientations and classroom goal structures. The instrument is widely recognized in the field. It has been translated into several languages and used with many thousands of students across the world.

Midgley died in 2001. Her legacy lives on, as her work on adolescent motivation continues to influence both research and policy in the United States and abroad. She is arguably one of the most cited researchers in the field of academic motivation. She mentored a large group of graduate students who continue to pursue her goals of improving education for adolescents.

The Students of Dr. Carol Midgley

MISDIAGNOSES OF DISABILITIES

Focus on misdiagnoses of special education disabilities has centered predominately on the overrepresentation of Black males in mental retardation classrooms. While it is unknown how many misdiagnoses occur each year, they have been systematically and historically documented across all ethnic minority populations (e.g., Hispanic, Native American, and Asian American) and special education categories (Reschley, 1981). Indeed, ethnic disproportionalities have been reported in specific learning disability (Barona, Santos de Barona, & Faykus, 1993; Payette & Clarizio, 1994) and in emotionally disturbed (Harris-Murri, King, & Rostenberg, 2006; Yeh, Forness, Ho, McCabe, & Hough, 2004), whereas in gifted and talented classrooms, ethnic minorities and females are under-represented and have a lower retention rate than their white, male counterparts (Moore, Ford, & Milner, 2005).

Based on these findings, researchers in psychology and education have emphasized the importance of cultural sensitivity and awareness in professionals who refer, test, and diagnose disabled children, especially minorities. In particular, the ways in which standardized tests are used and interpreted have been criticized given the weight an IQ score has on every special education diagnosis (e.g., Reschley, 1981). Because of an IQ phenomenon known as the Flynn effect, however, each one of the over 2 million children who are evaluated every year on IQ tests as part of their special education evaluation is at risk for misdiagnosis, regardless of ethnicity and gender.

USE OF IQ IN DETERMINING DIAGNOSES AND SERVICES

IQ tests are used in all special education diagnosis decisions, but they play a fundamental role in mental retardation (MR) and specific learning disability (SLD) diagnoses. Under federal guidelines, a child who displays "significantly subaverage general intellectual functioning, with deficits in adaptive behavior, and manifested during the developmental period (prior to age 18), that adversely affects a child's educational performance" will receive MR services (*Assistance to States for the Education of Children with Disabilities*, 2006, p. 46756). While each state has the flexibility to develop its own criteria (as long as it does not conflict with the criteria set forth by IDEA), "significantly subaverage general intellectual functioning" is usually determined by an IQ score of 70 points or below, as recommended by the American Psychiatric Association (APA, 1994) and the American Association of Intellectual and Developmental Disabilities (formerly known as the American Association of Mental Retardation; AAMR 1992). Often, obtaining an

IQ score below the cut-off of 70 points is enough to meet the criteria for mental retardation or MR.

Under the same guidelines, SLD is defined as “a disorder in one or more of the basic psychological processes involved in understanding or in using language, spoken or written, that may manifest itself in an imperfect ability to listen, think, speak, read, write, spell, or to do mathematical calculations” (*Assistance to States for the Education of Children with Disabilities*, 2006, p. 46757). There is much variability, however, between states on the ways in which SLD is diagnosed. A commonly used method is to determine if a student’s IQ is significantly higher than his or her achievement test score, although this methodology is highly criticized among researchers and practitioners (e.g., Reschley & Hosp, 2004) and is no longer required in the Code of Federal Regulations. Regardless, a child must display at least average intellectual functioning (usually defined as an IQ of 85 points or higher) in order to qualify for SLD services. Thus, many educational diagnoses require scoring above or below a specific IQ score cut-off to qualify.

SLD is an umbrella term for a diverse array of cognitive disabilities that can range from brain injury to dyslexia. Therefore, services can range from providing students with extra time on tests to hiring resource room specialists. While the latter services can be costly, they are implemented less frequently than the former services, which are substantially less expensive. Therefore, while SLD is the most common special education diagnosis, accounting for almost half (48.5%) of the five million children in special education in 2002 (U.S. Department of Education, 2004), the costs of providing SLD services can vary widely.

MR, by contrast, is far less frequently diagnosed, accounting for less than 10% of the special education population (U.S. Department of Education, 2004). It is, however, a more consistent and costly set of services, compared to SLD. Common services offered to MR students include modified regular assignments and more extensive educational interventions, such as receiving one-to-one instructions in a self-contained classroom, instruction from specialists, and trained aides (Singer, Butler, Palfrey, & Walker, 1986).

THE FLYNN EFFECT

The Flynn effect refers to the steady rise in IQ scores seen between 1945 and the early 2000s. It is named after James Flynn (1984, 1987), the political scientist credited with its most extensive documentation. Flynn and others (e.g., Te Nijenhuis & Van der Flier, 2007; Rodgers & Wanstrom, 2007) have observed this systematic IQ rise in 29 nations, spanning 5 continents, including both developed and developing nations. The estimated magni-

tude of these gains range between 5 to 25 points within a single generation, depending on the country and type of IQ test used. In the United States, this rise is estimated to be approximately 3 points a decade on the Wechsler Intelligence Scale for Children (WISC) and the Stanford-Binet measures.

The reason for the wide range in gains between (as well as within) countries can be attributed to the IQ test that is used. Gains are higher on measures that rely heavily on tests of fluid abilities, or on-the-spot reasoning and abstract abilities, than they are on tests of crystallized abilities, or accumulated knowledge. Tests of crystallized intelligence, such as the vocabulary and arithmetic subtests on the WISC, show very small gains (only 2 to 3 points) between 1947 and 2002. Whereas subtests tests that measure abstract reasoning, visual cognition, on-the-spot reasoning, and working memory show gains up of 25 points during the same time period (Flynn, 2007).

The Flynn effect is measured in terms of IQ gains that result from people doing significantly better on an old IQ test that was created as far back as 25 years before their time (and has not been changed in that interval) when compared to their performance on a more current test whose content has been updated. In other words, as IQ test norms get older, people perform better on them, raising the mean IQ by several points within a matter of years. Specifically, within 20 years, the average IQ in the U.S. population rose from 100 to 106. To compensate for this upward creep, IQ tests are re-normed, at which point the test is made harder. Re-normed tests reset the mean back to 100, which in turn, hides the previous gains from the old norm. Therefore, the same person will score higher on an outdated, old IQ test compared to a brand new IQ test, even if both tests are administered on the same day.

THE FLYNN EFFECT AND MR/SLD DIAGNOSES

Given the fluctuations in IQ created by the Flynn effect when old IQ tests are re-normed, coupled with the heavy use of IQ cut-off scores, the diagnoses of MR and SLD are problematic. While scores rise and thus as more students surpass the 70 IQ cut-off, fewer students are classified MR. Similarly, more students are classified SLD as more students surpass the 85 IQ cut-off. Thus, the discrepancy between IQ and achievement widens. Both of these trends occur regardless of the students’ actual cognitive ability. When scores fall with the onset of new IQ norms, these diagnostic trends will reverse; suddenly, MR diagnoses will increase, while SLD diagnoses will decrease. Again, these changes will occur not because the child’s cognitive ability has changed but because the child was tested on a new IQ norm.

While Flynn's seminal analyses excluded individuals with cognitive disabilities, several studies have directly explored the Flynn effect among children in special education. Many researchers have reported that children receiving special education services lose, on average, some 5 to 9 IQ points when tested on a newly normed IQ test (e.g., Wechsler, 1991). More alarmingly, Kanaya, Scullin, and Ceci (2003), using a nationally diverse sample, found that over 30% of the students in their sample who tested above the MR cut-off score of 70 points on the WISC-R (Wechsler 1974) tested below the cut-off when retested on the newer normed WISC-III (Wechsler, 1991). This, in turn, resulted in a threefold increase in MR diagnoses, simply due to the test norms used and the year tested even though the students' actual cognitive ability did not decline.

In addition, among children initially diagnosed with SLD on the WISC-R, Gaskill and Brantley (1996) found that more than 40% of the students in their sample no longer met the criteria for SLD when retested on the newer, harder WISC-III. This finding was replicated by Truscott and Frank (2001) who found that the number of SLD diagnoses in a school district decreased with the introduction of the new norm as students no longer had a significant discrepancy between their IQ scores and achievement test scores.

Therefore, MR and SLD students were measured as having a significant drop in IQ when retested on a newer norm, and this drop often leads to a change in their diagnosis. More in-depth analyses also suggest there are individual differences in the Flynn effect. For example, Kanaya, Ceci, and Scullin (2005) discovered a larger Flynn effect among younger children tested on the original WISC norms (Wechsler, 1949), compared to older children on subsequent WISC-R norms. In addition, findings by Sanborn, Truscott, Phelps, and McDougal (2003) suggest that the Flynn effect is diminished in SLD children at lower IQ levels when compared to SLD children at higher IQ levels.

RESEARCH IMPLICATIONS FOR PROFESSIONALS

Due to the Flynn effect and the use of IQ cut-off scores in special education policies, children are diagnosed based on the year tested and test norms used rather than their actual cognitive ability. Therefore, children who are tested on old IQ norms and misdiagnosed due to their inflated scores will not qualify for or receive the resources of the appropriate education that is guaranteed to them by law. After the initial diagnosis, in order to accommodate changes that may occur in children's needs over time, federal guidelines require periodic re-evaluations for all children in special education. An IQ test is often

administered as part of this re-evaluation to determine if the current educational program is meeting the children's needs and if services should be modified or discontinued. At this time, children run the risk of receiving a diagnosis based on a norm that has continued to age since their initial diagnosis, thus obtaining a further inflated score. Therefore, the services provided and the financial costs of providing them to disabled children can vary widely throughout the course of those children's education.

Consequently, the services and resources provided to misdiagnosed children will change independent of their actual cognitive ability and educational needs. In other words, schools will misallocate their financial resources and the students may not receive the services they need. Such findings and implications call into question the use of IQ cut-off scores in special education diagnoses and suggest that researchers, teachers, administrators, and policy makers must recognize the role of the Flynn effect when determining the educational needs of children with disabilities.

MODELING

Modeling describes the process of learning or acquiring new information, skills, or behavior through observation, rather than through direct experience or trial-and-error efforts. Learning is viewed as a function of observation, rather than direct experience (Holland & Kobasigawa, 1980). When viewed as a process of learning, there are three elements involved in modeling: the model, or the person observed, the observer, the individual who acquires new knowledge or skills as a result of observing

the model, and reinforcement, which, in part, determines which behaviors will be repeated. These three factors interact to affect behavior. Reinforcement entails the use of reinforcers (primary or secondary) to increase or decrease the likelihood of future behavior. Through observation of models, a student may learn to hit a baseball (motor skills), how best to interact with members of the opposite sex (social skills), or how to perform double-column addition (intellectual skills). Models can be real people the student observes directly (e.g. teachers, parents, coaches), or they can be symbolic characters in books, movies, and television. In either form, real or symbolic, it is difficult to imagine any society in which modeling has not played a crucial role in the transmission of knowledge, skills, and behaviors from one generation to the next.

MODELING EFFECTS ON LEARNING AND BEHAVIOR

Bandura and Walters (1963) concluded that the observation of models can result in one of three outcomes: (a) the modeling or observational learning effect, (b) the inhibitory or disinhibitory effect, and (c) the eliciting effect (which has also been referred to, by Holland and Kobasigawa, 1980, as the social facilitation or response facilitation effect). The modeling effect refers to the acquiring of new behavior as a result of observing a model, real or abstract. Learning how to hit a baseball can come from watching the coach directly or from watching a famous baseball player demonstrate the skill on a best-selling instructional video. The inhibitory or disinhibitory effect refers to the strengthening or weakening of behaviors as a result of observing a model. Many students will be inhibited about acting out in class simply by observing a classmate being punished for a particular behavior. Conversely, some students will be disinhibited, or will be more likely to act out, when they observe that same behavior not being punished. The eliciting effect occurs when a previously learned behavior happens more frequently as a result of observing a model being reinforced for the same behavior. Although it is similar in nature to the modeling effect and disinhibitory effect, Bandura (1971) suggests that the eliciting effect is unique for a couple of reasons. He notes:

Response facilitation effects can be distinguished from observational learning and disinhibition by the fact that no new responses are acquired, and disinhibitory processes are not involved because the behavior in question is socially sanctioned and, therefore, is unencumbered by restraints. (p. 656)

Advertisers rely on the eliciting effect to sell their products by trying to convince people that purchasing their special brand of product (e.g. jeans, perfume, car), will make them more attractive, sophisticated, or likeable in the eyes of others.

ROLE OF MODEL, OBSERVER, AND REINFORCEMENT

As has been discussed, modeling, or learning as a function of observation, involves the model, the observer, patterns of reinforcement, and how these factors interact to influence behavior or learning. Attributes typically associated with effective models include power, prestige, competence, and warmth or caring. Models that demonstrate one or more of these characteristics are likely to have a stronger influence on the observer (Bandura, 1986). On the part of the observer, in order for modeling to be effective, there are four processes that must take place: attention, retention, reproduction, and motivation. First, the observer must pay attention. People are more likely to pay attention to models in a position of power (e.g., President of the United States) or prestige (e.g., music or movie star), who demonstrate competence (e.g., recognized expert), or show warmth (e.g., a caring teacher) toward the observer. Second, the observer must be able to retain what has been observed by encoding it in long-term memory. Effective teachers incorporate modeling in lesson plans and activities that facilitate long-term learning of information and skills. Third, the observers must be able to reproduce what has been observed. Not only do they need to possess the physical capacity, but they must also believe that they are capable of reproducing the behavior or task. Lastly, the student must be motivated for modeling to be effective. When a student observes other students in the class being reinforced by the teacher for speaking up during a class discussion on World War II, this may motivate the student to overcome his or her shyness and contribute to future class discussions. At the same time, when a teacher ridicules wrong answers from students, other students are less likely to be motivated to speak up for fear of also being ridiculed if they give the wrong answer.

Much in the same way as it functions in operant conditioning, reinforcement (type and frequency) influences the response patterns of observed behavior in the process of modeling. Rather than having a direct influence, however, such as in operant conditioning, reinforcement in modeling has a more indirect role in the learning of new behavior. When individuals observe behavior being punished or rewarded in others, this may lead to the vicarious reinforcement of that behavior in the individual. According to Bandura and Walters (1963), reinforcement in modeling operates in one of four ways, three at the level of the observer, and one at the level of the model. At the level of observer, there is increased likelihood that an observed behavior will be imitated if: (a) the observer is directly reinforced by the model, such as when a teacher praises a student for correctly doing a math problem just demonstrated on the board; (b) the imitated behavior is reinforced by its own consequences, such as a mother's excitement to the

child who says "mommy" for the first time; or (c) the observer experiences vicarious reinforcement, such as the shy student who speaks up more in class after observing the teacher respond positively to other students who have done so. Reinforcement occurs at the level of the model when being imitated becomes reinforcing in itself, such as the father who feels proud because his son's batting performance improves as a result of instruction from the father. The father will be more likely, in this case, to continue with the instruction because the outcome is reinforcing the modeled behavior.

Modeling as a process of learning draws heavily from a variety of theoretical sources, including behaviorism (classical and operant conditioning), social learning and social cognitive theory, information processing theory, and sociocultural theory. In order to understand how characteristics of the model, the observer, and reinforcement interact to affect learning and behavior, it is necessary to understand how the various theories have uniquely contributed to our current understanding of modeling.

MODELING AND EARLY LEARNING THEORY

In early theories of human learning, namely behaviorism (i.e., classical and operant conditioning), theorists such as Ivan Pavlov (1849–1936), John B. Watson (1878–1958), and B.F. Skinner (1904–1990) used animal experiments to search out and verify explanations for human behavior. In classical conditioning, Pavlov discovered that dogs could be conditioned to respond in a certain way through the pairing of different stimuli in the environment. From this perspective, learning was viewed as a stimulus-response (S-R) relationship. A stimulus (in the environment) could be manipulated to elicit a particular response (in the individual). In classical conditioning, the focus is on how involuntary responses, such as salivating, are elicited as a result of changes in environmental conditions. As such, classical conditioning only describes one way that learning can occur in animals and humans, rather than having practical applications for classroom management. It was not until the later work of Skinner, in which he introduced the notion of reinforcement, that learning theory began to have practical implications for the classroom and student learning.

Lefrançois (2000) writes, "Simply put, Skinner's model of operant conditioning describes learning as an increase in the probability of occurrence of an operant (emitted response) as a function of reinforcement" (p. 123). With operant conditioning, Skinner expanded the behaviorist model of learning from (S-R) to include reinforcement, in which learning was viewed as (S)timulus-(R)esponse-(R)einforcement-(R)esponse, in which the increased or decreased likelihood of a behavior was contingent upon the type and frequency of reinforcement used. Types of reinforcement include positive reinforcement, negative reinforcement, and

MODELING IN THE CLASSROOM

To model a Venn diagram for early elementary students, the teacher, Ms. Lopez, first accesses the students' background knowledge. She then models completing a Venn diagram using think alouds.

Ms. Lopez: "Girls and boys, yesterday we talked about how apples and oranges are similar and how they are different. Today I'm going to show you how we can organize that information in a Venn diagram. Raise your hand if you've seen a Venn diagram. [Show a blank Venn diagram.] We can use a Venn diagram to organize information about two items that we are comparing and contrasting. Information that applies to both is written in the area in the middle where the two circles overlap."

On the Elmo, Ms. Lopez draws a Venn diagram: "First, I make sure that my paper has the long sides at the top and bottom. I'll draw a big circle on the right side of the paper. That's where I'll write everything about only apples, so I'll write 'Apples' above that circle. My second circle will be on the left side of the paper, but watch carefully. The second circle is going to overlap the first one and the overlap is big enough for me to write things there. I'll label the left circle 'Oranges' because that's where I'm going to write everything about only oranges. Over the center part, where the two circles overlap, I'll write 'Both.'"

"The first thing I have to do is remember what I know about apples and oranges. I know that apples are red, so I'll write 'red' in the circle labeled 'apples.' Since I wrote about the color of apples, I need to write about the color of oranges across from that in the Venn diagram. I'll

write 'orange' in the circle labeled 'Oranges' directly across from 'red' in the 'Apples' side. We want to keep our comparisons across from each other so we can see them easily when we look at the Venn diagram."

Ms. Lopez finishes writing and looks at the class. "Let me think about what else I know about apples and oranges. I can compare their skin. Apples have skin you can eat, so I'll write 'have skin you can eat' in the 'Apple' side of the Venn diagram. We have to peel oranges and don't eat their skin, so I'll write 'can't eat the skin/peel' in the 'Orange' side."

"I know they're both fruit, so I'll write 'fruit' in the overlapping part under 'Both' because that fact is about both apples and oranges."

Ms. Lopez continues her think aloud, saying, "Let me see. We get juice from both fruits, so I can include that in the section about both," as she continues to fill in the Venn diagram.

"What else do I know about apples and oranges? I know. Oranges have segments and apples are solid fruit, so I'll write 'segments' in the 'Orange' section and 'no segments' in the 'Apple' section."

Ms. Lopez continues entering facts about apples and oranges until the diagram is complete frequently reminding the students that they need to be careful to write in the information that compares things directly across from each other in their sides of the Venn diagram so the information is organized.

Heidi H. Denler

punishment I and II. Frequency of reinforcement refers to schedules of reinforcement, such as continuous or intermittent. Some researchers (e.g., Masia & Chase, 1997) have linked operant conditioning with observational learning by pointing out that reinforcement plays a crucial role in determining the likelihood that an observed behavior will be imitated. Further, Bandura (1977) noted that imitation itself is a class of operants that is strongly influenced by patterns of reinforcement.

MODELING AND SOCIAL LEARNING THEORY

Bandura played a crucial role in bridging the gap between behavioral theory, with its focus on direct experience, and

social learning theory, in which many believed that much of human learning occurred through the process of socialization. Rather than having to be "conditioned" (classical conditioning) or "shaped" (operant conditioning), Bandura and other early social learning theorists posited that the adults in any society transferred the skills and knowledge of that society from one generation to the next through a socialization process. Miller (1983) notes that it was at this point that learning theory moved strictly from the realm of the laboratory and into the real world as a way to explain human learning.

Miller (1983) also notes that two major shifts occurred in the history of social learning theory. First was the early work by Bandura and others demonstrating

Modeling

that imitation was linked with operant conditioning through reinforcement, or, that observed behavior was more likely to be imitated when it was reinforced in some way. This presented a major shift in learning theory because, for the first time, behavior was not viewed as only being a function of direct experience. The second major shift occurred with the work of Bandura and Walters in the 1960s and 1970s in which they argued that observational learning could occur without demonstrating a particular behavior. With behaviorism's focus on observed and measurable behavior, the assumption was that learning only occurred to the extent that it could be measured. Bandura (1965) referred to the latter as "no-trial learning." With these shifts came an increasing focus on how models and observers influenced the learning process, especially in Bandura's 1986 model of reciprocal determinism.

MODELING AND COGNITIVE PROCESSES

As discussed earlier, models can affect behavior in one of three ways, including the modeling effect, the inhibitory or disinhibitory effect, and the eliciting effect. With Bandura's reciprocal determinism model of learning, greater attention was paid to how the individual (observer) played a role in the learning process, especially in how cognitive and motivational processes influenced individual perceptions of observed events. Bandura (1986) notes that the greater the cognitive ability and prior knowledge on the part of the individual, the greater the perceptive ability of what is being observed. According to social cognitive theory, self-efficacy and self-regulation are important processes related to modeling in achievement contexts (i.e. school outcomes). Similarly, information processing theorists have clarified how such processes as encoding, retrieval, long- and short-term memory, and metacognition can also influence observational learning (Schunk & Zimmerman, 1996). In both cases the focus is placed on how observers perceive and process the information they are observing, and to a larger degree how capable they will be in reproducing the observed skill or behavior. Bandura (1986) refers to modeling as an "information-processing activity in which information about the structure of behavior and about environmental events is transformed into symbolic representations that serve as guides for action" (p. 51). Bandura suggests that modeling, on the part of the observer, is governed by four processes: attention, retention, production, motivation (see previous discussion on these processes for further detail).

MODELING SOCIOCULTURAL THEORY

In many ways, Lev Vygotsky's sociocultural theory of intellectual development combines many of the impor-

tant aspects of modeling in a way that illustrates the importance of observation in the process of learning. Vygotsky hypothesized that larger cultural and social systems played an essential role in the acquisition of language skills, intellectual development, and ultimately in becoming literate in the traditions and knowledge of a greater society (John-Steiner & Mahn, 1996). Without actually using the term modeling, Vygotsky described a process of intellectual development that started at the level of observation and eventually moved to the level of internalization. Many students are familiar with terms such as apprentice and the zone of proximal development, where through observation and reinforcement (i.e., scaffolding), students develop ever more sophisticated views of the world. While not using the exact terms, Vygotsky suggested that the tools of any society, which could be viewed as symbolic models, and teachers, who are examples of real-life models, are essential in helping children internalize and integrate skills and knowledge that are first perceived at the level of observation.

MODELING AS A MODE FOR LEARNING

Modeling is one of the most efficient modes of learning of any new skill or knowledge (Bandura, 1986). It is difficult to imagine any society that has not relied on models in one form or another to transmit the most important and basic cultural values, customs and beliefs from one generation to the next. If all of human learning had occurred at the level of direct experience or trial-and-error efforts, human progress would have occurred at a much slower rate. From childhood through adulthood, modeling plays a key role in the acquisition and development of cognitive and metacognitive skills, fine motor skills, interpersonal skills, and later professional skills. Each of these is gained primarily through the process of observation.

Motor skill acquisition and development occur as children observe parents, siblings, and peers interact with their worlds. From the simplest act of learning how to pick up and use a fork to the complex and multifaceted process of driving a car, all of these skills are acquired through the observation of models. Which skills are learned and repeated by the observer will ultimately depend upon the types of reinforcement received, as well as how capable or motivated the observer is to repeat those behaviors.

Learning simple cognitive skills, such as basic arithmetic or reading skills, as well as more complex cognitive skills, such as critical thinking or problem solving, are facilitated when models verbalize their own thought processes as they engage in these activities. Thoughts are thus made observable, and potentially modeled, through overt verbal representation of the model's actions. Modeling

both thoughts and actions has several helpful features that contribute to its effectiveness in producing lasting improvements in cognitive skills. Nonverbal modeling gains and holds attention, which is often difficult to sustain by talk alone. It also provides an informative semantic context within which to imbed verbalized rules. Behavioral referents confer meaning on cognitive abstractions. Moreover, verbalized rules and strategies can be reiterated in variant forms as often as needed to impart a cognitive skill without taxing observers' interest by using different exemplars. In addition, the more and varied application can deepen understanding of generative rules.

According to the social cognitive model of learning, the acquisition of metacognitive and self-regulatory skills and competence first develops through social interaction, otherwise known as observational learning (Schunk & Zimmerman, 1996). Schunk and Zimmerman suggest that in developing what they call self-regulatory competence, students need to be given opportunities to practice the various strategies associated with self-regulated learning in order to fully develop and master this set of skills. Mastering these skills is made easier when models provide "guidance, feedback, and social reinforcement during practice."

MODELING AND COGNITIVE APPRENTICESHIP

Cognitive apprenticeship (Collins, Brown, & Newman, 1989; Collins, Brown, & Holum, 1991) incorporates key aspects of modeling, self-regulation and mastery learning. In cognitive apprenticeship, in which "thinking is made visible," teachers can utilize or combine various methods (i.e., modeling, coaching, scaffolding, articulation, reflection, and exploration) to help students build on their prior knowledge in a way that allows them to become self-regulated learners. Collins and his colleagues (1991) contend that through modeling, coaching, and scaffolding, which they refer to as the "core" of cognitive apprenticeship, students develop and acquire an integrated set of skills through the processes of "observation and guided practice."

Cognitive apprenticeship differs from traditional apprenticeship in three important ways. First, in traditional apprenticeships, the process of learning usually involves easily observable tasks. The carpenter learns his trade by following the example of the more experienced craftsman. There is little difficulty learning the "thinking" behind the successful completion of a particular task or process. In cognitive apprenticeships, the model, perhaps a teacher, has the difficult challenge of "making thinking visible," while usually engaging in an abstract task or process. Further, in cognitive apprenticeships, both the model's and the observer's thinking need to be

made explicit. For the model, this is to ensure that the observer understands the how, why, and when of solving a particular problem. For the observer, this is to ensure that he or she receives proper feedback and support (i.e., scaffolding) during the learning process. Second, in traditional apprenticeships, the process of learning usually occurs in authentic settings while engaging in actual tasks. The learning is situated in a context and presents both the model and the observer the opportunity to engage in and understand not only the final product, but also how the final product is achieved. In a cognitive apprenticeship model, such as learning in the classroom, the process of learning occurs at the abstract level. Learning at the abstract level may lead to difficulty with transfer, or the ability to generalize newly acquired skills and knowledge in future activities.

To enhance learning in a cognitive apprenticeship model, Collins, Brown, and Holum (1991) offer a few suggestions for teachers. First, they suggest that teachers offer students a variety of tasks that range from "systematic to diverse." By presenting a diversity of tasks, teachers challenge students to generalize what they have observed. Second, they encourage teachers to help students reflect on their experiences in ways that help students "articulate the elements that are common across tasks" (p. 41). Lastly, they suggest helping students to understand the relevance of what they learn in order to motivate them to utilize newly acquired skills and knowledge in future endeavors. Clearly, the cognitive apprenticeship model requires that both the model and observer be active members of the learning process.

Models and modeling play an essential role in observational learning. At its core, modeling refers to imitation as a function of observation; however, it is much more than simple mimicry (Bandura, 1986). As a process of learning, modeling draws from various theoretical perspectives, including behaviorism (classical and operant conditioning), social learning and social cognitive theory, sociocultural theory, and information processing theory to explain how the model, the observer, and patterns of reinforcement interact to affect learning and behavior. Contrary to earlier views of learning, modeling assumes that individuals can learn vicariously through the experiences of others. In addition, learning is assumed to occur even in the absence of a direct demonstration of a particular learned skill or behavior. It may simply be a matter of choice on the part of the individual not to perform the newly acquired skill. Models can be either real or abstract, and have been shown to influence behavior in one of three ways: (a) the observational learning or modeling effect, (b) the inhibitory or disinhibitory effect, and (c) the eliciting effect. In order for modeling to be effective, the observer must be able to attend to, retain,

reproduce, and be motivated to perform the observed behavior.

Contemporary views of modeling have linked this process of learning with the acquisition of fine and basic motor skills, interpersonal skills, cognitive development, and metacognition and self-regulation. Most contemporary views link aspects of the model, the observer, and reinforcement in a way as to explain new and effective ways of learning. One example of this would be cognitive apprenticeship (Collins et al., 1991), in which teachers, as effective models, make their thinking explicit to help student growth and development. As Schunk and Zimmerman (1996) have noted, when models also provide assistance and guided practice, student learning is enhanced.

Christian E. Mueller

MORAL DEVELOPMENT

Morality refers to a doctrine or system of beliefs, values, or principles that govern human conduct in two ways: by prescribing positive behaviors that benefit others and by proscribing negative actions that harm others. The former set of behaviors, often called prosocial behaviors, include sharing, helping, and comforting. In terms of moral judgment, these actions are viewed as good and ought to be carried out. The latter type of actions, often referred to as inhibitory or negative morality, include violations of others' rights and welfare, such as hitting, harming, and otherwise injuring others physically or psychologically, actions viewed as bad which one ought not to do.

While defining morality might be a fairly straightforward matter, speculations about its origins and development have proved far more contentious. So, too, has the role of schools and classroom teachers in promoting its growth. This entry offers a summary of the major differing views on the origins of morality and its development. It focuses on two forms of moral development judgment and identity that have generated decades of empirical research and have affected moral/character education in the United States. In the context of describing the normative developmental changes that occur from early childhood through late adolescence, the entry explores the roles of gender, ethnicity, and culture on moral development. The role schools and teachers in fostering moral development is considered next, with a set of recommendations for educators.

MORAL DEVELOPMENT: SUMMARY OF PSYCHOLOGICAL PERSPECTIVES

In the field of psychology, morality and its development has been variously defined by different types of psychologists. Psychoanalysts, such as Sigmund Freud (1856–1939), believe that morality is rooted in the avoidance of guilt and shame and that its development is a product of the super-ego. In a similar vein, some developmental and social psychologists, such as Martin Hoffman and Jonathan Haidt, respectively, point to emotions as the basis of morality. According to Hoffman, as well as evolutionary psychologists, the origins of these moral emotions or senses date back many millennia to what has been

called the ancestral environment or environment of evolutionary adaptation. While modern speculation about the biological and evolutionary basis of morality dates back to Charles Darwin's *The Descent of Man*, it has experienced a resurgence in the 21st century as findings from neuroscience have emerged.

Behavioral psychologists, most famously B. F. Skinner (1904–1990), offer a starkly contrasting view of the origins and development of morality regarding the mind of the newborn as a so-called blank slate, devoid of any inherent moral emotions or inclinations whatsoever. Direct experiences and the consequences they beget are the sole sources of all learning, moral and otherwise. In short, moral values are essentially synonymous with cultural mores. Morality has no biological or evolutionary basis, nor is it motivated by emotions, conscience, or judgment; it is simply those behaviors reinforced as good or bad, driven by the rewards they beget or the punishments they offset.

Despite the historic importance and one-time ascendancy of the foregoing views, the work of cognitively oriented developmental psychologists has dominated the field of moral psychology since the 1960s. Rooted in seminal work on moral judgment by Jean Piaget (1896–1980), Lawrence Kohlberg (1969) created a three-level, six-stage cognitive-structural model of the growth in moral reasoning and judgment. Like emotion-based theories, cognitive-structuralism posits that biology is important to moral development (though in terms of maturation of cognitive capacities, not the possession of inherent emotions). Like behavioral views, cognitive-structuralism posits that the environment plays a critical role in moral learning (though through thoughtful discussions of moral dilemmas, not mindless associations between behaviors and reinforcers). Given the enormous influence of Kohlberg's work on the field of moral psychology and education, his theory is described in more detail below. Before doing so, a brief discussion follows below of the important view of moral development that developed since about the 1980s.

While Kohlberg's theory and research continued to influence the field, the last quarter of the 20th century witnessed the gradual rise of empirical and theoretical work on the development of moral self-understanding and identity. The interest in moral identity and its role in moral behavior was brought into focus with Augusto Blasi's 1980 review of empirical research on moral cognition and moral action. After describing the relatively modest relations between moral judgment and moral behavior, Blasi posited that the observed gap might be explained by moral identity or the extent to which moral values and goals are regarded as core or essential aspects of the self. Individuals with strong or well developed

sense of the self-as-moral would be more likely to act in accordance with their moral judgments. The critical mechanism is a sense of personal responsibility to act and the concomitant need to maintain "self-consistency" (Blasi, 1983). Blasi's groundbreaking work on moral identity spawned much theoretical and empirical research, which is explored below.

MORAL JUDGMENT DEVELOPMENT: KOHLBERG'S COGNITIVE STRUCTURAL MODEL

Based on his longitudinal study of 75 males as well as numerous cross-cultural studies in disparate countries (e.g., Canada, Mexico, Taiwan, Turkey), Kohlberg posited that moral judgment develops along a three-level, six-stage continuum. Each of the three levels is composed of two stages, which describe the structure of thinking individuals use as they reason through a moral dilemma. The Moral Judgment of Interview (MJI) consists of five moral dilemmas (i.e., paragraph-length hypothetical vignettes in which the protagonist faces a decision that pits two moral values against each other). In the classic Heinz and the Drug dilemma, for example, issues of life and property rights are put at odds, and one must decide whether the Heinz should steal a drug that might save the life of his wife. However, it is not the determined course of action itself (steal/do not steal) that is used to score one's level and stage moral judgment. Rather, it is reasoning that one employs to render the decision that is of greatest interests to cognitive-structural theorists such as Kohlberg.

The first or preconventional level of development is characterized by largely egocentric reasoning, where good or right actions are defined in terms of their consequences to the self. At stage one, the first and most primitive form of reasoning, there is an unquestioning deference to superior power (e.g., "might makes right") and the physical consequences of action (regardless of meaning or value) dictate whether it is good or bad. At stage two, right action consists of that which instrumentally satisfies one's own needs and the needs of others. While elements of fairness and reciprocity are present, they are construed in a physical, pragmatic manner (e.g., "you scratch my back and I'll scratch yours") and not in terms of justice. Empirical research suggests that these two stages of reasoning are typical of children aged 4 through 10.

The second or conventional level of development morality is seen as conforming to and even maintaining the expectations, rules, and norms of the one's family, group, or society.

Kohlberg referred to stage three as "good-boy-good-girl orientation" because of its emphasis on pleasing others by conforming to stereotypical images of various

social roles (e.g., being a “good son” by helping your mother with chores or a “good husband” by sacrificing your own safety for that of your wife). At stage four a higher level of abstraction is achieved and employed in moral reasoning. Rather than conforming to familial roles and expectations, the emphasis is now on maintaining law and order. Right behavior consists of doing one’s duty, showing respect for authority and maintaining the given social systems (e.g., legal, religious). Empirical research suggests that these two stages of reasoning are typical during late childhood (Stage Three) and adolescence (Stage Four).

Finally, the fifth or postconventional level of development is characterized by a significant shift from given norms and conventions toward autonomous moral principles and values. At stage five, a “social-contract orientation” is achieved, and right action is defined in terms of general rights and standards. While still possessing legalistic overtones, reasoning at this stage involves a clear awareness of the relativism of personal values and opinions. Accordingly, an emphasis is placed upon procedural rules for reaching consensus and the possibility of changing the law (not simply conforming to it) to maximize social utility. At stage six, moral development reaches its pinnacle, and reasoning is characterized by consideration of universal moral principles. Prominent among these principles is respect for life and the notion of that all humans regardless of class, color, and creed possess an inherent dignity and worth that cannot be bought or bartered. Empirical research suggests that relatively few people achieve stage five reasoning and fewer still stage six. Indeed, stage six was all but removed from the model in the later 1980s because so few people demonstrated such thinking, and it is not included in the definitive scoring manual for the MJI (Anne Colby & Kohlberg, 1987).

CRITICISMS AND CORRECTIVES TO KOHLBERG AND COGNITIVE STRUCTURALISM

As with any theory, Kohlberg’s model of moral development is not without shortcomings and vocal critiques. Three of these are discussed below.

Gender Bias. Perhaps the most famous criticism of Kohlberg’s theory was launched from within his own research group at Harvard University. In the late 1970s Carol Gilligan began to raise concerns about gender bias in the theory, suggesting that justice-based philosophical orientation of the model emphasized traditional masculine values and traits (e.g., individual rights, rationality, and impartiality) and thus marginalized traditional feminine values and traits (e.g., interpersonal care, intuition,

and social relations). Her book, *In a Different Voice*, which offered an alternative stage model of care-based moral development, was widely read, if not fully embraced. This and other prominent books on caring inspired numerous empirical investigations into the question of gender differences in moral orientation and judgment. These investigations lend some credence to Gilligan’s critique but taken together show that gender differences are not as great as she claims (e.g., Walker, 2006). Where, for example, Gilligan posits a dichotomy—males are justice oriented and females are care oriented—the research indicated that males and females possess both justice- and care-based orientations (with females being only slightly more care oriented). With regard to moral reasoning itself, the vast majority (86%) of the 80 MJI studies reviewed by Walker revealed no such differences. Nonetheless, Gilligan’s critique was an important one that pushed the field of moral psychology beyond its philosophical moorings in formal ethics and liberal social science.

Cultural Differences. A second and equally heated debate that Kohlberg’s theory generated concerns his claims of universality; that is, that people the world over from tribal nomads to inner-city urbanites undergo the same six-stage developmental progression in their capacity to reason morally. In the most comprehensive review of this claim, involving 45 cross-cultural studies using the MJI, John Snarey reported general support for it but with a few major caveats. Chief among these is a bias favoring complex urban societies and middle-class populations (i.e., both score slightly higher). Similarly, cross-cultural studies employing the Defining Issues Test (i.e., a widely used pen and paper adaptation of the MJI) have shown educational attainment to be the single best predictor of moral reasoning scores. Age, gender, and ethnicity explain relatively little variance (if any at all) once education is accounted for.

It is important to keep in mind Kohlberg’s model and these empirical studies focus on only one component of moral functioning: the development of moral judgment. Even if people across the globe exhibit the same invariant cognitive-developmental progression in their capacity to reason through a set of standardized hypothetical dilemmas, there remains plenty of room for cultural variation in the content, prioritizing, commitment to and expression of moral values and judgments. The work of cultural psychologists such as Richard Schweder and Hazel Markus provides great insights into some of these differences. So, too, does the work social-cognitive domain theorists such as Elliot Turiel, Larry Nucci, and Judith Smetana. They point to distinctions between three domains of judgment: the personal, social conventional, and moral. In doing so, domain theorists distinguish cultural mores from moral principles and identify where they may

overlap and conflict. Furthermore, domain theorists believe that each domain has its own developmental trajectory. This conjecture is meant to serve as a corrective to Kohlberg's model, which is seen as conflating the personal and conventional with the moral.

The Thought/Action Problem. Perhaps that most enduring and damning shortcoming of Kohlberg's theory relates to his claim that moral judgment "can be a quite powerful and meaningful predictor of action" (Kohlberg & Candee, 1984, p. 397). As noted above, Blasi's 1980 review of the literature investigating the relations between moral reasoning and moral action suggested otherwise. This finding was not news to philosophers who had long since been writing about the thought/action problem. And, of course, most people need only look at their histories to find examples of behavioral engagement at odds with moral judgment. In educational settings, the epidemic of academic cheating offers a disconcerting illustration of the phenomenon: Most students cheat, even if they believe it is wrong or unjustifiable to do so. In short, while judgment may be a necessary component of moral action, it alone is not sufficient to compel it. Blasi's review made this clear and in doing so ushered in a new era of theorizing and research on moral motivation, one focusing on moral self, identity, personality, and character.

MORAL IDENTITY: BLASI'S SELF MODEL AND ITS LEGACY

It is important to note at the outset that despite the theory's limitations in predicting behavior, Blasi does not seek to rid moral psychology of its interest in moral judgment. He recognizes its importance, regarding it as necessary but insufficient in explaining the complexity of human moral motivation and functioning. In particular, the movement (or lack thereof) from thought to action needs further explanation, and Blasi's self model offers one. Rooted in the work of Eric Erikson (1902–1994) and Jane Loevinger (1918–2008), Blasi posits that the observed gap might be explained by moral identity, that is, the extent to which one regards moral values and goals as core or essential aspects of the self, "those aspects without which the individual would see himself or herself to be radically different" (Blasi, 1984, p. 131). Individuals with strong or well-developed sense of the self-as-moral are more likely to act in accord with their moral judgments. The critical mechanism is a sense of personal responsibility to act and the concomitant need to maintain self-consistency.

Blasi's self model also suggests that moral identity is not a unitary construct. Whereas some individuals may

see honesty and fairness as essential aspects of themselves, other individuals may highlight compassion and caring for others as most salient to their sense of self-as-moral. In *Varieties of Moral Personality*, philosopher Owen Flanagan (1991) echoes Blasi's conjecture, arguing that "ethical goodness is realized in a multiplicity of ways" (p. 332). Lawrence Walker and his colleagues conducted several studies of moral maturity and exemplarity, focusing on three types: just, brave, and caring (see Walker, 2004). Research on moral identity has extended into domains beyond, but related to, the moral domain. Jim Younnis and Miraday Yates's work on civic identity provides a good example.

Finally, Blasi contends that moral identity is developmental in nature, that how the "essential self" is perceived and defined changes over time. Moreover, the centrality of morality to the self varies between individuals; the self comprises many qualities and their hierarchical ordering varies from person to person. In their seminal work on the development of self-understanding through childhood and adolescence, Damon and Hart found that moral qualities such as honesty and loyalty did not become a part of study participants' self-definitions until they reached adolescence. In the twenty years since Damon and Hart's 1988 book *Self-understanding in Childhood and Adolescence* was published, very little progress was made in creating a model of moral identity development comparable to Kohlberg's model of moral judgment development. It is clear that just as very few people ever achieve stage six reasoning ability, very few experience a full integration of morality and self. In their landmark 1992 study *Some Do Care: Contemporary Lives of Moral Commitment*, Anne Colby and William Damon give insights into the lives of people with extraordinary commitment to moral causes and actions. For these exceptional individuals, morality has been so completely integrated into their sense of self that they report feeling as though they had no choice. Though in a different way, this sense of not choosing but rather acting automatically is at the heart of the connections between moral expertise and schema accessibility that Daniel Lapsley and Darcia Narvaez (2004) make in their social-cognitive approach to moral development.

MORAL EDUCATION: INTEGRATIVE ETHICAL EDUCATION AND OTHER APPROACHES

Most Americans embrace the idea that public school curricula include some form of moral or character education. Indeed, the moral and civic purposes of education have a long history in both Western and Eastern political thought. The content and form as well as demand for moral education has varied greatly over time, even within

the brief history of U.S. democracy (see Colby et al., 2003). This does not mean moral education is without its detractors or that there is no lively debate about the “what” and “how” of moral teaching and learning. Nonetheless, in the early 2000s there was increasing concessions and convergence among once divergent camps in the field. Traditional character educators, whose chief objective was the inculcation for moral virtues such as honesty and chastity, have now conceded that moral reasoning has a place in the curriculum. Meanwhile, cognitive-developmentalists such as Kohlberg have realized the motivational value of character traits.

This transformation and its history are beyond the scope of this entry, but interested readers should consult William Damon’s 2002 *Bringing in a New Era of Character Education* and Daniel Lapsley and Clark Power’s 2005 *Character Psychology and Character Education*. In addition, Larry Nucci’s 2002 *Education in the Moral Domain* and Nel Noddings’s 2002 *Educating Moral People: A Caring Alternative to Character Education* are excellent resources for classroom teachers as they strike a balance between theory and practice. Rheta DeVries and Betty Zan’s 1994 *Moral Children: Constructing a Constructivist Atmosphere in Early Education* remains a long-standing and oft-cited guide for educators.

From these books and numerous other resources, the following sampling of recommendations for classroom practices rooted in Darcia Narveaz’s 2006 “Integrative Ethical Education” (IEE). As the name suggests, IEE explicitly brings together traditional character education and cognitive-developmental approaches. It is also rooted in the four component model of moral functioning (Rest, 1986), which highlights the need to foster growth in students’ moral 1) sensitivity, 2) judgment, 3) motivation, and 4) action.

Moral Sensitivity. According to Rest, moral sensitivity is the first component of moral functioning. While psychoanalysts, emotion-based theorists, evolutionary psychologists, and domain theorists all contend that some degree of moral emotional awareness and sensitivity is bred in the bone, all would also agree that the social environment and education are important in turning on and tuning in moral emotions and sensitivity. Teachers seeking to foster students’ moral sensitivity should create learning environments and curricula that offer frequent exposure to moral emotions, virtues, concepts, and issues; they should help students take the perspective of others (e.g., classmates, historical figures, contemporary politicians), and they should call attention to examples of caring and justice as well as insensitivity and injustice, including bias, sexism, and racism. In doing so, teachers can help students identify moral emotions and issues and express and manage them.

Moral Judgment. Firmly rooted in Kohlberg’s cognitive-structuralist model, this component of functioning concerns the capacity to interpret complex moral dilemmas. Whether real or hypothetical, moral dilemmas require people to discern the competing interests and values at stake and to render a judgment that—depending on the nature of the dilemma—gives due weight to one’s own well-being, concern for others, respect for law and tradition, and principles of justice. To foster these capacities educators should engage students in dilemma discussions. Doing so effectively, however, is not easy.

Moral Motivation. This component has been relabeled numerous times in the literature (motivation, commitment, and focus) as it is probably the broadest of the four. After all, the motivation to act or not to do so is a multifaceted phenomenon contingent on both personal and environmental factors. As described above, one of the most important personal factors is moral identity. Students who see themselves as moral beings are more likely to act like moral beings. Teachers can foster students’ moral identity development by exposing them to moral exemplars (e.g., honest, brave, caring) and by creating opportunities for students’ to clarify and cultivate the meaning and importance of moral values and goals in their lives. Moral motivation and identity are also strengthened when educators create school and classroom cultures in which making the right choice and being a good citizen in the community are recognized and rewarded.

Moral Action. The final component of moral functioning is moral action. Even if students possess the necessary sensitivity, judgment, and motivation to act rightly, they may not possess the needed skills or know-how to do so. Resolving conflicts with others, challenging bias and racism when they occur, and taking the initiative to start or even lead good works are not easy tasks. Educators must teach these skills by creating authentic opportunities for students to practice and hone them. Community service projects and school-based organizations offer venues for such skill development. Teachers should both encourage and mentor students’ efforts to address social, moral, civic, and political issues that affect them and their communities.

Moral learning in classrooms does not only occur through formal curriculum or extra-curricular programming. The “hidden curriculum” of schooling, as Philip Jackson famously called it, consists of (often unexamined) norms and policies that collectively give form and meaning to a wide range of behaviors. School governance structures, disciplinary procedures, the allocation of rewards, norms of teacher-student interaction, all communicate morally laden values. Issues of fairness, due process, equal opportunity, respect for differences, and

equity in the distribution of scarce resources and rewards (such as teacher attention and grades) permeate the institution of public education. These factors should not be ignored. Teachers must be mindful of the rules, procedures, and norms they establish in their classroom, and they must be mindful of how they go about following them. When possible, students should be included in the process of establishing the governance structures and disciplinary procedures of their school and classroom communities; they should be given a voice in the process and on-going responsibility for ensuring that the place in which they live and learn is fair, just, and caring.

MORAL EDUCATION

Every society is concerned about fostering moral character in children and forming responsible citizens. Controversy often accompanies these interests because adults do not always agree about what moral character is or how to cultivate it. Does a person with moral character support societal traditions, much like a tribal leader does, or

challenge them, as did Jesus and Martin Luther King Jr.? What exactly do children need to learn in order to be engaged citizens? Further, do children develop moral character through exhortation or through lived experience? Questions like these are debated.

The debate over defining moral education is often pitched between two seemingly opposed perspectives: traditional character education, focused on the development of specific kinds of virtuous traits and habits (Narvaez, 2006) and rational moral education, which focuses on moral judgment and reasoning regarding justice and fairness. The integrative ethical education model (IEE) described below embraces both traditions. IEE defines moral education as the development of moral expertise, which requires both virtue, as intuitions and skills, and moral cognition, as reasoning, imagination, and understanding.

HISTORY OF MORAL EDUCATION

The practices of contemporary moral character education can be traced to ancient Greek philosophers such as Socrates, Plato, and Aristotle (Lapsley & Narvaez, 2006; Nucci & Narvaez, in press). The Socratic emphasis on virtue emphasized the mind, particularly philosophical thinking and reasoning. Socrates’s own pedagogy known as the Socratic method used successive questions to guide students from ignorance to understanding. Knowing what is good was considered the sufficient condition for individuals to be considered good and virtuous. The Socratic emphasis on right thinking and reasoning echoes throughout the philosophy of his student, Plato, in his *The Republic* in which Plato seeks to define justice.

Aristotle’s teachings and philosophy emphasized the practice of good actions, not only reason, as a means to living a life of virtue. With the tutelage of mentors and moral exemplars, Aristotle came to believe that the virtuous life is attainable through the practice of specific habits and virtues. Aristotle’s philosophy of virtue laid the foundation for contemporary paradigms of character education.

The moral philosophy of early Greek thinkers, coupled with Christian theology, morality, and practice, provided a social and educational foundation in European and American societies from the Middle Ages to modern times. The intersection of moral philosophy and religion was especially evident in colonial U.S. schools; indeed, in the eighteenth and nineteenth centuries, U.S. schools aimed to develop students with good character through reading Bible stories and exhortations, what is considered traditional character education.

In the twentieth century, the explicit Protestant Christian theology of education became less congruous with the religious identity of many new immigrant citizens. Teachers could no longer rely on the assumption of a single universal religious identity as the foundation of

moral formation. At the same time, theoretical and empirical challenges were levied against moral character education in general. Among many provocative findings, the early work of Hartshorne and May, in *Studies in the Nature of Character* (1928 1930), concluded pessimistically that little if any universality or transfer of character existed across situations and general incongruence was demonstrated between moral knowledge and moral action.

Empirical challenges to moral character education and a changing social landscape precipitated a general decline in the interest and application of traditional character education in schools in the mid-twentieth century. The study of moral character education in many ways shifted to the psychological arena as issues of personality or values. Values clarification became a way for educators to discuss values without advocating any one in particular.

In the widespread move against behaviorism in psychology, Lawrence Kohlberg brought the developmental work of Swiss psychologist, Jean Piaget (1896 1980), to the United States. Inspired by Piaget, Kohlberg (1984) spawned the cognitive development approach to moral education as a counterweight to traditional character education and its collection of virtues. Kohlberg was concerned about the conventional condemnation of people such as Martin Luther King Jr., who were viewed as common criminals breaking the law. Kohlberg saw that civil rights demonstrators had a higher moral purpose in breaking the law, but he wondered how to prove that was true.

Kohlberg examined the moral development of a cohort of boys through childhood and adolescence. Looking for underlying patterns, he presented his subjects with moral dilemmas and perceived a three-level, six-stage progression in their thinking over time, moving from pre-conventional thinking to conventional to post-conventional (Preconventional level: 1. avoid punishment, 2. Prudence and Simple Exchange; Conventional level: 3. Interpersonal Harmony and Concordance, 4. law and order; Postconventional level: 5. social contract, and 6. universal moral principles). Kohlberg proposed that with age and experience, each person moves from simple to more complex notions of moral reasoning, some moving farther up the stages than others. Each stage is more adequate than the previous one to solve complex moral problems. Kohlberg's basic theory was validated around the world, although there is some controversy about the nature and universality of the higher stages.

In order to stimulate moral reasoning development beyond that promoted by everyday experience, Kohlberg and his students developed the dilemma discussion method. The classic example is the "Heinz Dilemma" in which Heinz, a man of modest means, cannot afford the costly cure for his dying wife. Unable to appeal to the druggist or secure the necessary funds, Heinz breaks into the pharmacy and takes the medicine to save his wife. After the dilemma is presented, students take a position on whether he should steal the drug, and then they participate in small and large group discussions about the reasons for one action or another.

In his later years, Kohlberg and colleagues (Power, Higgins & Kohlberg, 1989) focused on a true-to-life cognitive developmental method, the just community, modeled on some features of the Jewish kibbutz. Implemented in schools and prisons, emphasis was placed upon developing adolescents' ties to community expectations (concerns of Stages 3 and 4) through democratic decision making of community rules (concern of Stage 5). Although an extremely demanding method, the "just community school" approach leads to increased trust, obedience, and loyalty among students, as well as moral stage growth.

NEWER APPROACHES

Newer generations of empirically derived approaches to moral character development developed in the late 20th century. Three are briefly described.

Child Development Project. The Child Development Project (CDP) was founded in the late 1970s as a comprehensive, systems-based approach for fostering positive and pro-social development of elementary-aged children. The CDP focuses on the home and classroom community as the formative contexts for moral character develop-

ment. Similar to Kohlberg's just community model, the intentional democratic structure of the CDP classroom promotes a sense of belonging, cooperation among peers, and sharing of values. A core theoretical component of the CDP is that participatory membership in a caring community, engagement in trusting interpersonal relationships, and collaborative learning experiences provide the necessary curricular and pedagogical foundation for pro-social development.

Teachers and parents become models and guides for the students, provide scaffolding for complex activities and concepts, and support students in their collaboration with peers and development of pro-social skills. CDP curricular materials engage the cognitive, behavioral, and affective components of pro-social development through supportive relationships with an adult, positive interactions with peers, experiences of perspective taking, understanding of values, and discussion of moral issues (see the Web site maintained by the Developmental Studies Center).

Students who participated in CDP demonstrated increased pro-social behavior, increased sense of school community, improved self-concept, and other positive outcomes (e.g., Battistich, Solomon, Watson, & Schaps, 1997). Most notable among the many positive findings was that sense of community was positively related to several key variables of interest such as conflict resolution skills, academic engagement, and concern for others.

Building Assets. It is widely accepted that parents are the primary moral educators of their children. Moral education and formation is more robust, however, when the moral instruction of the parents and family structure are resonant throughout the community (e.g., school, business, media). The Search Institute is a non-profit organization that promotes community-based positive youth development by deepening relationships and asset building. A list of forty positive assets (e.g., family support, adult role models, caring, peaceful conflict resolution) represent the internal and external values and competencies needed for healthy development and fundamental moral education (see the Web site maintained by the Search Institute). Greater numbers of assets are related to fewer risk behaviors. Through Search Institute programs, young people work with peers and adults in the community to deepen relationships, affirm the positive development of youth, and create and uphold institutions that promote an environment and experience that support positive and moral growth. This model has been linked with positive cognitive, affective, and behavioral change such as increased moral action in diverse contexts and communities (Benson, Leffert, Scales, & Blyth, 1998).

Social and Emotional Learning. Moral education occurs across diverse contexts (e.g., home, school, work) and through a variety of methods (e.g., direct instruction, experiential learning, counter-examples). But what are the underlying requisite skills for successful engagement in these moral contexts and activities? Social and emotional learning (SEL) is a theoretical and empirical domain that accentuates emotional intelligence as a suite of necessary skills for successful development. The SEL framework affirms the primacy of parents as moral educators and the importance of asset building within the community for successful development but focuses on specific social and emotional skills for life success. The Collaborative for Academic, Social, and Emotional Learning (CASEL) was founded in the 1990s to further explore how academic achievement skills are related to skills necessary for succeeding in life, both the private sphere of family and the public one of work. When children are emotionally and socially competent (e.g., self aware, respectful of others, able to manage conflict) they are better prepared to make moral and ethical decisions, to engage the moral messages of the community and to build assets from them (Lemerise & Arsenio, 2000). Emotional competencies provide the necessary intrapersonal and interpersonal foundation for successful moral judgment and action. Additionally, when SEL skills are taught in schools, students demonstrate increased engagement with learning and academic achievement.

Integrative Approaches. In the 1990s and early 2000s, there was a renewed interest in reconciling the divergence between traditional character education and rational moral education. Tom Lickona has collected the best concrete ideas and put them together in user-friendly books for elementary teachers. For example, Lickona and Davidson (2006) developed a model for helping high school students to develop both performance character and moral character.

The Integrative Ethical Education model (IEE; Narvaez, 2006) provides a broad, research-based framework for moral character development. It outlines an intentional, holistic, comprehensive, empirically derived approach to moral character education. Rooted in what was intuited by ancient philosophers and confirmed by modern science regarding how to cultivate human flourishing, this approach suggests five steps for educators to follow.

Step 1: Establish a caring relationship with each student. One of the most important protective factors against poor outcomes for a child are caring relationships, first, with an adult in the family, second, with an adult outside the family (Masten & Coatsworth, 1998). Teachers can provide the one relationship that supports a child.

Step 2: Establish a climate supportive of achievement and ethical character. A positive climate meets the needs of the child and fosters a sense of belonging to the larger group (Baumeister & Leary, 1995). Prosocial behavior is nurtured in climates that foster flourishing and the “developmental assets” that support resiliency (Benson et al., 1998). A caring classroom (and school) climate with high expectations is related both to high achievement and to moral behavior (Zins et al., 2004). In a caring classroom, discipline is not punishment but is coached character development.

Step 3: Teach ethical skills across the curriculum and extra-curriculum using a novice-to-expert pedagogy. The four component model (Narvaez & Rest, 1995) provides a functional view of moral behavior. Skills for each of the four components (ethical sensitivity, judgment, focus, action) have been identified. Best practice instruction provides opportunities for students to develop more accurate and better organized representations and the procedural skills required to use them. Children must experience an expert-in-training pedagogy for each skill that they learn. Teachers can set up instruction to help students develop appropriate knowledge by designing lessons according to the following four levels of activities: (1) immersion in examples and opportunities; (2) attention to facts and skills; (3) practice procedures; (4) integration of knowledge and procedures.

Step 4: Foster student self-authorship and self-regulation. Individuals can be coached not only in skills and expertise but in domain-specific self-efficacy and self-regulation (Zimmerman, Bonner, & Kovach, 2002). The most successful students learn to monitor the effectiveness of the strategies they use to solve problems and, when necessary, alter their strategies for success. Students can learn the metacognitive skills that moral experts have, for example, self-monitoring of attention away from temptations, self-cheerleading when energy flags, and selecting or designing the environment to maximize goal completion.

Step 5: Restore the village through asset-building communities and coordinated developmental systems. Truly democratic ethical education empowers all involved—educators, community members, and students—as they form a learning community together, developing ethical skills and self-regulation for both individual and community actualization. The purpose of ethical behavior is to live a good life in the community. Together, community members work out basic questions

such as the following: How should we get along in our community? How do we build up our community? How do we help one another flourish? Each individual lives within an active ecological context in which, ideally, the entire community builds ethical skills together.

The debate over what constitutes moral character education and the proper formation of good citizens continues in the 2000s. Three main categories or genres have emerged as approaches: traditionalist, humanist, and integrationist. The traditionalist genre is characterized by its focus on the development of specific kinds of virtuous traits or habits. Contemporary traditionalist perspectives often focus on a subset of virtues (e.g., Character Counts!). The humanist genre is characterized by the work of the philosophers John Dewey (1859–1952) and Nel Noddings (b. 1929), which focused on the role of experiences and, in particular, the quality of relationships in education and moral character development. Their work is typified by classrooms as democratic, participatory, and caring environments wherein students engage in collaborative endeavors. Finally, integrationists, as the name implies, incorporate traditional character education and rational moral judgment within the context of caring relationships and a caring community. Rational moral education is differentiated from traditional character education by its focus on moral judgment and reasoning oriented toward justice and fairness. Whereas traditional character education is concerned with the explicit formation of specific kinds of character (specific habits), rational moral judgment is concerned with developing the intellectual tools for moral reasoning and judgment. Although these two schools of moral education have been cast as divergent and mutually exclusive, integrative models of moral character education incorporate traditional virtue ethics and moral reasoning exercises within a caring environment for a truly comprehensive model of moral character education (Narvaez, 2006).

MULTICULTURAL EDUCATION

Multicultural education encompasses theories and practices that strive to promote equitable access and rigorous academic achievement for students from all diverse groups, so that they can work toward social change. As a process of educational reform in PK-12 schools, higher education, and increasingly in out-of-school contexts, multicultural education challenges oppression and bias of all forms, and acknowledges and affirms the multiple identities that students bring to their learning.

Scholars have provided a range of definitions of multicultural education since the late years of the civil rights movement. A common theme that researchers of multicultural education underscore is that to maintain its critical analysis of power, multicultural education must be constructed within its history and roots in the civil rights movement (Banks 2004; Grant, Elsbree & Fondrie, 2004; Gay, 2004; Nieto & Bode, 2008; Sleeter & Bernal, 2004). To construct an analysis of power within school

reform, several multicultural educators have defined multicultural education as a matrix of practices and concepts rather than a singular static notion. Three major definitions of multicultural educations are reviewed below.

BANKS'S FIVE DIMENSIONS OF MULTICULTURAL EDUCATION

James A. Banks (1979), a leading scholar in the field, argued in the early development of the field of multicultural education that "educators should carefully define concepts such as multiethnic and multicultural education and delineate the boundaries implied by these concepts" (p. 237). His later work continued to emphasize this point (2006). Banks has historically advanced a definition of multicultural education as a broad concept and extrapolated on five dimensions (1991, 2004, 2006). He formulated the five specific dimensions as *content integration*, *knowledge construction process*, *prejudice reduction*, *equity pedagogy*, and *empowering school culture and social structure* (2004).

Content integration deals with the infusion of various cultures, ethnicities, and other identities to be represented in the curriculum. The *knowledge construction process* involves students in critiquing the social positioning of groups through the ways that knowledge is presented, for example in scientific racism or the Eurocentric view of the "discovery" of America. *Prejudice reduction* describes lessons and activities that teachers implement to assert positive images of ethnic groups and to improve intergroup relations. *Equity pedagogy* concerns modifying teaching styles and approaches with the intent of facilitating academic achievement for all students. *Empowering school culture* describes the examination of the school culture and organization by all members of school staff with the intent to restructure institutional practices to create access for all groups (Banks, 2004). While highlighting the interrelatedness of the five dimensions Banks promotes deliberate attention to each.

NIETO'S SEVEN CHARACTERISTICS OF MULTICULTURAL EDUCATION

Another leading scholar, Sonia Nieto, offered a definition of multicultural education in 1992 that continues to influence discourse in the field (Nieto, 1992, Nieto & Bode, 2008). Nieto's definition of the characteristics of "multicultural education in a sociopolitical context" addresses the context of communities, and the process of education, in terms of elasticity rather than as a fixed and static form (2008, p. 7). She focuses on seven characteristics of multicultural education: "*antiracist*, *basic*, *important for all students*, *pervasive*, *education for social justice*, *a process* and *critical pedagogy*" (Nieto & Bode, 2008, p. 44).

Antiracist education makes antidiscrimination explicit in the curriculum and teaches students the skills to combat racism and other forms of oppression. *Basic education* advances the basic right of all students to engage in core academics and arts; it addresses the urgent need for students to develop social and intellectual skills to expand understanding in a diverse society. That multicultural education is *important for all students* challenges the commonly held misunderstanding that it is only for students of color, multilingual students, or special interest groups. Rather, all students deserve and need an education that is inclusive and rigorous. The *pervasive* nature of multicultural education emphasizes an approach that permeates the entire educational experience, including school climate, physical environment, curriculum, and relationships. In education for *social justice* teachers and students put their learning into action. Students learn that they have the power to make change as apprentices in a democratic society. Multicultural education as a *process* highlights the ongoing, organic development of individuals and educational institutions involving relationships among people. It also points to the intangibles of multicultural education that are less recognizable than specific curriculum content, such as expectations of student achievement, learning environments, students' learning preferences, and cultural variables that influence the educational experience. *Critical pedagogy* draws upon experiences of students through their cultural, linguistic, familial, academic, artistic and other forms of knowledge. It also takes students beyond their own experiences and enables them to understand perspectives with which they disagree, as well as to think critically about multiple viewpoints, leading to praxis, or reflection combined with action (Freire, 2000).

Nieto's emphasis on critical pedagogy draws on the work of Freire (2000), linking multicultural education with wider issues of power, including socioeconomic and political equality, in what May (1999) calls "critical multiculturalism."

FIVE APPROACHES TO MULTICULTURAL EDUCATION

Christine Sleeter and Carl Grant connect the role of sociopolitical power to define multicultural education. Sleeter and Grant's article in *Harvard Educational Review* (Sleeter & Grant, 1987) provided an extensive review of the literature on multicultural education and explained five approaches. This work became a cornerstone of the field, upon which Sleeter and Grant (2006) continue to build. A brief overview and analysis of the five approaches articulated by Sleeter and Grant is provided here.

The goal of the first approach, which Sleeter and Grant call *Teaching the Exceptional and the Culturally Different*, is to equip students with the academic skills,

Multicultural education acknowledges and affirms the multiple identities that students bring to their learning. WILL & DENI MCINTYRE/PHOTO RESEARCHERS, INC.

concepts, and values to function in American society's institutions and culture. The positive attribute of this approach is that it spurred the movement toward modifying instruction and curriculum, commonly called differentiated instruction. Critics, however, claim that it has a tendency to emphasize an assimilationist perspective that positions students as holding deficits.

The second approach, *Human Relations*, consists of developing positive relationships among diverse groups and individuals to fight stereotyping and promote unity. Reducing prejudice and hostility are admirable goals, but according to its critics this approach tends to simplify culture and identity and avoids analyzing the causes of discrimination and inequality. Without a critical perspective, the Human Relations approach runs the risk of falling into the trap of feel-good tactics that are too soft on academic achievement.

Single-Group Studies is the third approach in the Sleeter and Grant analysis. The goal is to engage in an in-depth, comprehensive study that moves specific groups from the margins by providing information about the

group's history, including experiences with oppression and resistance to that oppression. The hope is to reduce stratification and create greater access to power. While there are many positive components to this approach, viewing it as a beginning or entry level approach to multicultural education may be the most appropriate appraisal of it. Criticism of this approach cites the unintentional effect of keeping groups such as people of color, women, people with disabilities, and working class people segregated and out of the mainstream curriculum. Other potential pitfalls are the possibility of promoting cultural separatism and the tendency for this approach to be implemented as a mere add-on.

The fourth approach to multicultural education is self-reflexively dubbed *multicultural education*. Sleeter and Grant use this seemingly redundant title to clarify this approach since so many other practices, such as those described in the first three approaches, are sometimes referred to as multicultural education. They cite Gollnick (1980) to explain that the multicultural education approach promotes a range of goals: the value of cultural diversity, human rights, respect for differences, alternative

life choices, social justice, equal opportunity, and equitable distribution of power. There are several criticisms of this approach that are discussed later in this entry. The most severe criticism argues that multicultural education promotes “particularism” and weakens social unification and academic rigor (Ravitch, 1990). Some scholars within the field of multicultural education point to the need for more attention to social structural inequalities and for teaching students the skills to challenge the disparities resulting from inequitable power structures.

The fifth approach, which is the approach Sleeter and Grant advocate, is *Education that is Multicultural and Social Reconstructionist*, which describes a complete redesign of an educational program. The notion of reconstructionism draws from Brameld’s framework to offer a critique of modern culture (Sleeter & Grant, 2006). Such a redesign recommends addressing issues and concerns that affect students of diverse groups, encouraging students to take an active stance by challenging the status quo, and calling on students to collectively speak out and effect change by joining with other groups in examining common or related concerns (Sleeter & Grant, 1987, 2006).

CURRICULUM DESEGREGATION AND EQUITY PEDAGOGY

The three major definitions of multicultural education by Banks, Nieto, and Sleeter and Grant helped to launch the field and continue to sustain a discourse that is constantly evolving. Geneva Gay (2004) has referenced the “shifting contours of multicultural education” and some of the reasons for the developmental changes in its intention, implementation, and effectiveness (p. 193). She demonstrates how multicultural education has changed over time by discussing it as a relatively young field, stemming from the time of *Brown v. Board of Education* (1954), that has grown through developmental phases. Gay emphasizes how multicultural education’s translation into practice is an ongoing dimension of its development. She cites two avenues for implementing educational equality within multicultural education: *curriculum desegregation* and *equity pedagogy*.

Curriculum desegregation requires analysis from every discipline and should not be relegated to the task of social studies and language arts. Gay points to several scholars who assert typologies that explain progression from simplistic curriculum reform to more comprehensive and complex forms. Other examples include lesson plans for specific subject areas. Gay (2003) also describes developmental paradigms that bridge multicultural theory and practice, pointing out that individual and institutional competencies vary widely, and that becoming a multi-

cultural educator is a process. In this she echoes one of Nieto’s seven characteristics (Bode & Nieto, 2008).

Instructional approaches and the shift to *equity pedagogy* are closely linked to the implementation of multicultural education through refining curriculum content (Gay, 2004). Gay explains that multicultural education places value on “*how* to effectively teach diverse students as well as *what* to teach them.” Achieving educational equity is a multi-dimensional goal that is addressed in the proposal for culturally responsive teaching, which consists of many domains:

The major domains include multicultural content; pluralistic classroom climates and learning environments; teacher attitudes and expectations toward diversity; building community among diverse learners; caring across cultures; use of multiple teaching techniques that are congruent with the cultural backgrounds, values, experiences, and orientations of different ethnic groups; developing personal efficacy and an ethos of success among diverse students; and using culturally informed assessment procedures to determine learning needs, knowledge acquisition, and skill proficiencies. (Gay, 2004, p. 214)

Citing a number of educational researchers who have demonstrated the effectiveness of multicultural education and its role in advancing academic achievement and participation in a democratic society, Gay confirms that educational desegregation and equality are advanced by multicultural education as the field continues to evolve:

Evidence increasingly indicates that multicultural education makes schooling more relevant and effective for Latino American, Native American, Asian American, and Native Hawaiian students as well. . . . Students perform more successfully on all levels when there is greater congruence between their cultural backgrounds and such school experiences as task interest, effort, academic achievement, and feelings of personal efficacy or social accountability. (Gay, 2003, p. 35)

INTERSECTIONS AND COMMONALITIES

These researchers’ explications of multicultural education deal with anti-racism, anti-oppression, and head-on indictments of policies and practices of schools and governments that maintain status quo privilege, power, and unequal schooling conditions. The aim of creating a more just society, by educating students for high academic achievement in which they become critically reflective and socially engaged is articulated by Banks (2004), Nieto & Bode (2008), Sleeter and Grant (2006) and Gay (2003, 2004). These aims remain consistent for multicultural educators as they reflect on challenges of the field.

SELF REFLEXIVE CRITIQUES FROM WITHIN THE FIELD

Despite the historical assertions of scholarship and efforts to inform the field of education, especially teacher education, the socially transformative qualities of multicultural education have not been universally understood or embraced. The uneven understandings of multicultural education theory have led to some critiques within the field. Sleeter and Bernal (2004) note that as more and more people have taken up and used multicultural education, it has come to be understood in a wide variety of meanings: "Ironically, (given its historical roots), a good deal of what occurs within the arena of multicultural education today does not address the power relations critically, particularly racism" (p. 240). This point is a prevalent concern among multicultural educators. McLaren and Torres (1999) argue, "in general, discourses in the US that deal with multiculturalism deal very little with the concept of racism and focus instead on the politics and affirmation of difference" (p. 44). Nieto, Bode, Raible, and Kang (2008) concur: "the political and transformative theories of multicultural education have often been neglected when translated into practice. As a result, even though multicultural education has made an important contribution to schools and communities, few long-term institutional changes have taken root" (p. 178). Gloria Ladson-Billings (2004) demands an examination of the intertwining of racialized identities with the political and economic history, and current social order of the United States. She notes a "new citizenship" being taken up by some people of color "who want to remake their world into a more just and equitable one" (p. 117). She sees the challenge for educators "to reveal and incite the power of democratic ideals for marginalized students in U.S. schools" (p. 122).

The challenge of translating multicultural theory into practice and maintaining a critical, transformative focus is increased by the contemporary globalized social order that is exponentially changing the way in which many scholars and educators understand culture and identity. For example, a great deal of research and practice in multicultural education has been influenced by questions of how culture might be defined or understood. Historically, in U.S. society and in many school contexts, the very notions of culture and difference have been delineated into static objects, as a metaphorical flag to wave. In that historical conception, culture is viewed as thing to have, rather than a practice of living, learning, performing, negotiating, and translating multiple experiences for oneself and one's community. This static framework for viewing culture implies that human identity, and by extension, human knowledge and student achievement, is contained by set boundaries and will remain unchanged.

Such a viewpoint is often referred to as a "modernist" conception of culture and cultural identity, which is

challenged by postmodern concepts in multicultural education (Dolby, 2000, Nieto, Bode, Kang & Raible, 2008). The understanding of culture as fluid and performative as opposed to a static fixture relates to other contemporary inquiries into human identity, such as questions about whether race is an inherent biological fact or a social construct. In 1998 the American Anthropological Association published a "Statement on Race" that indicted the attempts throughout U.S. history to establish division among biological populations as arbitrary and subjective by asserting "present-day inequalities between so-called racial groups are not consequences of their biological inheritance but products of historical and contemporary social, economic, educational and political circumstances" (p. 713).

Postmodern scholars criticize the argument that race is a biological rather than a social mechanism as an "essentialist" notion of race. Yet it is critical to note that abolishing notions of race does not end racism. Each scholarly definition of multicultural education reviewed here regards multicultural education as an anti-racist enterprise that assertively seeks to reduce prejudice. Yet these scholars point out that racism remains a stark reality and needs to be addressed by multicultural education even while contemporary discourse of identities call the notion of race into question (Nieto, Bode, Kang, & Raible, 2008).

Nieto, Bode, Kang, & Raible (2008) ask how multicultural education might transcend typically essentialist notions of race and other identities to reach a more nuanced, critical understanding of multicultural perspectives. As scholars of multicultural education reconceptualize the social constructs of race and racism, they acknowledge that multiple identities work in confluence in the anti-oppression goals of multicultural education. These identities, in addition to race, include social class, ethnicity, religion, language, age, ability/disability, sexual orientation, religion, gender, and other differences. However, because listing these identities as separate labels conflicts with postmodern frameworks on identity that insist identities and cultures are not static but shift and evolve in context, multicultural curriculum and instruction must evolve in a similar manner.

HETEROGENEITY AND HOMOGENEITY

Critical understandings of multicultural education address arguments about whether multicultural education should focus on differences or commonalities across and between ethnic groups. However, when multicultural education is understood within the multiple dimensions advanced by Banks (2006), Gay (2004), Nieto (2008) and Sleeter and Grant (2006) it cannot be viewed as an either/or enterprise.

Critics regard multicultural education, with its excessive emphasis on race and ethnicity, as divisive. They accuse its proponents of teaching to special interest groups to “disunite America” (Schlesinger, 1998). Many critics argue that teaching to a specific group emphasizes self-esteem at the expense of academic rigor. However, multicultural education insists on employing a range of strategies that aim for rigorous academic achievement for all students. Some of these educational strategies may involve inclusion of the knowledge, experiences, perspectives, and accomplishments of previously marginalized groups. This would be one of many approaches to multicultural education. Moreover, multicultural education asserts American ideals by upholding the unalienable constitutional right for every student to be prepared for full participation in a democratic society. However, a critical perspective demands that educators view the broad sociopolitical context of individuals and institutions, rather than labeling students or compartmentalizing them into rigid boxes. Such rigidity runs the risk of participating in and reinforcing stereotypes. At the same time, as Gay (2004) pointed out, the project of culturally responsive teaching requires addressing students’ cultural backgrounds through curriculum and pedagogy. Sleeter (2001) provided in-depth analysis of the critiques of multicultural education, addressing both the conservative and radical left critiques of multicultural education. Noteworthy among her multiple findings was that most of the conservative critics ignore the research by scholars in the field of multicultural education (Sleeter, 2001, p. 85).

In summary, the scholars in the field have asserted that multicultural education is a matrix of several dimensions, qualities, and approaches that encompass theories and practices as a process of educational reform. Multicultural education promotes equitable access and rigorous academic achievement for all students so that they can work toward social change.

MULTIPLE INTELLIGENCES

The theory of multiple intelligences, or MI theory, developed by Howard Gardner in the early 1980s, posits that individuals possess eight or more relatively autonomous intelligences that they use to solve problems and create products relevant to the societies in which they live. The eight intelligences identified by MI theory are linguistic, logical-mathematical, spatial, musical, bodily-kinesthetic, naturalistic, interpersonal, and intrapersonal. In conceiving of intelligence as multiple rather than unitary, the theory of multiple intelligences offers a very different perspective on human capabilities and potential than traditional conceptions of intelligence as measured by IQ tests.

GENERAL INTELLIGENCE VERSUS MI THEORY

The traditional conception of intelligence often referred to as IQ first came about in France in the early 1900s when psychologist Alfred Binet developed a 30-item intelligence test for identifying French school children in need of special education. Binet's work was popularized in the United States by Stanford psychologist Lewis Terman who published a revision of Binet's test in 1916 that came to be known as the Stanford-Binet scale.

Around the same time that Binet was developing his scale, English psychologist Charles Spearman (1904)

published a paper on general intelligence in which he asserted that all forms of intellectual activity stem from a unitary or general ability for problem-solving. While Binet had developed his scale with the goal of predicting children's school performance and not as a measure of intelligence across all endeavors, the results of his and Terman's work were taken as support of Spearman's theory. Spearman's conception of general intelligence became the prevailing view of intelligence over the course of the 20th century, though it did have its critics. Both Thorndike (1927) and Thurstone (1938) were prominent researchers who argued that an individual's intellectual abilities could not be measured by a single construct. Nonetheless, the conception of intelligence as a unitary ability gained hegemony among both psychologists and lay-people.

A challenge to this view of intelligence came in 1983 when Gardner laid out his theory of multiple intelligences in a work titled *Frames of Mind*. Gardner's theory emerged from his consideration of several simple but powerful questions:

Are the brilliant chess player, violinist and athlete "intelligent" in their respective disciplines? If they are, then why do our tests of "intelligence" fail to identify them? In general, why does the traditional construct of intelligence fail to take into account such large areas of human endeavor? (Gardner, 2006, p. 6)

In these words, Gardner voices his concerns with the intelligence test designed by Binet and its underlying acceptance of intelligence as a single, unitary construct. In *Frames of Mind*, Gardner (1983) lays out his own conception of intelligence which differs from Binet's in several fundamental ways. First, proponents of Binet's conception of intelligence typically define intelligence as the trait or quality measured by an intelligence test. As psychologist E.G. Boring (1923) famously declared, "Intelligence is what the tests test" (p. 35). Gardner (2006), in contrast, defines intelligence as "an information-processing potential to solve problems or create products that are valued in at least one culture" (p. 235). Second, the traditional conception of intelligence conceives of a high IQ score as indicative of an individual's ability to be high achieving across a wide range of endeavors. In contrast, MI theory argues that individuals who demonstrate a particular aptitude in one intelligence will not necessarily demonstrate a similar aptitude in another intelligence. For example, an individual who demonstrates an impressive level of musical intelligence may be far less skilled when it comes to bodily-kinesthetic or spatial intelligence, or vice-versa. Finally, while most proponents of general intelligence regard intelligence as an innate trait which one can do little to change, multiple intelligences theory conceives of intelligence as a

combination of heritable potentials and of skills that can be acquired and enhanced by appropriate experiences. In other words, while one individual may be born with a strong potential for musical intelligence, another individual can strengthen his or her musical intelligence through study and practice.

A common misunderstanding regarding MI theory is that people possess some intelligences and not others. According to MI theory, with the exception of individuals suffering from severe brain damage, all individuals possess the full range of intelligences. Thus, an individual's profile of intelligence may include a relatively low aptitude for musical intelligence, but that individual is misunderstanding MI theory if he or she claims to have no musical intelligence. Another misunderstanding is that every individual is superior in at least one of the intelligences. Individuals do differ in their levels of strength and weakness for each of the intelligences; however, there is no guarantee that every individual will demonstrate superior aptitude in at least one intelligence (Gardner, 1983).

IDENTIFYING AN INTELLIGENCE

Multiple intelligences theory has proved controversial in the psychology world. Perhaps the main source of this controversy is the evidence upon which the theory is based. Many other theories of intelligence are based entirely upon empirical data collected from psychometric instruments or experimental studies. These studies typically involve presenting subjects with a number of test items that are believed to measure intellectual capabilities. MI theory came about differently. Rather than conducting a series of experiments, Gardner (1983) developed his theory of multiple intelligences by synthesizing research from fields as diverse as evolutionary biology, neuroscience, anthropology, psychometrics as well as psychological studies of prodigies and savants. By drawing upon findings from these many diverse sources, Gardner developed the following set of criteria for identifying an intelligence:

- It should be seen in relative isolation in prodigies, autistic savants, stroke victims or other exceptional populations.
- It should have a distinct developmental trajectory.
- It should have some basis in evolutionary biology.
- It should be susceptible to capture in symbol systems.
- It should be supported by evidence from psychometric tests of intelligence.

It should be distinguishable from other intelligences through experimental psychological tasks.

It should demonstrate a core, information-processing system. (Gardner, 1998).

Through application of these criteria, Gardner identified eight distinct intelligences. Linguistic intelligence allows individuals to create and understand products involving language such as poems, political speeches, and newspaper articles. Logical-mathematical intelligence allows individuals to develop equations and proofs, make calculations, and solve abstract problems. Scientists, analytic philosophers, and computer programmers typically possess profiles of intelligence high in logical-mathematical intelligence. Spatial intelligence enables individuals to use maps and other forms of graphic information in order to navigate around or through complex terrains. Musical intelligence allows individuals to create and interpret different types of sound patterns and combinations. Bodily-kinesthetic intelligence involves using one's own body to create products or solve problems. Dancers, artists, and surgeons all require a profile of intelligence high in bodily-kinesthetic intelligence. Interpersonal intelligence captures an individual's ability to observe and understand other people's moods, desires, skills, motivations, and intentions while intrapersonal intelligence reflects an individual's ability to recognize and assess these characteristics within himself.

Gardner's original theory of multiple intelligences identified the seven intelligences described here. However, in the mid-1990s, Gardner found that naturalistic intelligence met the above criteria for identification as an intelligence as well. According to Gardner, naturalistic intelligence enables individuals to recognize and distinguish among products of the natural world such as animals, plants, rock configurations, and weather formations. Individuals with high levels of naturalistic intelligence might be drawn to careers in botany, meteorology, and veterinary science.

Yet another misconception about MI theory is that intelligences are constantly being identified and added. This misconception comes about in part because of the literally hundreds of psychologists, educators, and writers who have begun writing about various intelligences since Gardner's original publication of *Frames of Mind* in 1983. In truth, however, naturalistic intelligence is the only intelligence that Gardner has identified and added to the original set of intelligences originally described in *Frames of Mind*. Between the early 1980s and the early 2000s, researchers have suggested a number of additional intelligences, including moral intelligence, humor intelligence, cooking intelligence, and even sexual intelligence. However, as of 2007, none of these suggested intelligences has met the criteria cited above for identification as a unique intelligence.

One partial exception is the proposal of existential intelligence (Gardner, 1999). Existential intelligence has been described as the intelligence of big questions—a capacity to consider issues of life, death, love, war, and being. One might expect philosophers, poets, and theologians to demonstrate a particular aptitude for existential intelligence. Gardner (2006) has referred to existential intelligence as a half-intelligence because research to date has found existential intelligence to meet several of the criteria for identification as a unique intelligence but not all of them. Thus, it is not yet clear whether existential intelligence warrants identification as its own unique intelligence or whether the capacity to reflect upon big questions is better conceived of as a component of one or more of the existing eight intelligences. As of 2007, Gardner has held off on classifying existential intelligence as a full-fledged ninth intelligence.

Of course, it is entirely possible that early decades of the 21st century, research in fields such as genetics or neuroscience will demonstrate that existential intelligence or other intelligences do meet the criteria for inclusion as an intelligence. It is also possible—perhaps even likely—that research in these fields will reveal that hitherto identified intelligences such as logical-mathematical intelligence consist of several sub- or component intelligences. As brain imaging techniques improve and researchers' understanding of the human genome increases, there is little doubt that MI theory will adapt and change. That said, the precise number and boundary of the intelligences is less important than the overarching principle of MI theory: namely, that intelligence is better understood as multiple and specific rather than unitary and general (Chen & Gardner, 2005; Gardner, 2006b).

APPLICATIONS OF MI THEORY

Multiple intelligences theory has had a substantial impact upon the world of education; however, Gardner did not develop MI theory with an intended educational agenda or audience. Rather, Gardner developed his theory of multiple intelligences with the goal of drawing upon dramatic advances in the fields of neuroscience, biology, and psychology to offer an alternative way of thinking about human cognition. Nonetheless, numerous educators embraced the idea of multiple intelligences almost from its inception. Hundreds of schools, teachers, and researchers at all different levels and in many different countries and settings have applied MI theory to the practice of education various ways. Examples include schools that use MI theory to provide teachers with a common vocabulary for discussing the learning of individual students. Other schools teach students about the concept of intrapersonal intelligence in order to encourage them to reflect upon their own strengths and weaknesses. Still other

schools seek to deepen student engagement by designing curricula that draw upon different intelligences in students' investigation of a particular topic.

One of the first schools to draw extensively upon the principles of MI theory was the Key Learning Community in Indianapolis, Indiana. The Key Learning Community was founded by a team of teachers in 1987 with the mission of giving “equal emphasis for every student to each of the eight areas of intelligence: linguistic, musical, logical-mathematical, naturalistic, spatial, bodily-kinesthetic, interpersonal and intrapersonal” (Key Learning Community, 2007). The Key Learning Community regards MI theory as the cornerstone of its educational program, and, according to the Key Learning Community principal, the school's schedule “allows students to study all eight intelligences during the regular school day” (Key Learning Community, 2007). Interest in the work of the Key Learning Community has been widespread. The school hosts a formal visitors' program and annual summer institute which draw educators from across the United States and world interested in seeing the “world's first multiple intelligence school” in action.

If the Key Learning Community represents one of the earliest applications of MI theory, then Danfoss Universe represents one of the most ambitious. Danfoss Universe is a 10-acre science experience park that opened in Sonderberg, Denmark, in 2005. The park is divided into three parts: the outdoor park, a museum, and the Explorama. The Explorama is a museum-sized building with more than 50 different activities designed to teach visitors about their various intelligences (Danfoss Universe, 2007). For example, an intrapersonal exhibit called Mindball challenges contestants to lower their own stress levels deliberately; if they can do so, an electrode headband converts this reduction in stress into a force that can propel a ping pong ball into the orbit of the opponent. An exhibit on musical intelligence enables participants to create their own melodies on a theremin, one of the earliest electronic musical instruments. Finally, an exhibit on linguistic intelligence gives participants the opportunity to practice a few Japanese words and then examine a visual representation of their vocalization superimposed over that of a native Japanese speaker. Through trial and error, participants can improve their tone and pronunciation. With these and many other exhibits, Danfoss Universe encourages visitors to the Explorama to reflect upon their own profiles of intelligence. Moreover, in a subsequent addition, visitors have a chance to predict their performances on the various activities. At the end of their visit, they can compare their predictions with the actual outcome—another, quite veridical measure of intrapersonal intelligence.

RESEARCH ON MI THEORY

Since the late 1970s, numerous researchers have investigated the influence of MI theory. Here, two such studies are particularly notable, though in very different ways. Project Spectrum was a 10-year study conducted from 1984 to 1993 that sought to identify intellectual strengths in young children and then investigate the impact of an MI-based intervention program on first grade students at risk for school failure. As part of this study, both teachers and researchers observed at-risk first graders over the course of the school year as they participated in learning center activities designed to assess the absolute and relative strengths of the eight intelligences. From this study, Chen and Gardner (2005) report that “At-risk students, although they often perform poorly in traditional academic areas, are not necessarily low performers in all areas of learning” (p. 90). Chen and Gardner (2005) further report that identifying and nurturing these at-risk children’s strengths led to statistically significant increases in these children’s self-direction, self-confidence, positive classroom behavior, positive affect, self-monitoring, and active engagement. In short, then, it seems that using MI theory to identify children’s profiles of intelligence and relative strengths can play a role in deepening these children’s engagement and academic achievement.

A second study, the Project on Schools Using Multiple Intelligences Theory (SUMIT), was a three-year national study conducted from 1997 to 2000 that involved site visits, data analysis, and interviews with teachers at 41 schools that employed MI theory in some capacity. From this study, Kornhaber, Fierros and Veneema (2004) report that, after drawing upon MI theory, 78% of the schools in their study reported improved standardized test scores; 78% reported improved academic performance by students with learning difficulties; and 81% reported improvements in student discipline. More than half of these schools attributed these improvements to the implementation of curriculum and practices inspired by MI theory. Both Project Spectrum and Project SUMIT, then, seem to offer clear evidence of the promise that multiple intelligences theory holds for educators, schools, student performance, and school culture.

Part of the landscape in psychology and education since the early 1980s, MI theory has demonstrated considerable staying power. Its fate within psychology is likely to depend less on further tinkering with psychometric instruments and more on the convergence of evidence from neuroscience and genetics. These ongoing lines of research will indicate whether intellect is in fact

pluralistic and, if so, whether the delineation suggested by Gardner comports with emerging data. Within education, MI theory promises to continue to appeal to teachers whose daily experience supports a view of young persons as having quite individual profiles of intellectual strengths and weaknesses. Whether the policies supported by governments will honor these individual differences or seek to ignore or reduce them through the administration of standard curricula and assessments remains to be seen.

NEO-PIAGETIAN THEORIES OF DEVELOPMENT

In his 1992 review of Jean Piaget's theory, Harry Beilin compared its influence on the study of cognitive development to that of Shakespeare on English literature. Any theorist who has studied cognitive development in children from the middle of the twentieth century onward has been a neo-Piagetian in that broad sense. However, the subject of this entry is a smaller group of researchers who have called themselves neo-Piagetians. Because the *neo-* label directs attention back to a theory's origins, most neo-Piagetian researchers eventually chose other names that focused on their theories' new elements. Thus Kurt Fischer's neo-Piagetian theory became known as skill theory (Fischer & Pipp, 1984; Schwartz & Fischer, 2004) and Robbie Case's evolved into central conceptual structure theory (Griffin, 2004).

HOW NEO PIAGETIAN THEORIES DIFFER FROM PIAGET'S THEORY

Neo-Piagetian theorists kept Piaget's idea that the progress of cognitive development is more like climbing a series of stairs (the stages) than walking smoothly up a ramp. They also agreed with Piaget that biological maturation sets broad upper limits on the kinds of thinking children are capable of doing at particular ages. All of the neo-Piagetians also shared Piaget's conviction that children's thinking reflects their developing internal mental structures (Case & Okamoto, 1996). However, each of the neo-Piagetians combined this general premise with ideas about the influence of experience on development

that were more analytically specific and more attuned to cultural and individual differences than anything found in Piaget's theory. For example, they considered how biological maturation of the central nervous system during the first years of life increases the speed with which children process information—an idea introduced in 1970 by Pascual-Leone. The neo-Piagetians linked that maturing processing speed to increases in working memory capacity that, in turn, set upper limits on the complexity of problems a child is likely to be able to solve.

The neo-Piagetians also have drawn on information-processing and linguistic theorists' ideas about the content-domain specificity of cognition. Piaget's theory evolved to include provisions for unevenness in the sophistication of a child's reasoning across different kinds of problems, but this domain specificity is more fundamental to neo-Piagetian theories. The influence of the information-processing paradigm also is evident in the neo-Piagetians' tendency to analyze Piaget's and other cognitive tasks in ways that highlight why one problem may be more or less difficult than another, even within the same content domain. Australian neo-Piagetian Graeme Halford (Andrews & Halford, 2002) became especially well known for his focus on this kind of task analysis.

The neo-Piagetians also adopted principles from social-cognitive theories such as that of Lev Vygotsky. These principles allowed them to give more extensive consideration than can be found in Piaget's work regarding how culturally determined experiences and minute-by-minute interactions with teachers and peers influence a child's intellectual performance. Although biology sets upper limits on performance, a child's culture and everyday

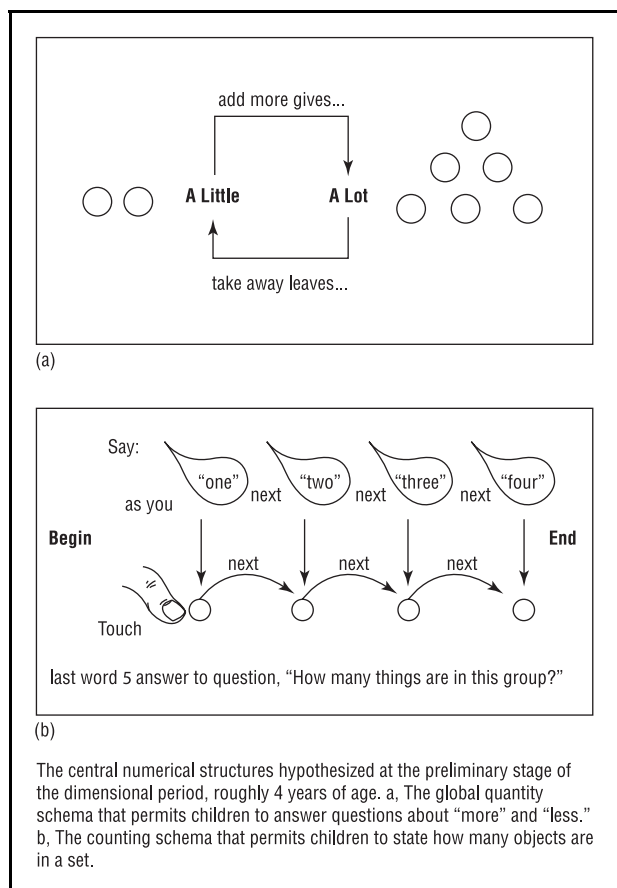

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

experience might not provide the information and practice needed for development up to that limit. Neo-Piagetian theories include mechanisms to account for cultural and socio-economic differences in patterns or rates of cognitive development. These theories also are compatible with the idea that individual children differ in their ability to absorb the experiences available in their culture.

With their joint consideration of biology, the precise requirements for doing a task, and the contributions of experience, the neo-Piagetian theorists have elaborated on possible mechanisms of developmental change, the *how* of development that was only sketched in very general terms by Piaget (Case, 1984; Case, 1996; Griffin, 2004; Schwartz & Fischer, 1994).

The neo-Piagetians' interests in mechanisms of development and in optimizing learning offer educators more explicit guidance than is available in Piaget's theory. A number of neo-Piagetians have proposed theories with relevance for classroom practices. However, Canadian psychologist Robbie Case (1945-2000) prob-

ably is the neo-Piagetian whose work has had the most influence on education.

OVERVIEW OF CASE'S THEORY

Case might be considered the quintessential neo-Piagetian researcher because he dedicated his own theorizing and research efforts to working explicitly within the historical framework of Piaget's ideas. However, Case tried to remedy some of the deficiencies in Piaget's theory by incorporating ideas and methods from other traditions, especially Vygotsky's social-constructivist theory, information-processing theories, linguistics, and new findings in developmental neuroscience (Case, 1996).

Like Piaget's own grand theory, Case's neo-Piagetian theory is hard to summarize because it developed changing substantially across the span of Case's own research career and with work that his colleagues continued after his death. In his early work, Case focused on the broad implications of central processing speed and working memory span (e.g., Case, Kurland, & Goldberg, 1982). These ideas were retained in later versions of the theory, but there was more attention to the nature and development of children's mental representations in each of several cognitive domains—the central conceptual structures. In a 1996 monograph, Case and his colleagues investigated central conceptual structures underlying reasoning about number, space, and narrative (Case, 1996). All of these structures were described as going through stages that were labeled pre-dimensional, unidimensional, bidimensional, and integrated bidimensional and that characterized children's thought at about ages 4, 6, 8, and 10 years. Figures 1 and 2 show the central conceptual structures for number hypothesized to be characteristic of middle-class children in a technological society at about age 4 years (Figure 1) and at about age 6 years (Figure 2). Figure 1 shows that typical 4-year-olds, who are in the pre-dimensional stage, have not yet coordinated two ideas about number—the idea of comparisons between smaller and larger quantities and the idea of counting off a set of objects, saying number names in sequence. In contrast, typical 6-year-olds (Figure 2) have a unidimensional central numerical structure that coordinates several ideas along a number line that they can use to do a variety of arithmetic reasoning tasks.

Case and his colleagues (Case, 1996) also described how a sequence of increasingly complete and coherent central conceptual structures might organize children's developing reasoning in other content domains besides number. Although these domain-limited structures were expected to develop more or less in synchrony because they were all affected by common biological limits, the content of each structure also was expected to be influenced by

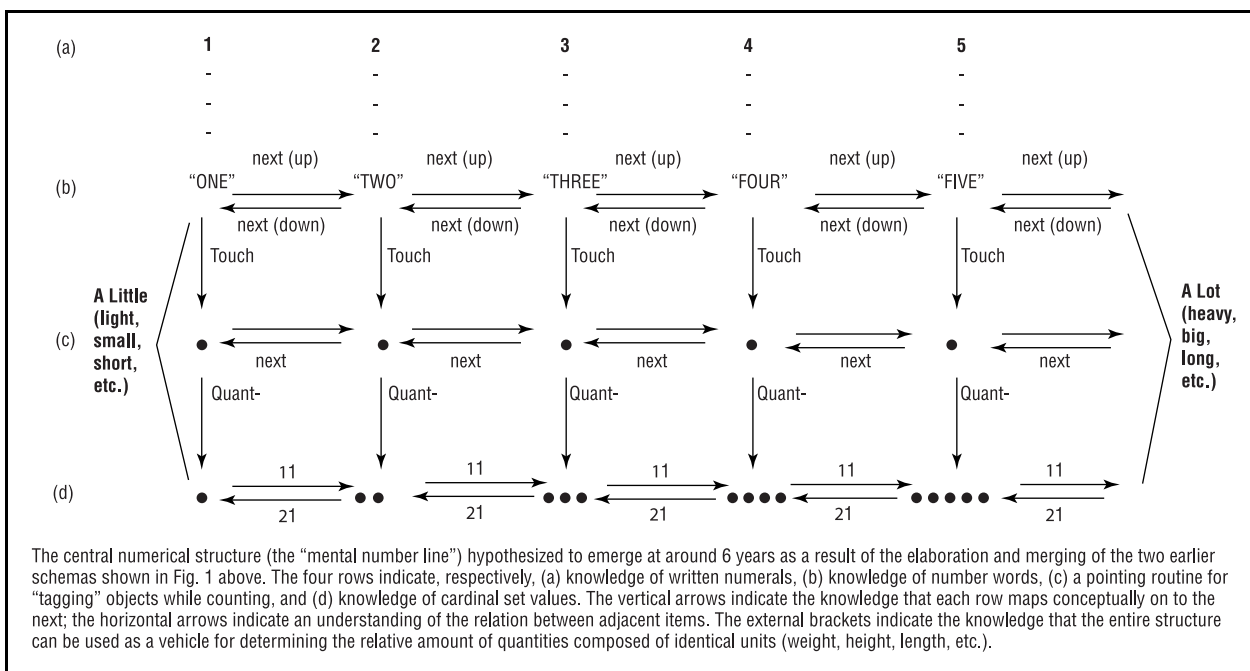

Figure 2 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

cultural and individual experience, which gave them some independence from one another.

The idea that biological maturation limits the speed with which a child of a given age is likely to be able to process information, or think, is central to Case's interpretation of development. With increasing age, the child's neurons become more extensively coated with a fatty myelin sheath, which speeds transmission of information along the nerve fiber. Another key change with age is that the pattern of connections among the nerve cells in the brain becomes better specialized—unnecessary connections drop out and important ones are strengthened with a combination of time and experience. Because older children can think faster than younger children, they can keep more concepts in mind at the same time. Case and his colleagues first demonstrated the link between thinking speed and memory span in a study of counting speed and memory for digits (Case et al., 1982). The principle extends far beyond arithmetic. In any content domain, familiarity and practice can help children process information more quickly and solve more complex problems. However, chronological age and biological maturation set limits on how much can be achieved with practice.

In Case's theory, one of children's developing mental structures is devoted to the representation of space. These spatial structures are reflected in children's drawings,

which become increasingly organized along multiple spatial axes as children grow older. A 4-year-old's figure is likely to be floating in space, but a 6-year-old's drawing of a person usually stands on a ground line and may be accompanied by other objects, such as an animal or tree, arrayed along the same horizontal axis. Dealing with the vertical and depth dimensions comes later, and it is not until age 10 years or more that children coordinate all of these dimensions well. Even precociously talented young artists are not likely to represent spatial axes in a way much beyond that typical of their chronological age, although their drawings of each figure may be beautifully detailed and realistic (Case & Okamoto, 1996). Thinking in a coordinated way about multiple dimensions of space also is important in playing games such as checkers, in reading or drawing maps, and in making scientific judgments about relations within a series of objects (Case, 1996).

The ways in which culture might influence the separate development of various central conceptual structures was illustrated dramatically in a study comparing children who had experienced Western technological culture and schooling with those who had not. Case's colleague Fiati found that children who were living in isolated rural villages in the Volta region of central Africa and who had not experienced any Western-style schooling, performed at the same levels as urban children their age on tasks involving the coordination of ideas in a story, a task hypothesized to

ROBBIE CASE

Canadian psychologist Thomas Robert “Robbie” Case was born in Barrie, Ontario, in 1944. After earning a B.Sc. in psychology from McGill University in 1965, he taught high school English and physics in a kibbutz in Israel for a year. Case received his M.A. (1968) and Ph.D. (1971) in education from the University of Toronto’s Ontario Institute for Studies in Education (OISE). He was a professor at the University of California Berkeley and at Stanford before becoming director of the University of Toronto Institute of Child Study, where he remained until his death in 2000.

Case’s research centered on child cognitive development, exploring the development of young children’s thinking patterns, aiming to improve how special needs and impoverished students learned. He included Piagetian theories with his findings to create most advantageous instruction for these students, especially in math. Just before his death, Case began to apply his findings about children to civilizations, working with social scientist Tom Rohlen.

Case contributed chapters to numerous books and wrote many theses, grants, and journal articles, as well as *Intellectual Development: Birth to Adulthood* (1985) and *The Mind’s Staircase* (1992). He also served as a consulting reviewer for several editorial boards.

Heidi H. Denler

depend on Case’s central conceptual structure for narrative. This showed that there was nothing generally wrong with the children’s ability to do complex thinking. However, life in the village had offered very little experience with numerical tasks, and the children’s performance on tasks involving Case’s central conceptual structure for numbers (see Figure 1) was immature. In less extreme cross-cultural comparisons, Case and his colleagues found that central conceptual structures developed at about the same rate for children in the United States, Canada, China, and Japan. However, socio-economic differences within a culture could be associated with large differences in developmental rate (Case, 1996; Case, Griffin, & Kelly, 2001).

EDUCATIONAL APPLICATIONS OF CASE’S THEORY

Although some of Case’s early theorizing concerned development in infancy and the toddler years (Case,

1985), much of his work was concerned with how children’s thinking changes between about age 4 and age 10 or so (Case, 1996). This makes his work especially relevant for educators working with children in preschool and elementary school.

A major implication of Case’s work, consistent with the implications of information-processing theories, is that young children should not be expected to think about too many new ideas at once. For example, typical 6-year-olds are much more likely to give the correct answer to the problem “ $6 + 2 = ?$ ” than they are to the related problem “ $6 + ? = 8$ ”, which is expressed with a missing addend. To solve a missing addend problem, a child needs to understand several unfamiliar symbols. Case (1978) found that children were more successful with missing addend problems if they were gradually introduced to the non-numerical elements of an equation before doing the arithmetic. Throughout his career, Case was concerned with analyzing exactly what a child needed to know and manipulate in order to solve common school problems and with how age and cultural experience may have left some children unable to meet classroom expectations (Case, Griffin, & Kelly, 2001).

When everyday experience has not helped children develop a particular kind of central conceptual structure, carefully planned instruction has been shown to help children catch up. One of Case’s colleagues, Sharon Griffin, developed a compensatory education program for first graders from low-income families that she called Rightstart (Griffin, 2004; Griffin, Case, & Siegler, 1994). The goal of this program was to give these children lessons that would fill in gaps in their central conceptual structure for numbers (Figure 2). Children in the program and those in a control group were pre- and posttested using exams containing items influenced by Case’s theory, and those who had been in the Rightstart program did better on the posttest.

Case’s theory also has contributed to the design of more effective instruction on problems that are likely to be difficult for all children, regardless of their family background, such as understanding rational numbers. Rational numbers are percentages, decimals, and fractions. These topics usually are introduced in the late elementary years and often are not mastered fully even by adults. Moss and Case (1999) found that fourth graders achieved a deeper understanding of rational numbers in a curriculum that focused on step-by-step teaching of a conceptual structure for these numbers. The curriculum started with percentages, using exercises that involved observing and manipulating liquids in beakers and other objects that were partly full. Discussion at this point was all in terms of percentages. Then children were introduced to decimal notation using large number lines on the floor, and links

between decimal fractions and percentages were emphasized. Finally, traditional fractional notation was taught and linked with the other two forms of rational number notation. Children who experienced this curriculum had a deeper understanding of rational numbers than children in a control group.

NORM-REFERENCED SCORING

Norm-referenced scoring is the process of comparing one person's score relative to a group in order to determine the relative standing of that person to the group in the area being tested (Thorndike, 2005). It is comparing one's score relative to the performance of others. Norm-referenced scoring is then a system of rank ordering and a way to give meaning to raw scores. Raw norm-referenced scoring does not indicate mastery and/or competency of skills. The group being compared against in norm-referenced scoring is termed the normative group or normative sample. The normative group should be representative of the person that is being compared against it (i.e., gender, race, geographical region, age, acculturation, language) in order for the scores to be meaningful.

Several key factors should be considered before using a norm-referenced assessment. One important factor is that the norming is recent, meaning that the sample that was used to collect the data is relatively recent. A good rule is to make sure that the norming data is no more than 10 years old. Also the normative groups should have been fairly large. Other important factors to consider are the reliability and validity of the scores that are given. Reliability refers to precision of scores. A highly reliable score is one which the tested person would achieve again if the same test were given a second time. Validity refers to the idea that the score is truly measuring what it purports to measure. Reliability and validity are reported in a range from zero to one. The closer to one the reported number is, the more reliable and valid the measure.

Norm-referenced scores are derived scores that can be reported in multiple forms. Raw scores (the actual number of items answered correctly) are not reported in norm-referenced scoring but are instead used to derive all other types of scores that can be reported. Norm-referenced scores can be reported in either a developmental format

Norm-referenced Scoring

or a relative standing format. Both formats have strengths and weaknesses associated with them.

DEVELOPMENTAL SCORES

Developmental scores are ordinal scores, ordered from best to worst or worst to least in which adjacent values indicate a higher or lower value (Thorndike, 2005). There are two forms of developmental scores: age-equivalent or grade equivalent. The norms in these forms are then the average raw score of a particular age or grade indicated in the norm sample. For example, when using age-equivalents, an age equivalent of 12 would have been calculated in the norm sample by averaging all raw scores obtained by 12-year-olds. This calculation works in the same manner for grade equivalents. To say that a child is scoring at the third grade level indicates that a child obtained a raw score that was equivalent to the average raw score of third graders in the normative group. This statement does not, however, indicate in which way the score was obtained. The questions answered correctly by the person may be different from which questions were answered correctly in the norm sample. There is not an equal interval between scores. Age and grade equivalent scores have the advantage of seeming to be easily interpretable. A person's level of performance is compared to familiar milestones of age or education, which makes them easily explainable to a person with limited knowledge of score interpretation. For example, it is easy for a teacher to tell parents that their child is reading at a third grade level.

There are several drawbacks, though. Typically in the norm sample, representation of every month in school or every age is not possible. For example, the norm sample may have included students in grade 2.0, 3.0, and 4.0. The average raw score is easily obtained for those grades. But raw scores that fall in between these levels have to be translated into grade equivalents. Therefore, if a raw score of 30 indicated a grade equivalent of 2.0, and a raw score of 38 indicated a grade equivalent of 3.0, the raw scores of 31 to 37 have to be interpolated (assigned arithmetically to grades between or inside those tested (Thorndike, 2005). Not all grade or age equivalents may be assigned a raw score and there may not be equal intervals between scores or equal growth between years. For example, a raw score of 35 may translate into an age-equivalent of 7 years, a raw score of 36 may translate into an age-equivalent of 7 years, 1 month, and a raw score of 38 may translate in to an age-equivalent of 7 years, 8 months. Also, there may be possible raw scores that fall outside average raw scores obtained in the norm sample, which would then require extrapolation (arithmetically calculating outside the range tested) for those raw scores. For example, Test A has raw scores

possible from 0 to 40. Grades 3.0 to 6.0 were included in the norm sample, and a raw score of 34 was the average for a sixth grader. The raw score of 40 falls outside the norm sample and would be calculated to be a grade equivalent greater than 6.0. Another important consideration with grade and age equivalents is whether there is meaning in assigning this type of score. For example, in most cases these types of score lose meaning in high school subject matter assessments. If a student is able to take biology in any grade of high school, it would not make sense then to administer a biology test and then to tell a student that he or she performed at, for example, a ninth grade equivalent.

SCORES OF RELATIVE STANDING

Scores of relative standing can also be broken into several formats: standard scores, scaled scores, and percentiles. These types of scores are useful for interpreting scores when grade or age is not a concern. Standard scores represent deviations (or the scatter of individual scores in the norm group) from the mean (Thorndike, 2005). Standard scores are considered to be at equal intervals; the difference between two points is the same throughout the scale. Standard scales are useful when the norm group is distributed among all scores possible. The standard score may be reported as a z-score, where the mean (or average) raw score is transformed to equal zero. Fifty percent of all scores will then fall above zero and 50% will fall below zero. This type of score is often complicated because raw scores may indicate a negative standard score. To help with this problem, standard scores are typically converted into other scaling systems which are easily comparable and retain the same properties. For example, the average IQ standard score of 100 is equivalent to a z-score of zero. A scaled score is a standard score that has been converted to a mean of 10 with a standard deviation of three.

Percentile equivalents are also directly comparable to standard scores. A percentile is the percentage of people in the norm group that the test taker performed as well as or better than (Thorndike, 2005). For example, a percentile score of 67 would indicate that a person performed as well or better than 67 percent of the norm sample. Percentile scores have one crucial difference from the scaled scores. Percentiles are not in an equal interval format. There is smaller variation in the percentiles nearer the mean and larger variation in the percentiles further from the mean. For example, there is little difference in raw scores that equate to percentile ranking of 50 or 55, whereas there is typically a great difference between the raw scores that compute to percentile rankings of 90 and 95.

Overall normative scoring is useful for making comparisons of performance against a similar group but not useful for determining mastery of content.

NORM-REFERENCED TESTING

Norm-referenced testing is integral to the practice of psychological and educational testing. Originated in the work of modern statistics, this assessment method assumes that human traits and characteristics, such as intelligence, academic achievement, and behavior, are distributed along a normal probability or bell-shaped curve (hereafter, referred to as the normal curve). The normal curve represents the norm or average performance of a population and the scores that are above and below the average within that population. The norms for a test include percentile ranks, standard scores, and other statistics for the norm group on which the test was standardized. A certain percentage of the norm group falls within various ranges along the normal curve. Depending

on the range within which test scores fall, scores correspond to various descriptors ranging from deficient to superior.

A Norm-Referenced Test (NRT) compares an examinee’s test performance to those of the examinee’s same-age peers from the test’s norm group. This comparison permits a more meaningful interpretation of the individual’s score. An examinee’s test score is compared to that of a norm group by converting the examinee’s raw scores into derived or scale scores. As shown in Figure 1, derived scores correspond to the normal curve, thus providing an interpretive framework for examinees administered the NRT. The norm group can consist of a larger population, such as a representative population of children from the United States (i.e., a national norm group), or it can consist of a smaller, more limited population, such as all children in an individual school or school district (i.e., a local norm group).

DERIVED SCORES

The conversion of examinees’ raw scores into derived scores provides a system of common metrics that facilitate test interpretation. There are multiple derived scores reported for NRTs; however, the more common ones used for interpretive purposes are standard scores, standard deviations, scale scores, T-scores, percentile ranks, age-equivalent scores, and grade-equivalent scores. A standard score has a statistical mean or average of 100

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

and conveys how far an examinee's test score varies or deviates from the average of the distribution. The extent to which a score varies or deviates from the average is expressed as a standard deviation. For example, a standard score of 115 on a NRT, such as an intelligence quotient (IQ) test, is one standard deviation above the mean of 100 and falls within the High Average range.

Scale scores yield information about an examinee's performance on a sub-domain or subtest of a NRT. These scores have a mean or average of 10 and a standard deviation of 3 points. Therefore, a scale score of 7 on a NRT subtest indicates that the examinee's skill, as measured by the subtest, is one standard deviation below the mean of 10 and corresponds to the Low Average range. T-scores are a different distribution of standard scores in that the mean of the distribution is 50 with a standard deviation of 10 points. NRTs assessing behavior typically report T-scores. Consequently, a T-score of 60 on a behavior rating scale is one standard deviation above the mean of 50 and corresponds to the High Average/At-Risk range. Percentile ranks indicate an examinee's position relative to the norm group. A percentile rank is a point in the distribution at or below which a certain percentage of scores falls. A child obtaining a percentile rank of 85 on an intelligence test indicates that the child's performance is equal to or greater than 85 percent of the child's same-age peers in the test's norm group. It does not mean the child obtained 85 percent of items correct on the NRT.

Grade- and age-equivalent scores are two of the most commonly used scores to report test results, yet they are also commonly misunderstood. These scores indicate that a student has attained the same raw scores (or number of items correct) as the average student of a certain grade or age level in the test's norm group. For example, if a student obtains a grade-equivalent score of 4.5 on a test of basic reading skills, this means the student obtained the same raw score as the average student in the fifth month of the fourth grade in the test's norm group. It does not mean the student acquired or demonstrated the same level of proficiency consistent with curricular expectations as the average student in the fifth month of the fourth grade at the student's school. Likewise, if a student obtains an age-equivalent score of 8.0 years on a test of basic reading skills, this means the student obtained the same raw score as the average 8-year-old student in the test's norm group. It does not mean the student acquired or demonstrated the same level of proficiency consistent with curricular expectations as the average 8-year-old student in the student's school. Consequently, grade and age-equivalent scores should not be interpreted literally. It is critical that test administrators and consumers understand the meaning and interpretation of these and other derived scores, as

misinterpretation can lead to serious consequences for the examinee, including possible misdiagnosis, misclassification, and/or inappropriate educational placement and services. Sattler and Lyman provide further, extensive information about these and other derived scores used for testing interpretive purposes.

Of note is the fact that NRTs are imperfect by nature. The scores yielded by NRTs are referred to as observed scores versus absolute or true scores. An observed score is one attained by an examinee, whereas a true score is one that is error-free and hypothetical in nature. For this reason, norm-referenced standard test scores have bands of error, which are expressed as either 90 percent or 95 percent confidence intervals. The 90 percent confidence interval indicates the range of standard scores within which an examinee's true score would fall 90 out of 100 times on repeated assessments. Likewise, the 95 percent confidence interval, a more conservative estimate, indicates the standard score range within which an examinee's true score would fall 95 out of 100 times on repeated assessments.

REVIEWING THE ADEQUACY OF A NORM GROUP

It is necessary to examine key characteristics of a test's norm group to ensure the adequacy of the norms, hence, the appropriateness of the test. Manuals that come with commercially developed tests should provide this information. According to Salvia and Ysseldyke, some of the important characteristics of a test's norm group are: a) the representativeness of the group, b) the number of individuals in the group, and c) the relationship of the norms to the purpose of testing. Adequate representation is dependent, in part, upon the demographic characteristics of the individuals in the norm sample, including their age, sex, race/ethnicity, parent education level, and geographic location. It is important that the sample of individuals in the norm group be proportioned across the aforementioned variables according to their prevalence in the reference population.

For example, the norm group of an intelligence test developed in the United States for children ages 6 years, 0 months to 16 years, 11 months, should include representative proportions of children within this age range according to selected demographic variables based on U.S. Bureau of the Census data. The age of the norms (i.e., the difference in time between the year in which the norm group was administered the test and the year an examinee is administered the test) is also a critical dimension when evaluating the representational aspect. In order for a norm group to be representative, it must be current. Reschly suggests that test norms older than 10 to 12 years may lead to inflated test scores, based on research indicating that intelligence in the general population

increases at a rate of approximately three points per decade. The test consumer should be aware that the older the norm group is, hence, the older the test norms are, the less accurately the group and norms represent the current reference population.

The number of individuals comprising the norm group is also important because a large norm group assures reliability of the test as well as representation of outliers in the reference population. Salvia and Ysseldyke recommend that the norm group should contain at least 100 subjects per age or grade level. Also of crucial significance is the relationship of the norms to the purpose of testing. For example, if the purpose of testing is to determine how a child performed on a school district reading assessment, the norms developed for the district for that particular test administration would be the most appropriate reference of comparison. If the purpose is to ascertain how a child is performing intellectually, then the norms of a nationally standardized test of intelligence would be the most appropriate reference of comparison.

Finally, norms that include the performance of individuals with special needs are an important consideration for accurate representation, particularly when evaluating individuals for eligibility for special education services and program placement. To the extent that test norms are adequate, they allow for meaningful comparisons and accurate information about the population. The Standards for Educational and Psychological Testing (AERA et al., 1999) states: "Norms, if used, should refer to clearly described populations. These populations should include individuals or groups to whom test users will ordinarily wish to compare their own examinees" (p. 55). To this end, test users must determine the applicability of a test to any given individual or group.

STRENGTHS AND WEAKNESSES OF NORM REFERENCED TESTS

Ornstein describes a number of strengths of NRTs, including but not limited to the following: a) they assume statistical rigor in that they are reliable (i.e., dependable and stable) and valid (i.e., measure what they are reported to measure); b) the quality of test items is generally high in that they are developed by test experts, pilot tested, and undergo revision prior to publication and use; and c) administration procedures are standardized and the test items are designed to rank examinees for the purpose of placing them in specific programs or instructional groups. Stewart and Kaminski report that local norms, based on the test performance of students from a specific locale, have the added advantage of providing meaningful information regarding average performance, for example, in a particular school or school district. These authors report many other advantages of using local norms, including

that they decrease the likelihood of bias in educational decision-making because a student's test performance is compared to other students whose demographic and background factors are similar. In addition, they afford school systems the opportunity to compare data on students' educational outcomes to instructional curricula to which students have already been exposed. Furthermore, local norms are useful in facilitating decisions such as identifying the educational needs of students, determining standards for student progress, and identifying and making decisions about students' eligibility for Chapter I, English as a Second Language, and academically gifted programs. Finally, these norms are useful for identifying students at risk for school failure.

The predominant criticism of NRTs is that their content is seldom aligned with curricular content taught in educational settings (with the exception of locally normed tests). Good and Salvia refer to the match between the items on a norm-referenced achievement test and the content taught in a curriculum as content validity. The underlying assumption of content validity is that the items on a NRT should correspond to the content of the curriculum taught in a classroom. Results of a NRT devoid of content validity make it difficult to determine effective interventions that are needed for a student experiencing academic and/or behavioral challenges. Also, NRTs do not allow for monitoring academic progress over an extended period of time; instead, they provide an index of achievement or performance in comparison to a norm group at one specific point in time. Furthermore, an underlying assumption of NRTs is that examinees have had opportunities to acquire skills and experiences comparable to those of examinees in the norm group.

If disparities exist between examinees and the norm group in terms of skills and experiences, the conclusions based on the examinee's test performance may be misleading. "When a child's general background experiences differ from those of the children on whom a test was standardized, then the use of the norms of that test as an index for evaluating that child's current performance or for predicting future performances may be inappropriate" (Salvia & Ysseldyke, 1991, p. 18). This potential problem is tied to the issue of cultural fairness, which has been the subject of significant consideration in test development and research. Essentially, no test is completely culturally fair. The responsibility for school practitioners is to ensure that a child's level of acculturation (i.e., the extent to which an individual has adjusted to the culture in which he or she lives) is considered when choosing a NRT. Flanagan & Ortiz have done extensive research on acculturation and language differences in the assessment of diverse children, and they provide in-depth information and guidelines on this topic.

With respect to limitations of local norms, Stewart and Kaminski cite misinterpretation as a primary disadvantage. Like the point made by Salvia and Ysseldyke, the group to whom a child's performance is compared should be well-defined (e.g., the age and grade of the students comprising the reference group as well as the size and stability of the group). Also, information about the measures administered to students as well as how the scores were derived should be provided. Stewart and Kaminski emphasize that the knowledge of how a student's performance in a particular subject area using local norms compares with that of their performance using national norms is quite significant. For example, a child may perform in the High Average tier of the local norm group in a particular subject area yet perform in the Below Average tier when tested on a nationally normed test in the same subject area. To report how the child performed only in relation to the local norms would be misleading.

THE STATUS OF NORM REFERENCED TESTING

In part, due to the shortcomings of NRTs, other types of assessments are used to assess individuals' aptitudes and abilities. Such methods include Curriculum Based Measurement (CBM) as articulated by Shinn; the Dynamic Indicators of Basic Early Literacy Skills (DIBELS) as described by Good, Gruba, and Kaminski; and Curriculum Based Assessment (CBA) as described by Gravois and Gickling. Collectively, these methods use curriculum materials as the basis for assessing and monitoring students' academic progress. CBM and DIBELS assessment results are linked directly to instructional interventions, whereas CBA is used primarily to assess and modify a student's instructional environment for the purpose of placing the student in the most appropriate curriculum.

The Individuals with Disabilities Education Improvement Act passed in 2004 allowed states, for the first time, to use a student's response to scientific, research-based interventions as a basis for determining eligibility in the Specific Learning Disability (SLD) category of special education programs. This procedure, commonly referred to as Response to Intervention (RTI), is a significant shift from the traditional ability-achievement discrepancy model used in determining SLD eligibility. Although states have the option to continue using the ability-achievement discrepancy model, RTI, undoubtedly, will decrease the role of NRTs in qualifying students as learning disabled. Be that as it may, it is indisputable that NRTs facilitate meaningful comparisons between a student's test performance and that of the student's same-age peers in a test's norm group, and they will continue to be used and valued in the general education and special education arenas. It is also evident that CBA, DIBELS, CBM, and RTI procedures play a

significant role in instructional decision making and in the early 2000s were gaining an increasing role in special education eligibility decisions. Using a combination of these two assessment paradigms may well be the optimal solution for serving the educational needs of all children.

NORMAL DISTRIBUTION

The normal distribution is a widely used statistical tool. The normal distribution is often referred to as a *bell curve*, given its bell-type shape and perfect symmetry. The normal curve

represents a distribution of individuals and generally indicates that most individuals are typical or normal on a particular measurement, but some individuals differ from that norm; as one moves further and further away from the center of the normal curve, individuals tend to exhibit characteristics that are more atypical of the norm. Normal distributions describe many phenomena. A normal distribution also is a fundamental mathematical assumption of many commonly used statistical techniques. The normal distribution can be used for many purposes, including calculating probabilities, examining students' performance on tests relative to the performance of other students, determining when certain students' scores are unusual or highly atypical, and deriving common metrics to compare students' scores across a variety of different assessments. The normal curve is the basis of many commonly used educational measures, including the SAT, the GRE, and many commonly used intelligence tests.

Many of the variables that are studied by educational researchers are assumed to come from a population of scores that are distributed normally. The normal distribution first was discussed by de Moivre in the 1700s; however, the normal distribution did not begin to be used as a statistical tool until mathematicians such as Pierre-Simon Laplace (1749–1827) and Carl Friedrich Gauss (1777–1855) began to study the distribution (Walker, 1934). The basic idea underlying the normal distribution is that as one examines large samples of individuals, the distribution of those individuals on many characteristics will often (but certainly not always) approximate a normal distribution. This is because most individuals will be typical or in the middle on the curve, whereas there will be fewer individuals who will be either extremely low or high on any given measure.

To start with a concrete example, imagine a distribution of SAT scores for first year students at a particular university. Most students will receive scores that are near the mean (and the median, and the mode), which would be displayed in the middle of a normal distribution. However, there are a few students who score extremely high (e.g., a perfect score of 800), and a few students who score extremely low on the SAT; those students' scores would be expressed at the extreme ends or *tails* of the normal distribution. This same type of curve would be evident for many other samples (e.g., the weight of bumblebees, the height of elephants, the number of barks emitted per day by pet dogs, IQ scores of third graders, etc.). In all of these cases, most measures will hover near a mean score, some will differ slightly from the mean, and there will always be a few cases that will be extremely low or high.

MEASURES USED TO ASSESS NORMALCY

Although the normal distribution is often what people expect to see, many distributions turn out not to look

exactly like a perfect bell curve. There are a number of criteria that can be used to assess the normality of a curve. The criteria often provide information regarding how much a particular distribution differs from a normal distribution.

First, distributions can be skewed. A distribution is skewed when the mean of a sample differs from the median. When the mean exceeds the median, a distribution will be positively skewed, or skewed to the right; when the mean is less than the median, the distribution will be negatively skewed, or skewed to the left. A skewed distribution is one that contains extreme scores at either end of the distribution; this causes one tail of the curve to look as if it is stretched outward. For example, if a researcher examined a distribution of family income in a particular neighborhood where a billionaire lived, then the distribution would be positively skewed, because this one extremely high income would affect the shape of the distribution by literally *pulling* the distribution to the right by affecting the mean. Statisticians often indicate the level of skewness with a numerical value; a curve with a skewness of zero is a perfect normal distribution; in contrast, a curve with a skewness greater than or equal to ± 2.0 is quite highly skewed. A positive skewness value indicates that the distribution is skewed to the right (i.e., the mean is larger than the median), whereas a negative skewness value indicates that the distribution is skewed to the left (i.e., the mean is smaller than the median).

Second, distributions also can be described in terms of their kurtosis. The term *kurtosis* refers to how flat or peaked a curve is. In terms of kurtosis, the normal curve is mesokurtic (i.e., neither too peaked or flat). In contrast, distributions that are rather flat and have high standard deviations are referred to as platykurtic distribution, whereas distributions with a thin, tall center and a low standard deviation are referred to as leptokurtic distributions. A platykurtic distribution might occur when there is a large amount of variability in a measure (e.g., scores on an achievement test in a particular school vary greatly, from some very low scores to some average scores to some very high scores); in contrast, a leptokurtic distribution might occur when there is little variability in a measure (e.g., scores on an achievement test for most students in the school were all very close to each other, with little variability).

INTERPRETATIONS OF THE NORMAL CURVE

The normal curve is generally measured in standard deviation units, most commonly referred to as z-scores. The normal distribution has a mean z-score of zero and a standard deviation of 1.0. A z-score for any individual can be determined by subtracting the mean score of the

Normal Distribution

distribution from the individual's specific score and then dividing by the standard deviation of the distribution.

One of the most interesting mathematical features of the normal curve is that the percentage of scores that fall within certain areas under the curve are consistent across all normal distributions. Mathematically, exactly 34.13% of the area under the normal curve falls between the middle of the curve (which is also the mean, median, and mode), and one standard deviation above the mean (or one z-score above the mean); similarly, exactly 34.13% of the area under the curve also falls between the middle of the curve and one standard deviation below the mean. The percentage of area under the curve decreases as the number of standard deviation units one moves away from the mean increases. Thus an additional 13.59% of the area under the curve falls between both +1 and +2 standard deviations above the mean, and -1 and -2 standard deviations below the mean; an additional 2.15% of the area under the normal curve falls between ± 2 and ± 3 standard deviations above and below the mean (Sprinthall, 1997). The percentages of the area under the curve continue to remain identical on both the left and right-hand sides of the normal distribution as one proceeds up through higher standard deviations (z-scores). The exact percentage of area under the normal curve between any z-score and the mean can be determined by using a z-score table, which can be found in most introductory statistics text books.

Normal curves are also related to percentile scores, which are commonly used by many educational practitioners. This is particularly important, because educators often need to report and interpret individual students'

test scores for parents. A percentile is the point in a distribution below which a certain percentage of scores fall; thus a student who scored in the 60th percentile on an examination scored higher than 60% of the students who took that examination (this does not mean that the student correctly answered 60% of the questions on the examination). On a normal distribution, the 50th percentile corresponds with the middle of the curve, or a z-score of zero. When z-scores are positive, percentile measures will be above 50, whereas when z-scores are negative, percentile measures will be below 50.

Some other scores that are typically used in the field of education also can be expressed in terms of normal distributions. One of these is T scores, which have a mean of 50 and a standard deviation of 10; another is a stanine score, which divides the normal distribution into nine distinct units. Thus a mean T score (50) corresponds to the 50th percentile, to a z-score of zero, and to a stanine score of 5.

O

OBJECTIVE TEST ITEMS

An objective test item is defined as one for which the scoring rules are so exhaustive and specific that they do not allow scorers to make subjective inferences or judgments; thereby, any scorer that marks an item following the rules will assign the same test score. Objective tests began to be used early in the twentieth century as a means of evaluating learning outcomes and predicting future achievement, and their high reliability and predictive validity led to the gradual replacement of the essay test.

One common misconception about the objective test item is that it is limited to testing specific, often trivial, factual details, which would sometimes lead to the use of an essay or performance test to assess students' comprehension of broader principles or their ability to apply them. However, as Robert Ebel pointed out, well written objective tests (especially multiple choice tests) can actually assess such higher-order abilities to some extent. While it is true that some types of knowledge or abilities cannot be assessed by objective tests, educators also should keep in mind that what test items can assess depends largely on the skills and effort of the test constructor, rather the test format per se.

OBJECTIVE TEST FORMATS

A variety of different types of objective test formats can be classified into two categories: a selected response format, in which examinees select the response from a given number of alternatives, including true/false, multiple choice, and matching test items; and a constructed response format, in which examinees are required to produce an entire response, including short answer test items. This distinc-

tion is sometimes captured in terms of recognition and recall. These two general categories are further divided into basic types of objective tests, illustrated in the following examples (Figure 1).

The true/false test is the simplest form of selected response formats. True/false tests are those that ask examinees to select one of the two choices given as possible responses to a test question. The choice is between true and false, yes and no, right and wrong, and so on. A major advantage of the true/false test is its efficiency as it yields many independent responses per unit of testing time. Therefore, teachers can cover course material comprehensively in a single test. However, one apparent limitation of the true/false test is its susceptibility to guessing. It should be noted, however, that test givers can attenuate the effects of guessing by increasing the number of items in a test. In addition, some guessing might reflect partial knowledge, which would provide a valid indication of achievement.

Another selected response format type is the multiple-choice test, which has long been the most widely used among the objective test formats. Multiple-choice test items require the examinee to select one or more responses from a set of options (in most cases, 3-7). The correct alternative in each item is called the answer (or the key), and the remaining alternatives are called distracters. Examinees have less chance of guessing the correct answer to a multiple-choice test question compared to a true/false test question. In addition, the distracter an examinee selects may provide useful diagnostic information.

Related to the multiple-choice test is the matching test, which consists of a list of premises, a list of responses, and

Examples of objective test items

directions for matching the two. Examinees must match each premise with one of the responses on the basis of the criteria described in the directions. A major strength of the matching test is that it is space-saving and, therefore, can be used to assess several important learning targets at once.

A typical example of a constructed-response format is the short-answer test, which asks examinees to supply a word, phrase, or number that answers a question or completes a sentence. Sometimes it is called a completion or fill-in-the-blank test. Although what a short-answer test item can assess is generally more limited to factual information, it does not require the development of plausible distracters. Moreover, short-answer items are much less susceptible to guessing than selected-response format items.

HOW TO CONSTRUCT OBJECTIVE TEST ITEMS

Basically, scoring objective test items is easy: It only requires one to follow the scoring rules. However, constructing good objective test items requires much more skill and effort. The first step is to develop a set of test specifications that can serve to guide the selection of test items. A table of specifications (or test blueprint) is a useful tool for this purpose. This tool is usually a two-way grid that describes content areas to be covered by the test as the row headings and skills and abilities to be developed (i.e., instructional objectives) as the column headings (Figure 2). After specifying the content and ability covered by the test using the

table of specifications, the appropriate test item format is selected for each item. At this point, not only objective test items but also other types of test items—essay test or performance assessment—should be considered, depending on the learning outcomes to be measured.

The next step is to create specific test items. Typically, it is particularly important for objective test items to be written in clear and unambiguous language to allow examinees to demonstrate their attainment of the learning objectives. If complex wording is used, the item simply reflects reading comprehension ability. It is also important for each objective test item to focus on an important aspect of the content area rather than trivial details. Asking trivial details not only makes the test items unnecessarily difficult, it also obscures what the test constructor really wants to measure. Similarly, relatively novel material should be used when creating items that measure understanding or the ability to apply principles. Items created by copying sentences verbatim from a textbook only reflect rote memory, rather than higher-order cognitive skills.

Many other specific rules exist for constructing objective test items. Test constructors must be very careful that examinees with little or no content knowledge cannot arrive at the correct answer by utilizing the characteristics of the test format that are independent of specific content knowledge. Jason Millman and his colleagues called this skill of the examinees “test-wiseness.” For example, in multiple-choice test items, all options

Content areas	Skills and abilities			Total (%)
	Knowledge	Comprehension	Application, analysis, or synthesis	
1. Univariate analysis: Central tendency and variability	3	2	1	6 (24)
2. Bivariate analysis: Correlation and regression analysis	2	3	3	8 (32)
3. Statistical hypothesis testing: Concepts, methods, and interpretation	1	3	2	6 (24)
4. Comparison of means: Paired t-test and analysis of variance (ANOVA)	1	2	2	5 (20)
Total (%)	7 (28)	10 (40)	8 (32)	25

Figure 2 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

should be grammatically correct with respect to the stem (questions or incomplete statements preceding options), and key words from a stem, or their synonyms, should not be repeated in the correct option. Any violation of these rules would obviously provide an advantage for testwise examinees. Test composers should also equalize the length of the options of an item and avoid using specific determiners such as *all*, *always*, and *never* because some testwise examinees know that the correct option is frequently long and without such specific determiners. Robert Thorndike and Anthony Nitko have provided more comprehensive guidelines, with detailed explanations for constructing objective test items.

EFFECT OF OBJECTIVE TEST ITEMS ON TEACHING AND LEARNING

One common criticism of objective test items is that students are encouraged toward rote learning and other surface-processing strategies. Another related criticism is that objective tests, if used to evaluate the educational attainment of schools, encourage teachers to place undue emphasis on factual knowledge and disregard the understanding of students in the classrooms. Some evidence suggests that both are the case.

Kou Murayama, in a series of studies, investigated the effects of objective test items on the use of learning strategies. In one study, junior high school students participated in a history class for five days and took either an essay or short-answer test at the end of each day. Results showed that in the last day, those who took the short-answer tests used more rote learning strategies and fewer deep-processing strategies than those who took the essay tests. George Madaus reviewed much literature about the effects of standardized testing on what is taught at schools and found that teachers pay particular attention to the form of the questions and adjust their instruction accordingly, suggesting that objective tests could narrow instruction to the detriment of higher-order skills. Madaus argued that high-stakes tests

tests that are used to make important decisions such as the ranking of schools have much more influence on teaching.

However, educators should be reminded that objective test items are not limited to testing for specific factual knowledge. Well written items may not have such negative effects on students' use of learning strategies or teachers' teaching styles. Thus, it is not the objective test items per se that should be changed. What is important is to change the stereotypical beliefs that objective test items require only rote learning of factual knowledge and avoid poorly constructed objective test items.

OGBU, JOHN U(ZO) 1939–2003

John Uzo Ogbu was born in Nigeria on May 9, 1939. He earned a BA in anthropology at the University of California Berkeley in 1965, followed by an MA in 1969, and PhD in 1971. He taught at Berkeley from 1970 until

his death on August 20, 2003. His most influential contribution to education is his cultural-ecological theory, a grand theory explaining why some groups tend to experience low academic achievement and others do not. This work responds to other explanations for low minority group achievement such as cultural mismatch.

Cultural mismatch (also referred to as cultural discontinuity or cultural differences) suggests that minority students experience low academic achievement because some aspects of their cultures—language, dialect, perception of time and space, attitude toward collectivism and individualism—do not match the school culture. This mismatch puts them at a disadvantage compared to students who share cultural background with school teachers, text books authors, and standardized test writers. If cultural mismatch is powerful, asked Ogbu, why do immigrant minority groups such as Punjabis and Chinese that experience cultural mismatch and discrimination show relatively high academic achievement?

To answer this question Ogbu distinguished voluntary and involuntary minorities. Voluntary minorities are those who come to a society of their own choice, often through immigration. Involuntary minorities are those who come to a society through enslavement, conquest, or colonization. Voluntary minorities do not experience persistent or pervasive low achievement, whereas involuntary (castelike) non-immigrant minorities do. In the United States, Africans (like Ogbu) and Vietnamese are voluntary minorities, and African Americans and Native Americans are involuntary minorities. While Ogbu's theory focuses on Black academic disengagement and low achievement, it is intended as a theory of how voluntary and involuntary minorities fare in societies around the world.

According to his theory, involuntary immigrants experience a history of discrimination and prejudice that causes them to turn to each other in collective identity. If they know that they cannot turn to the dominant culture for help or support, they become more dependent upon and supportive of other members of their group. As they experience this fictive kinship, they also experience oppositional collective identity in which they reject behaviors and activities that represent the dominant, oppressor group. This pattern has been labeled "fear of acting White." Ogbu helped popularize, but did not invent, this label in an article that he co-authored with Signithia Fordham. According to Fordham and Ogbu, attitudes and behaviors that mark acting White include speaking standard English, listening to White music such as rock and roll or classical music, working hard in school, and getting good grades, which means students may actively undermine their own achievement in order to show solidarity with their group and to avoid feeling not truly Black.

Ogbu's theory has generated considerable research, commentary, and criticism. Criticisms include lack of attention to social class and gender, misuse of the term *caste*, and misconceptions regarding the social construction of race. Perhaps of most interest to educators, it has been criticized for blaming the victim. For example, in his last book (2003), about students in Shaker Heights, Ohio, he wrote that "Black students did not generally work hard" (p. 17) and "Black parents' educational strategies are not adequate and not effective in helping their children succeed in Shaker Heights schools" (p. 279). The theory has also been criticized because, while it purports to pay attention to history, it ignores historical facts about the avid pursuit of education by African Americans. Research generated by his theory, such as Bergin and Cooks (2002), showed that for some students, merely achieving high grades was not enough to elicit accusations of acting white. In addition, the theory has been criticized for not proposing solutions.

However, in his 2003 book, *Black American students in an affluent suburb: A study of academic disengagement*, Ogbu began to outline policy implications of his work. He suggested those policies will fail that do not address the community forces that foster underachievement. He was dubious about interventions such as school choice, cooperative learning approaches that capitalize on the assumption that Black and other minority groups value cooperation and collaboration, and culturally responsive education that supports cultural practices and learning styles allegedly common to African Americans. He wrote that they did not address community forces that foster avoidance of hard work. He recommended that schools implement minority achievement programs that reform community forces to support academic achievement. Such programs should demonstrate the link between schooling and adult futures, teach good study habits, and expose students to successful Black role models who thrived in school. The intent would be to create a collective identity that facilitates rather than undermines academic achievement.

OPERANT CONDITIONING

Operant conditioning is defined as the use of consequences to modify the occurrence and form of behavior. "To put it very simply, behavior that is followed by pleasant consequences tends to be repeated and thus learned. Behavior that is followed by unpleasant consequences tends not to be repeated and thus not learned" (Alberto & Troutman, 2006, p. 12). Operant conditioning is specifically limited to voluntary behavior, that is, emitted responses, which distinguishes it from respondent or Pavlovian conditioning, which is limited to reflexive behavior (or elicited responses).

Operant conditioning was developed by B. F. Skinner (1904-1990), a psychologist at Harvard University, in 1938, and has continued into the early 2000s to be a popular approach for influencing behavior. Although the model was originally applied to animal learning (rats, pigeons; Skinner, 1938; 1963), it was subsequently commonly applied in educational settings. The model involves the operations of positive reinforcement, negative reinforcement, extinction, response cost punishment, and punishment with aversives, each of which is described below in this entry.

ASSUMPTIONS RELATED TO LEARNING

Gredler (2005) offers the following assumptions as the foundation of operant conditioning:

Learning is behavioral change (meaning that observers conclude that learning has occurred when behavior changes).

Behavioral change (i.e., learning) is related to changes in environmental events (these events being precursors of and consequences of an action).

One can determine relationships between behavior and the environment only if the characteristics of the behavior and the experimental conditions under which it occurs are defined in physically observable terms and observed under controlled conditions (the process must be systematic, observable, and controlled).

The only acceptable sources of information about the causes of specific behaviors are data from the experimental study of behavior (people must observe both the behavior and its causes).

The appropriate data source is the behavior of the individual (rather than the observers' expectations or inferences).

Of prime importance in the operant conditioning model is the focus on relationships between environmental events and behavior defined in physical terms, with an avoidance of the use of *inner states* as explanations.

VARIATIONS OF THE MODEL

There are four contexts or types of operant conditioning: positive reinforcement, negative reinforcement, positive (or response-cost) punishment, and negative punishment (or punishment with aversives) (Landrum & Kauffman, 2006). The last three of these are all associated with aversiveness or aversive control while only one, positive reinforcement, is associated with positive control. Thus, researchers can distinguish between two variations of the model, a positive one and a negative one. (There is also extinction, which occurs when reinforcement following behavior is discontinued, causing the behavior itself to eventually be discontinued.)

In the positive version of the model, a person who emits a desired behavior (e.g., raising her hand and waiting to be called on) receives something good—a positive consequence (referred to as positive reinforcement). This may be a smile or praise or a piece of candy. The result of the reinforcement is that the behavior is strengthened, that is, its likelihood of subsequent occurrence increases. This represents a positive form of control.

In the negative version of the model there are three possible consequences. One is to avoid something bad—negative reinforcement. If a student raises her hand and waits to be called on, rather than speaking out, there is no positive consequence, only the avoidance of a negative one. A second is to receive something bad—punishment with aversives—which may take the form of being yelled at or ridiculed, hence reducing the tendency to speak out (or,

perhaps, just suppressing it temporarily). The last negative approach, response-cost punishment, represents being deprived of something good, that is, a previously earned reinforcer being removed because of an undesirable behavior such as talking out in class, rather than raising one's hand and waiting to be called on (Walker, Shea, & Bauer, 2004). The punishment might be being placed in time-out or sent to the principal's office. These three approaches all represent aversive control, which may be associated with anxiety and fear (Skinner, 1953), and they may not result in a diminution of the strength of the undesirable response.

Another variation of the model is based on who or what precedes or occasions a response. After repeatedly pairing a response with a stimulus that precedes it, called a discriminative stimulus (S^D), the response will only occur in the presence of S^D , not in its absence. Such a response is said to be under stimulus control. "A behavior under stimulus control will continue to occur in the presence of the S^D , even when reinforcement is infrequent" (Alberto & Troutman, 2006, p. 306). Examples of stimulus control are answering telephones only when they ring (the sound of the ring serving as a discriminative stimulus), driving through intersections when the light is green (the S^D), not when it is red (although this is an imperfect S^D , because drivers often run red lights), and paying attention in class (a response) when being watched by the teacher (an S^D).

COMPONENTS AND ACTIVITIES OF THE MODEL THAT AFFECT EDUCATIONAL OUTCOMES

Various different positive reinforcers can be used to increase the likelihood of desired behavior in the classroom. They appear in the form of (a) consumable (e.g., candy), social (e.g., praise), (b) activity (e.g., time on the computer), (c) exchangeable (e.g., points or stickers), and (d) tangible (e.g., getting to sit in one's favorite chair). Activity reinforcers are among the most educationally relevant, since the activity can be done with educational value such as doing a jigsaw puzzle or watching an instructional video. However, it is of critical importance that the desired behavior immediately precede the activity reinforcer rather than follow it in order for the reinforcer to strengthen the response (this is called the Premack Principle, after David Premack, its discoverer), and in some cases this may be difficult to arrange, as, for example, when the activity reinforcer is a field trip (Kazdin, 2001).

Various reinforcement schedules (Skinner, 1969) have an effect on educational outcomes by affecting the likelihood of a particular response. A continuous reinforcement schedule, wherein every occurrence of a desired operant response is followed by a reinforcement, is desirable when operant conditioning is first taking place. However, once the desired response occurs on a regular basis, it

can be maintained by only occasional or intermittent reinforcement, thereby lessening the load on the teacher.

There are four possible intermittent reinforcement schedules: fixed ratio, fixed interval, variable ratio, and variable interval. In an educational setting (as in most settings), the two variable schedules best maintain the desired behavior, primarily because of their unpredictability. For example, if students were given the opportunity to listen to music, a reinforcement, after handing in some number of completed assignments, they would be more motivated to hand in completed assignments if the number required was not always the same (variable ratio) or the time during which they had to be handed in was not always the same (variable interval). By comparison, in the fixed interval schedule, where the reinforcement is provided after the desired behavior has been performed for a fixed amount of time (say 10 minutes), it does not take students long to realize that they can do nothing for nine and a half minutes and then perform the behavior to get the reinforcement. Similarly, if the fixed ratio is 4:1, students will perform the behavior four times in a row, and then relax after receiving the reinforcement.

Operant conditioning is a vehicle for teachers to achieve behavior modification in order to improve classroom management and facilitate learning. There are three techniques employed in particular to facilitate learning: prompting, chaining, and shaping. Prompting involves giving students cues (called *discriminative stimuli* in the lexicon of operant conditioning) to help them perform a particular behavior. When students are learning to read, a teacher may help them by sounding out a word (just as when actors forget their lines, someone prompts them by saying their next line). Prompting helps to make the unfamiliar become more familiar, but, if used too often, students can become dependent on it, so teachers should withdraw prompts as soon as adequate student performance is obtained (a process called *fading*). Also, teachers should be careful not to begin prompting students until students try a performing task without extra help.

Learning complex behaviors can also be facilitated through an operant conditioning technique called *chaining*, a technique for connecting simple responses in sequence to form a more complex response that would be difficult to learn all at one time. Each cue or discriminative stimulus leads to a response that then cues the subsequent behavior, enabling behaviors to be chained together. Skinner taught pigeons to steer torpedoes toward enemy vessels in World War II by chaining together responses that adjusted the direction of a torpedo relative to the target as it appeared on a screen. Although the technique was not actually used in the war, it appeared in trial runs that it would work successfully.

The third, and perhaps most generalizable technique is called *shaping*, a process of reinforcing each form of the behavior that more closely resembles the final version. It is used when students cannot perform the final version and are not helped by prompting. Shaping involves gradually changing the response criterion for reinforcement in the direction of the target behavior. If the student is given 10 math problems, for example, and gets three of them right, the student gets a reinforcement. On the next set of problems, the student needs to get six right for a reinforcement, then 10. By shifting the criterion for reinforcement, or successive approximations, a student's behavior is shaped in the direction of ultimate success.

According to Landrum and Kauffman, "Despite a rich history and extensive empirical underpinnings, the behavioral perspective on teaching and management is not highly regarded in the education community" (2006, p. 47). Its critics contend it is an unfeeling approach more suited to animals than to humans (Landrum & Kauffman, 2006). Nevertheless, operant conditioning is commonly used in classrooms and is viewed by many teachers as an effective approach to improving classroom practice. It provides teachers with a set of tools for improving classroom management and student learning.

OPPORTUNITY/ ACHIEVEMENT GAP

Among the wide-ranging challenges facing American educators, perhaps no issue is more pressing than the inequity in student achievement among racial/ethnic and socioeconomic groups—a problem that in the early 2000s is somewhat contentiously referred to as the achievement gap.¹ Since the early 1970s, analyses of nationally representative survey data have documented a persistent history of achievement differences, according to which Whites and especially east Asians enjoy relatively high average student performance while African Americans and some Hispanic subgroups experience relatively low average student performance. Moreover, children whose families are on the lower rungs of the social class ladder average far lower achievement and educational attainment levels than their wealthier counterparts. Thus, it is important to recognize that what is often characterized as a single gap between White students and all minority students is more accurately portrayed as multiple gaps between and within racial and social class groups.

However gaps are measured—whether by pre-school vocabulary, elementary school grades, middle school standardized test scores, or high school or college completion rates—the fact that there is a continuing history of race and social class differences in U.S. education is not debatable. Perhaps the best evidence comes from the National Assessment of Educational Progress (NAEP), widely known as the nation's report card. NAEP trend data demonstrate persistent, if somewhat fluctuating, racial test score gaps going back to 1971. Although Black-White and Hispanic-White gaps in mathematics and reading steadily narrowed between 1971 and 1988, trends toward test score convergence reversed in the late 1980s. Some gaps stabilized and others actually widened throughout the 1990s. Since 1999, however, Black-White and Hispanic-White math and reading test score gaps have held fairly constant across age groups—with the exception of slight convergence in the Hispanic-White math gap and the Black-White reading gap among 9-year-olds. This convergence is trumpeted by the U.S. Department of Education as evidence of the impact of the No Child Left Behind Act (NCLB) of 2001.

Figure 1 presents cross-sectional analyses of fourth and eighth grade students' mathematics and reading results from the 2007 main NAEP.² Whites and Asian Pacific Americans score above national averages at both grade levels. Asian fourth grade students exceed the national math mean by .48 standard deviations (.50 SD approximates one year of academic growth) outperforming by .19 SD their White counterparts who also score above the national average. African Americans and Hispanics score below the national average in fourth and eighth grade. The math gap is especially pronounced for

Figure 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

African Americans (.61 SD below the mean), whereas Hispanic students score approximately .46 SD below the national average in mathematics and reading at both grade levels.

While standardized achievement data reveal students' relative mastery of specific knowledge and skills, still other data document differences in group-level educational attainment by alternate measures. For instance, according to the National Center for Education Statistics, high school dropout rates for Blacks and especially Hispanics substantially exceed those for Whites and Asians. Although the gap between Blacks and Whites narrowed significantly between 1965 and 2005, the disparity in the graduation rates of Hispanics versus other racial/ethnic groups persists at double-digit rates. The alarmingly high Hispanic high school dropout rate 1.4 million Hispanics between the ages of 16 and 24 were dropouts in 2005 (NCES, 2005) is in fact twice that of Blacks and more than three times that of Whites and Asians (see Figure 2).³ These numbers prefigure similar trends in educational attainment at the college level, as Hispanics are about half as likely as their non-Hispanic peers to complete four years of college (Vernez & Mizell, 2002).

Dramatic demographic changes in the United States only heighten the importance of these described gaps in

academic performance. Population trend data indicate that by 2025 fully one quarter of all U.S. K-12 students will be of Spanish-speaking origin. At the same time the standards-based accountability movement in education, on the rise since the late 1980s and focusing especially on state assessments and K-12 test scores, has shone a bright light on unrelenting racial/ethnic and socioeconomic differences in academic performance. Many policymakers have redoubled their efforts (perhaps sometimes only symbolically) to achieve group-level equality of educational outcomes, if not inputs. Tellingly, the preamble to NCLB explicitly states the goal of eliminating test-score outcome gaps by the year 2014. In other words, during the first two decades of the 21st century, official interest in these described achievement gaps in American education may be at an all-time high.

MEASURING CONSEQUENCES

Policymakers are increasingly aware that the importance of closing gaps goes well beyond presumed links between improved minority student performance and improved job prospects for minorities. The moral and civic imperative to eliminate gaps is strong, but on a simply utilitarian rationale it can also be said that better educated students earn higher incomes, live healthier lives, pay

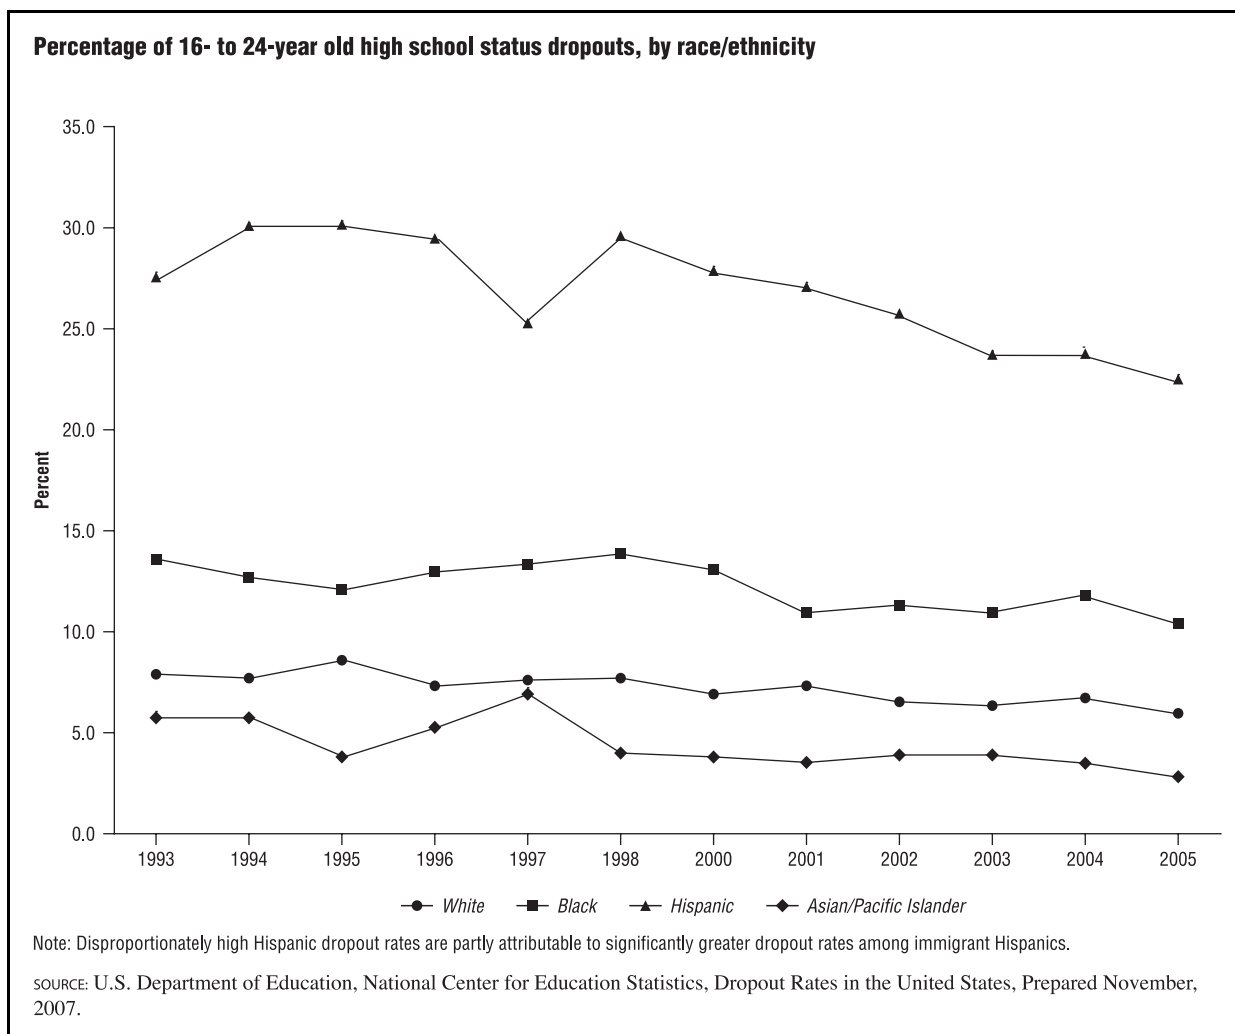

Figure 2 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

higher taxes, and are less likely to be involved in crime. Columbia University’s Henry Levin is a renowned researcher in the study of educational inequality and its costs. Working on the premise that high school graduation should serve as a minimal threshold for the standard of adequate education, he has investigated costs to society should educators fail to succeed in aiding greater numbers of students to procure a high school diploma. The report focuses on those individuals who at age 20 were not high school graduates in 2005, a group of approximately 700,000. The findings are sobering: For each of these individuals, over \$200,000 is lost to society in federal, state, and local tax revenues and costs to the public health and criminal justice systems over the lifetime of each dropout. When aggregated the fiscal consequences to society for this single group of 700,000 students who leave school without high school diplomas

is the staggering sum of \$148 billion in lost tax revenues and additional public expenditures over the lifetime. Clearly it is in the nation’s best interest to reduce dropout rates, particularly among non-Asian minorities, and to ensure that all children secure an adequate education (Levin et al., 2007).

GAPS EMERGE ON THE POLICY AGENDA

James Coleman was a sociologist at Johns Hopkins University when his controversial 1966 report to the U.S. Congress, *Equality of Educational Opportunity*, became the first national study to offer a systemic description of racial/ethnic differences in academic achievement among children of various ages. Prior to the Coleman Report, investigations of this nature had been focused on educational inputs: School effectiveness was measured by the resources that

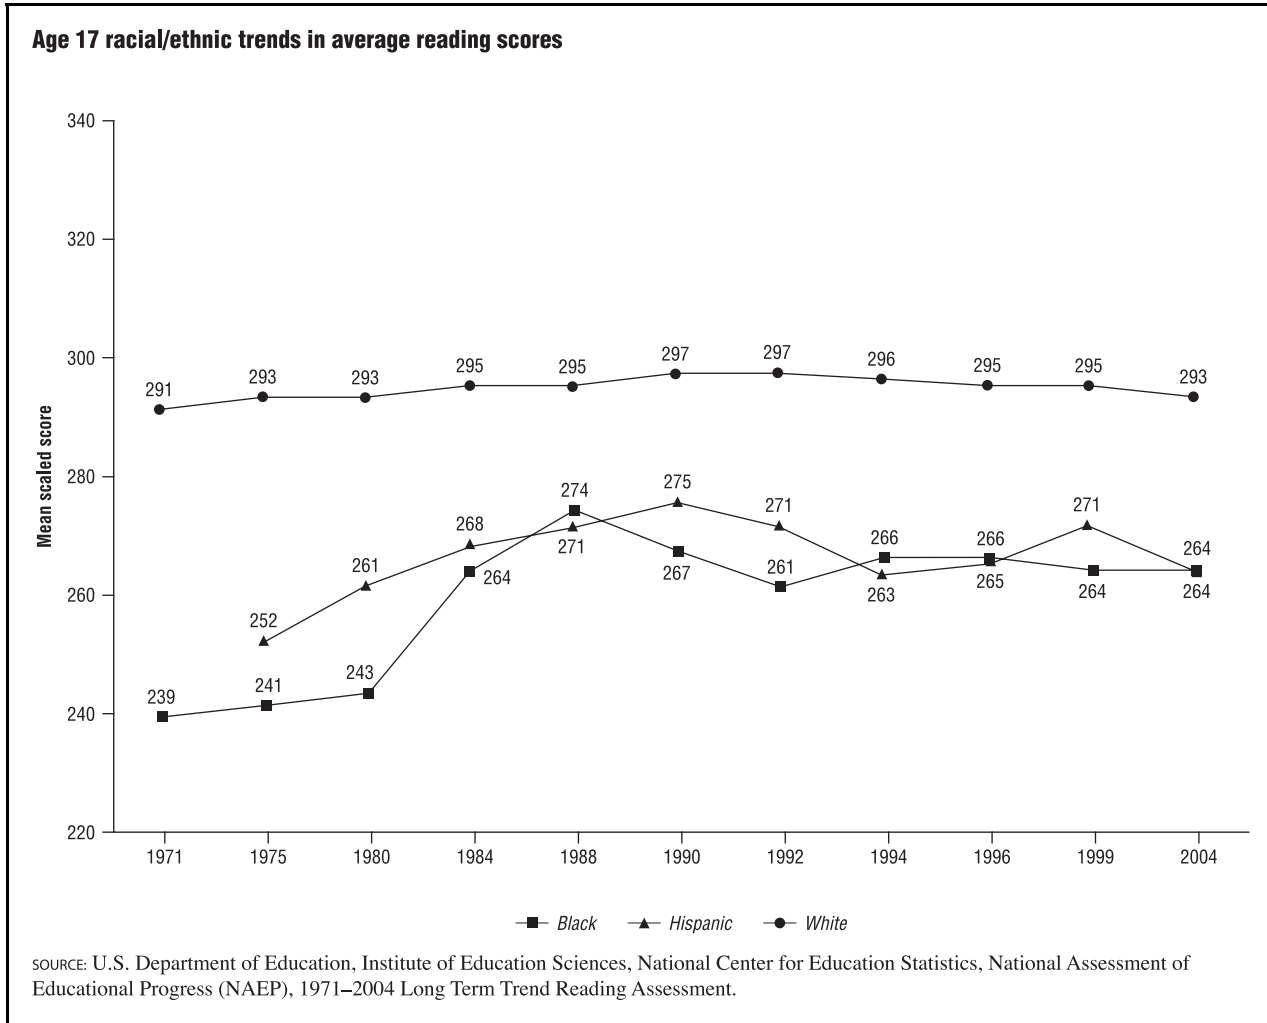

Figure 3 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

went into schools, not the quality of the students who came out of them. To his surprise Coleman found that (1) while schools certainly influence student achievement much of what tests measure must be learned in schools and (2) although school quality varies widely in the United States, the large documented differences in the quality of schools attended by Black and White children fail to explain most of the difference in average levels of achievement between Blacks and Whites (Rothstein, 2004). These rather controversial findings have been cross-examined by many researchers. Few, if any, dispute Coleman’s fundamental claims. Those who point to schools alone when searching for answers to stubborn outcome gaps may be ignoring the fact that children spend the vast majority of their waking hours each year somewhere other than the formal school setting. As developmental psychologist Urie Bronfenbrenner’s ecological systems theory emphasizes, children are

enveloped within families and they navigate social life with peers. They reside in neighborhoods and communities where schools are charged with their formal education, which takes place largely within individual classrooms. Each of these overlapping networks and domains conditions students’ educational performance in ways that are not mutually exclusive. Children lead nested lives.

Soon after publication of the Coleman Report, the federal government allotted substantial resources across multiple levels in an attempt to close the family/school/community input gap. In fact, desegregation in the wake of the 1964 Civil Rights Act combined with the Great Society’s War on Poverty programs (including Head Start and compensatory Title I funding) helped reduce glaring resource inequities and coincided with nearly 20 years of steady progress in reducing both the Black-White and Hispanic-White test score gaps since 1971, per Figure 3.

However, by the time U.S. Secretary of Education Terrel Bell released the landmark 1983 report to Congress, *A Nation at Risk*, concerns about inequality on the domestic front were pushed into the background, giving way to a growing preoccupation with educational efficiency and global competitiveness. Thus, targeted programs for the poor and compensatory education reforms were rolled back throughout the 1980s. By 1988 the progress in narrowing educational opportunity and achievement gaps had stalled.

The widening of test score gaps in the late 1980s went largely unnoticed until 1994 when experimental psychologist Richard Herrnstein and political scientist Charles Murray published *The Bell Curve* to much fanfare and subsequent controversy. Their conclusions about the genetic inevitability of the gap were deduced from the research of others and resurrected in particular the much disputed claims of education psychologist Arthur Jensen, which were first published in 1969 in the *Harvard Educational Review*⁴. When a special task force of the American Psychological Association reviewed the data used by Herrnstein and Murray the association arrived at a much different conclusion: The paucity of direct evidence of the Black-White differential in psychometric intelligence simply could not support the genetic hypothesis. Richard E. Nisbett, a professor of psychology at the University of Michigan, has charged the authors of *The Bell Curve* with having provided a “shockingly incomplete and biased” reading of the research (Nisbett, 1998, p. 96). As of 2008, what all psychologists agree upon is that a person’s developed capacity for intelligent behavior often differs in predictable ways from the person’s hereditary potential. So-called intelligence or aptitude tests measure the development of innate abilities. The collective research of American psychology leads one to conclude that environmental factors explain far more of the variance in achievement than the number of Blacks or Whites in a person’s family tree (Neisser et al., 1996).

SOURCES OF THE GAPS

When people turn to an examination, then, of contextual factors contributing to socioeconomic and racial education gaps, the breadth and depth of their sources quickly becomes apparent. Because causes are layered and overlapping, they are best considered simultaneously across domains. From a top-down structural perspective one might perceive broad economic conditions as being linked to, say, state and local tax rate policies that bear directly, if also differentially, upon community labor markets and housing values which, in turn, dictate school finance schemes. There are indeed sizeable gaps in educational resources that differentiate communities serving White and minority children. From a less structural, bottom-up perspective, concentrated on student effort and family

influence, one sees substantial variation in parents’ approach to child rearing. Whether children are talked at or listened to, how frequently they read and are read to, and whether or not they attend quality preschool and summer school are important factors that are conditioned by parents’ effort and resources. Children’s friends and peers pick up where families leave off, exerting increasing influence as students progress through schooling. In short, there is a dynamic and sometimes transformative relationship between the practices of real people including students, parents, and peers and the structures of school, society, and even history (Ortner, 2006).

Figure 4 shows a nested, albeit by no means exhaustive, depiction of the many structural and individual-level factors that have been examined to understand the causes of the gap. The embedded domains are not mutually exclusive categories. Rather, they are composed of related factors that act upon one another in complex ways that are often difficult to observe and quantify. One challenge, therefore, is to determine the extent to which the attributes of formal institutional settings and those of less formal student, family, peer group, and neighborhood and societal-level influences contribute to the gaps. A few of the better documented causes of these gaps are noted below.

Re-segregation and the Distribution of Teacher Quality.

In June 2007, a divided U.S. Supreme Court restricted the ability of public school districts to use race in determining which schools students can attend. Most voluntary desegregation efforts by school districts are now unconstitutional. According to Professor Gary Orfield of the UCLA Civil Rights Project, the re-segregation of U.S. schools has accelerated since the early 1990s and continues to grow in all parts of the country, most conspicuously among African Americans and Hispanics. Not since President Lyndon Johnson signed the Civil Rights Act have schools been as segregated as they are as of 2008. When people ask what it is about segregated schools that contributes to the racial achievement gap many point to course offerings, the composition of the student body, and perhaps especially the instruction gap. In a 1991 study of 900 Texas school districts, Harvard University’s Achievement Gap Initiative director, Professor Ronald Ferguson, found that nearly all of the school-level variation in the gap in achievement between Blacks and Whites was attributable to systematic differences in the skills of their teachers. The simple fact is that far fewer of the best prepared teachers are teaching in schools where the vast majority of students are Black and/or Hispanic. These disparities in access to high-quality teachers and teaching are large and growing worse (Darling-Hammond, 2007).

Although quality teachers are important, it is nevertheless the case that most of the group-level variation in student achievement outcomes can be attributed to factors

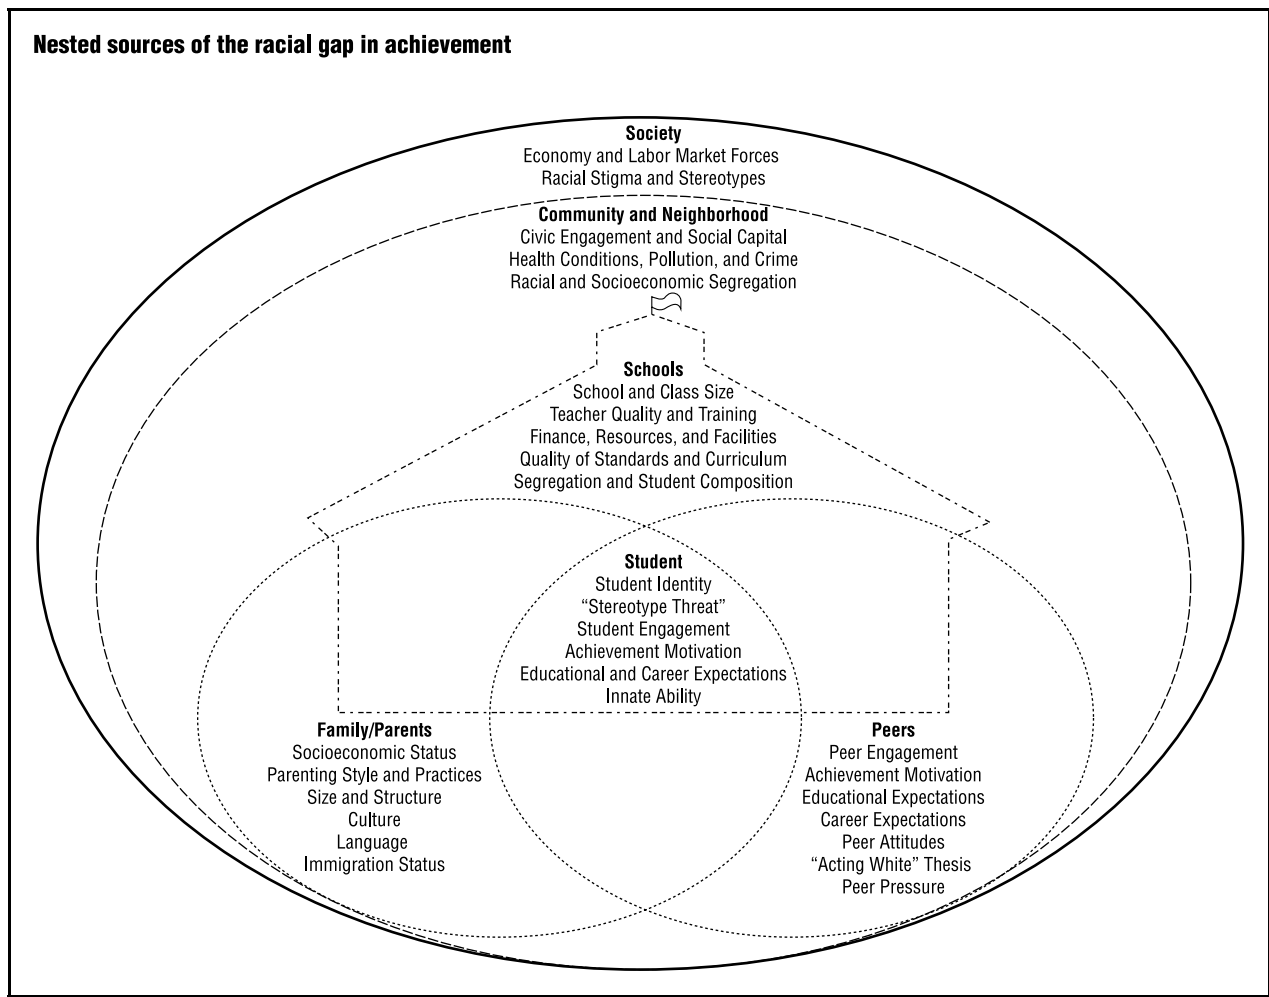

Figure 4 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

outside of schools. As findings based on and replicating the Coleman Report have time and again demonstrated, other structural conditions and individual-level factors apart from schools also affect gaps in achievement.

Socioeconomic Status and Parenting. Socioeconomic status (SES), a measure of parental education, employment, and income is among the most powerful predictors of student achievement. Many prominent social scientists have shown that the correlation between SES and race is inevitably linked to diminished access to quality education for underrepresented minorities, and thus, not surprisingly, to patterned racial inequality in educational outcomes. While only 7 percent of White mothers in the Early Childhood Longitudinal Study of the Kindergarten Class of 1998 1999 (ECLS-K) had failed to complete high school, a full 18 percent of Black mothers and 35 percent of Latina mothers had failed to do so. Likewise,

only 15 percent of White children (and 11 percent of Asians) under the age of 18 were living in poverty in 2005 compared to almost one-third of all Black and Hispanic children (NCES, 2006). Not only are Black and Hispanic children more likely to have parents who have not completed high school and are poor, but they are also more likely to attend schools with other poor children. To the degree that both family poverty and school poverty affect academic achievement, Hispanic and Black students are twice disadvantaged (Rumberger, 2007).

Some understanding of how SES influences achievement is provided by psychologists who study the interactions between parents and children. The research of psychologist Laurence Steinberg at Temple University indicates that a lack of school-specific knowledge and a lack of opportunity (good parenting takes a lot of time) are what differentiate high and low SES parents in their parenting styles and approaches to raising children (Steinberg, 1996).

Other research conducted by Betty Hart and Todd Risley, child psychologists at the University of Kansas, links children's language development to parents' communication style. In a well-known 1995 study, they found that by age 3 the children of professionals had vocabularies of about 1,100 words—the children of welfare parents had vocabularies of about half as many words as their peers not living in poverty. Comparing children's vocabulary scores with their home life, Hart and Risley concluded that children's vocabulary correlated most closely to the number of words the parents spoke to their child. In addition, the number and kinds of words that children heard varied markedly by social class. In short, early childhood parenting practices and communication styles matter greatly and are patterned along class lines.

To reiterate, only about one-third of the racial gap in achievement can be attributed to what goes on in schools. Moreover, emerging research consensus indicates that family socioeconomic status accounts for at least another one-third of the gap in educational outcomes (Hedges and Nowell, 1999). While the effect of schools on a child's academic achievement is near impossible to isolate from other influences (including family SES), many researchers agree that even eliminating vast resource differences between schools and among families would not entirely close the racial gap in achievement. In fact, one of the most perplexing aspects of the racial test score gap is its persistence among even middle-class students and among students at the top of the achievement spectrum—the very pool from which the nation's leaders are drawn (Jencks & Phillips, 1998).

Individual Identity and Stereotype Threat. The work of Stanford social psychologist Claude Steele helps to interpret the persistent achievement gaps even among students who are enrolled in the most competitive U.S. universities. In spite of the many obstacles that inhibit educational achievement among non-Asian minority students, many forge ahead to attain high levels of academic success. Some minorities within the academic vanguard, however, may encounter further achievement barriers corresponding to their relative identification with schooling. In his groundbreaking work on how stereotypes interact with students' identities to shape educational performance, Steele (1997) explains what he calls "stereotype threat." According to Steele, stereotype threat arises when school-identified African Americans are in a situation or doing something for which a negative stereotype about one's group applies and must therefore be disconfirmed. Thus, stereotypes become particularly threatening for those who associate their identity and self-worth with success in a domain where their own group has been obviously stereotyped. So above and beyond the K-12 instruction gap and the socioeconomic inequality noted above, stereotypes

about groups can influence the identity formation and cognitive functioning of individual group members. The burden of heightened awareness about stereotypes and social stigma affects especially test score outcome gaps among students of color who are otherwise apparently advantaged.

SOCIETY'S INTEREST IN ELIMINATING ACHIEVEMENT GAPS

The coincidence of dramatic changes in U.S. demographics and new information about gaps accompanying the standards movement has led policymakers to increase pressure particularly on schools to demonstrate annual progress in student achievement for all students. That achievement gaps and disproportionately high dropout rates among non-Asian minorities have re-emerged on the policy agenda may seem relatively unsurprising in light of research demonstrating that the average high school graduate pays nearly \$140,000 more in taxes over the course of a lifetime than a high school dropout. Baby Boomers whose overall well-being depends on the productivity of subsequent generations are concerned that the population base of American voters and taxpayers will increasingly come to be made up of persons less educated than they themselves were. Yet regardless of all researchers know about the incidence, consequences, and the causes of these gaps, government policy has only partially responded to this crisis. Even as most educational reform proceeds through almost entirely school-centered efforts to eliminate group-level achievement differences, the finding of the Coleman Report bears repeating: No more than 40% of the racial gap in educational outcomes can be attributed to the schools themselves (in isolation of other non-school factors). The ability to respond to the achievement gap problem will ultimately depend on whether people recognize and act on the broad range of factors that collectively shape student achievement.

NOTES

1. The very term "achievement gap" is considered by many to be a problematic misnomer. By reframing group-level differences in academic outcomes as the shameful product of a long history of discriminatory gaps in educational *inputs*, Gloria Ladson-Billings, in her 2005 presidential address to the American Educational Research Association, asserted that the so-called achievement gap is more accurately portrayed as an historically accumulated "educational debt" still owed underrepresented minority and poor students (Ladson-Billings, 2006).
2. Main NAEP data are not available for 12th graders in 2007.

Orthopedic Impairments

3. It should be noted, however, that Hispanics are also making real educational gains over generations improvements that are obscured by the continuing influx of new immigrants (Smith, 2003).
4. Jensen argued that programs like Head Start, which tried to boost the academic performance of minority children, were doomed to failure because I.Q. was so heavily genetic and impervious to environmental influences (Gladwell, 2007).

ORTHOPEDIC IMPAIRMENTS

Orthopedic impairments are the most common of physical disabilities. A physical disability is any condition that interferes with a student's ability to use his or her body. The term *physical disabilities* may be used interchangeably when referring to orthopedic impairments. In 2004 the U.S. Department of Education reported that 74,000 students between age 6 and 21 received special education services under the orthopedic impairments disability category.

ORTHOPEDIC IMPAIRMENT DEFINITION

According to the Individuals with Disabilities Education Improvement Act of 2004 (IDEA), orthopedic impairment is as follows: "a severe orthopedic impairment that adversely affects a child's educational performance. The term includes impairments due to the effects of congenital anomaly (e.g., clubfoot, absence of some member, etc.), impairments due to the effects of disease (e.g., poliomyelitis, bone tuberculosis, etc.), and impairments from other causes (e.g., cerebral palsy, amputations, and

fractures or burns that cause contractures)” (Pierangelo & Giuliani, 2007, p. 268).

Skeletal system impairments that involve the joints, bones, limbs, and associated muscles represent the musculoskeletal disorders. Orthopedic impairments often are divided into three main categories to help characterize the potential problems and learning needs of the students involved. These categories are neuromotor impairments, musculoskeletal disorders, and degenerative diseases. Although neuromotor impairments involve the central nervous system (brain, spinal cord, or nerves that send impulses to muscles), they also affect a child’s ability to move, use, feel, or control certain parts of the body. Clinically, they are separate and distinct types of disabilities with entirely different causes from musculoskeletal disorders, but they result in similar limitations in movement. Some examples of neuromotor impairments are spina bifida, cerebral palsy, and spinal cord injuries. Musculoskeletal disorders include defects or diseases of the bones and muscles, such as limb deficiency or clubfoot. Degenerative diseases are those that affect motor movement such as muscular dystrophy.

Orthopedic impairments involve a wide range of causes and a diverse group of students. Some children have impairments caused by congenital anomalies, whereas others have experienced injuries or conditions that have resulted in orthopedic impairments. Congenital causes include cerebral palsy, osteogenesis imperfecta, joint deformity, and muscular dystrophy. Motor vehicle accidents, sports injuries, premature birth, and other injuries and conditions may cause orthopedic impairments. Burns and broken bones can result in damage both to bones and muscles. Some children have their impairments from birth, while others acquire a physical disability, so age of onset varies widely. There does not appear to be any trend toward greater incidence of orthopedic impairment in boys or girls or based on cultural or racial factors.

Some children with skeletal deformities have surgery. Others have to use various types of braces, prosthetic, and orthotic devices before, after, or in place of surgery. Others may use adapted wheelchairs. Many children identified with severe and multiple disabilities have an orthopedic impairment that must be considered when assessing and establishing services.

ASSESSING ORTHOPEDIC IMPAIRMENTS

Evaluating children with orthopedic impairments can be complicated because there are so many different types of disabilities and causes of impairment. Most orthopedic impairments are identified before a child enters school, but sometimes they are missed or do not appear until a

later age. A teacher may notice signs of poor coordination, frequent accidents, or complaints of acute or chronic pain.

The assessment must include a thorough medical evaluation of the child’s orthopedic impairment by a licensed physician. Other data generally include documentation of observations and assessments of how the orthopedic impairment affects the child’s ability to learn in the educational environment, as well as observations concerning mobility and activities of daily living. It is important to assess a student’s social and physical adaptive behaviors through various checklists, inventories, rating scales, and interviews with those who know the child best. The severity of functional limitations must be such that they adversely impact the child’s education performance.

A social history supplements the medical history, as does basic screening information on hearing, vision, speech and language skills, and development in areas such as cognition and social/emotional, or self-help behaviors. A team approach is taken for assessment and recommendations. The team that assesses a child with an orthopedic impairment must involve a parent and at least one of the child’s general education classroom teacher(s). It should also include a licensed special education teacher, school counselor and/or psychologist, a licensed physician, and other profession personnel as appropriate. For example, a licensed physical therapist or occupational therapist should assess specific motor dysfunction in gross and fine motor development, neuromuscular development, daily living activities, sensory integration, and the need for adaptive equipment. The assessment also considers the permanent nature of the child’s impairment. Usually the condition will not be considered an orthopedic impairment if it is not going to last at least 60 days.

More than one test always should be used to evaluate a child’s needs for services. In all, the assessment must take into consideration the entire education from all angles, not just physical access to buildings, computers, libraries, or equipment that facilitates learning. For instance, a child may need to receive occupational therapy or other treatments, requiring time away from the general education classroom. Educators will need to develop adaptive strategies and adopt a hands-off approach at times to help students develop some independence. Then, too, social and peer issues also must be considered. The final evaluation should describe how the orthopedic impairment adversely affects a student’s areas of development.

CHARACTERISTICS OF CHILDREN WITH ORTHOPEDIC IMPAIRMENTS

Children with orthopedic impairments have a wide range of characteristics that are specific to the underlying diagnosis. Therefore, it is difficult, perhaps even impossible, to generalize about the students in this category. For

example, a child with a spinal cord injury could have immobility limited to one side of his or her body, just the arms or legs, or total paralysis. A child with cerebral palsy may have movement but need a wheelchair because he or she has slow, uncontrolled movements that make it difficult to walk.

It also is difficult to know prior to a thorough assessment, including input from medical professionals, what types of associated symptoms to expect. However, many students with orthopedic impairments have problems with motor skills, such as those involved in using standard writing tools, turning pages or books, or exploring and participating in typical classroom activities. Some students have associated speech impairments or multiple disabilities that may affect particular academic areas.

Some students with physical disabilities may lack common experiences and knowledge or common places, items, and activities as compared with general education students. This is due to a lack of mobility and, if their condition has existed since birth, the lack of typical childhood play and exploration. These students' social interactions often are limited because of limited motor, self-help, and self-care skills. Sometimes, standard instructional materials includes mention of objects and experiences or assumes comprehension that is beyond the experience and background of the child with an orthopedic impairment. Children with orthopedic impairments may have pain and discomfort, may sleep poorly and therefore be fatigued in class, and may be on medications. They also may miss school more frequently than other students because of their medical conditions.

Poor self-concept and poor self-advocacy skills may affect an individual student's performance or behavior. Some students with orthopedic impairments feel helpless or depressed as a result of their physical disability.

Some diseases, such as muscular dystrophy, are progressive, which means a child's need for services is likely to increase and certainly to change throughout the continuum of education. Other orthopedic impairments, particularly those caused by injury or temporary impairments from surgery, may lessen over time. Advances in medical care have allowed for better diagnosis and treatment of some disorders and diseases that cause orthopedic impairments. It is important to realize that some children with orthopedic impairments also face issues related to having both chronic and terminal illness.

EXAMPLES OF ORTHOPEDIC DISORDERS

More than 50 diseases and disorders are associated with orthopedic impairments. Along with subgroup types for these disorders. Spina bifida, scoliosis, cerebral palsy, and muscular dystrophy are some of the more well-known

conditions that cause orthopedic impairments in children. Spina bifida is a cleft spine, or incomplete closure of the spinal column. It is the most common permanently disabling birth defect. Spina bifida occulta is the mildest and most common form; next in severity is meningocele. With this type, the spinal cord develops normally, but the meninges, or protective covering, push through the opening in the vertebrae. Meningocele can be repaired surgically. Myelomeningocele is the most severe form of spina bifida. The bones of the spinal cord do not completely form and the spinal canal is incomplete, resulting in the spinal cord and meninges protruding out of the child's back. Spina bifida may be associated with hydrocephalus.

Scoliosis is a side-to-side curvature of the spine, measured by x-ray examination as greater than 10 degrees. It makes the shoulders, hips, or both appear uneven and can cause pain in the back. Most cases of scoliosis have no known cause, and although scoliosis can occur in children with other orthopedic impairments, it normally occurs in otherwise healthy children.

Cerebral palsy (CP) includes a number of chronic disorders that impair movement control. They appear early in life and generally do not worsen as children age. Cerebral palsy affects about 500,000 people in the United States; about 8,000 infants and 1,500 preschool-age children are diagnosed with it each year. Cerebral palsy is caused by injury to parts of the brain that control the ability to use muscles. The injury can occur before birth, during delivery, or soon after birth. Early signs normally appear by the time a child is 18 months of age. The three main types of CP are spastic, where muscle tone is too high or too tight; athetoid or dyskinetic CP, which can affect the whole body with slow, uncontrolled movements and low muscle tone; and mixed CP, a combination of the symptoms from both athetoid and spastic CP. A child with mixed CP has some muscles that are too tight and others that are too loose so that some movements are involuntary and mobility is limited in other areas by stiffness.

Muscular dystrophy (MD) is a group of genetic diseases characterized by progressive muscle weakness. The muscles most affected by MD vary, as do the types of the disease. Some are ultimately fatal, such as Duchenne muscular dystrophy, which also is the most severe form and the most common form affecting children. Although Duchenne MD results from a defective gene, it often occurs in families with no known history of the disease. Muscle weakness, rapid progression, and difficulty with motor skills are some of the characteristics of Duchenne MD. It primarily affects boys and symptoms usually begin in early childhood. There are several forms of muscular dystrophy, each with unique characteristics.

For example, Emery-Dreifuss MD typically causes symptoms in late childhood and early adolescence.

EDUCATIONAL PRACTICES

Several laws ensure an inclusive education for students with physical disabilities. The Individuals with Disabilities Education Improvement Act (IDEA) was introduced in 1975 and passed in 1990. It was reauthorized in 1997 and 2004 and includes provisions for children with orthopedic impairments as defined above. Students with orthopedic impairments also may be eligible for accommodations for general classroom inclusion under Section 504 of the Vocational Rehabilitation Act, passed in 1973. In addition, the Americans with Disabilities Act (ADA), which was passed in 1990, includes provisions concerning discrimination against individuals with disabilities and requirements that school facilities are accessible to all.

Placement is a key consideration for students with orthopedic impairments. The goal is inclusion in general education classes, but some students may need services from resource rooms, special classes, schools, or residential facilities, as well as hospital or homebound programs. In 2004, the U.S. Department of Education reported that about 46% of school-age children receiving special education services under the orthopedic impairments category were educated in general education classrooms. Setting up the appropriate placement, services, and environment begins with asking the student what he or she needs and evolves through the assessment and individualized education plan (IEP) process.

Students with orthopedic impairments may present unique challenges in adapting instructional environments that call for creative solutions. Some students may be paralyzed and require assistance moving from place to place. A student may require assistance with basic self-care such as toileting. These and other needs call on teachers to perform duties that historically have not been part of their role in school. Becoming familiar with orthotics, prostheses, adaptive devices, and the specific characteristics of a student's impairment can improve the experience for student and teacher.

To assist with academic tasks, a teacher might secure papers to a student's work area with tape, clipboards, or magnets; place rubber strips or pads on work tools such as rulers and calculators to help keep them from slipping during use; and provide writing instruments that require less pressure to produce a mark, such as felt-tip pens or soft lead pencils. Communication technology can assist the student and teacher in the classroom as well.

Specialists such as physical therapists and orthopedic therapists will be involved in the educational assessment and often will have ongoing involvement in the care of students with orthopedic impairment. States may have

specific qualification requirements for teachers who participate in special education programs for children with orthopedic impairments, including basic study of disabilities, anatomy, physiology, and therapeutic movement.

ASSESSMENT AND INSTRUCTIONAL ISSUES

The varying degrees and types of physical disabilities can present special challenges to those local schools and educators who instruct students with orthopedic impairments. Providing the least restrictive environment and promoting eventual independence for students with physical disabilities requires addressing each case specifically, working in a team approach with the student, parents, and education and health professionals to provide a plan that best meets the student's needs. It is important that the teacher can carry over techniques from these professionals into the classroom.

Alliance of state laws with IDEA is an important consideration. The team must consider all applicable laws and regulations in planning for the education of a child with a physical disability. This work includes testing of students under state and federal guidelines such as the No Child Left Behind (NCLB) Act, which was signed into law in 2002 by President George W. Bush. The act revised the Elementary and Secondary Education Act, which is the primary federal law in pre-collegiate education. NCLB requires annual testing of all students in reading and math proficiency.

The NCLB Act initially allowed up to 1% of special education students to take alternate tests; in 2005 the number was raised to 3%. Students may take alternative tests if they meet certain legal criteria. Several options are available, including having different achievement criteria or taking the regular assessment with approved accommodations or modifications.

P

PARENT INVOLVEMENT

Parental involvement in education and, its related term, family school relationships, have been conceptualized through multiple disciplinary lenses and through educational agency, as well as from local, state, and federal policy perspectives. Parental involvement in education and family school relations are terms that have been used interchangeably. However, there are subtle distinctions. Family-school relations are often conceptualized as the interactions, especially the communication, between families and schools pertaining to academic progress of students, academic or behavioral problems, and expectations for home engagement. This is the type of involvement that is often included in school policies pertaining to involvement. It is also evident in federal policies such as the No Child Left Behind Act, which defines parental involvement in education as “the participation of parents in regular, two-way and meaningful communication involving student academic learning and other school activities” (107th Congress, 2002).

More broadly, parental involvement in education has been defined as “parents’ interactions with schools and with their children to promote academic success” (Hill et al., 2004). Such interactions extend beyond the engagement with schools, to the home life and the expectations and values for education that are communicated directly and indirectly to children. These conceptualizations focus on individual students and their families. Other disciplines, such as economics, have defined it in a way that gives parental involvement a different focus or level of analysis.

Within the field of economics, parental involvement in education is often defined collectively across parents

within schools and across schools within districts, rather than at the individual or family level. Parental involvement has been conceptualized as “collective parental pressure” on schools or the impact of collective utilization of school policies such as school choice, exiting public schools and district assignments in favor of private, charter, and magnet schools (Epple & Romano, 1998; McMillan, 2000). Collective parental pressure can also occur through organized parent-teacher associations or simply through concerned parents monitoring the schools. It can impact school quality and climate and, in turn, school performance. In addition, economic conceptualizations include parental influence by voting for (or against) school board members, school district budgets (e.g., levies, bonds), and involvement in school governance and administration. These, in turn, impact school processes and learning outcomes (Jimenez & Sawada, 1999; Nechyba, McEwan, & Older-Aguilar, 1999). In addition to focusing on collective influence of parents, the outcomes of interest often are focused at the collective performance of schools or school districts, rather than individual students’ academic progress. The involvement of just a few parents may influence the quality of instruction in a classroom or a school and, thereby, influence the academic development of many students (McMillan, 2000).

There are at least three theories that have guided research and practice (Comer, 1995; Epstein, 1987; Grolnick & Slowiaczek, 1994). Each of these theories conceptualize parental involvement in education as a multi-dimensional construct that includes communication between families and schools, parental involvement in education at school (e.g., volunteering at school) and

parental involvement at home (e.g., helping with homework; providing educational experiences outside of school). Whereas these theories were based on elementary school contexts, additional research identifies appropriate types of involvement for middle and high school. For example, some theories distinguish involvement that reflects “academic socialization” such as communicating the importance or value of education and linking schoolwork to students’ interests or goals (Hill & Tyson, 2007) and “structural involvement,” which includes providing students with the space, materials and expectations for achievement that is especially important for adolescents (Chao, 2000).

Assessments of parental involvement vary widely across studies and typically reflect assessments from parent, teachers, and students’ perspectives. As research shows that these reports are often only moderately correlated with one another, their often unique relation with academic outcomes supports the premise that each reporter has a unique and important perspective (Reynolds, 1991). There are few “gold standard” measures of parental involvement and family school relations. However, most measures attempt to account for frequency of involvement, especially frequency of communication and parental visits to the school. Longer and more detailed measures attempt to account for who initiated contact. Initiation is important because parents and teachers tend to initiate contact for different reasons (Epstein, 1996). Teachers tend to initiate contact, beyond the regulated parent-teacher conferences, in the context of academic or behavioral problems. Parents, in contrast, tend to initiate contact for more proactive reasons and their initiated contact is positively associated with achievement.

DEVELOPMENTAL TRENDS

Beyond the variations in assessments of parental involvement, there are some consistent developmental trends in the normative levels of parental involvement in education. In general, parents tend to be more involved in their children’s education when the children are younger, especially in elementary school, than they are in middle and high school (Eccles & Harold, 1996; Stevenson & Baker, 1987). School transitions (i.e., school entry; middle school and high school transitions) mark times when parental involvement changes in amount or type. Schools may be more or less welcoming; parents may feel more or less efficacious about being involved. Despite lower mean levels of involvement in middle and high school, parental involvement in education remains positively associated with academic outcomes (Hill et al., 2004). However, the types of involvement that are most influential for adolescents are not accounted for in extant theories and measures of involvement and, thus, one can conclude

that parental involvement does not decline during middle and high school but changes form and shape (Hill & Taylor, 2004).

DEMOGRAPHIC FACTORS

In addition to changes across developmental stages, demographic factors shape the type, amount, and influence of parental involvement. The most notable are socioeconomic and ethnic/cultural factors. Motivations for parental involvement are based in parents’ perceived role in their children’s academic lives, a role which is culturally derived. Further, families’ experiences with and perceptions of their ethnic minority status vis-à-vis the school culture and population influence their engagement with their children’s schooling. Extant literature suggests that there are socioeconomic and ethnic differences in levels of involvement and its influence on achievement. For example, being college educated and from higher income levels is associated with higher levels of involvement in children’s schooling (Kohl, Lengua, McMahan, & Conduct Problems Prevention Research Group, 2000; Moles, 1993; Reynolds, Mavrogenes, Bezruczko, & Hagemann, 1996).

However, the research on ethnic differences is less conclusive. Some find that African Americans and Latinos are involved less than Euro Americans (Moles, 1993; Reynolds, Mavrogenes, Bezruczko, & Hagemann, 1996), others find no differences (Harris, Kagey, & Ross, 1987; Hill & Craft, 2003) and still others find that African Americans and Latinos have high expectations and involvement in their children’s education (Chavkin & Williams, 1989; Lopez, Sanchez, & Hamilton, 2000). In contrast, Asian American families have been found to have the lowest levels of involvement in their children’s education, especially when involvement is defined by interactions with the school (Kao, 1995; Sui-Chi & Willms, 1996). Variations across studies may be due to types of measurement and potential confounds between ethnicity and other demographic factors such as socioeconomic status and community resources. For example, the extent to which Latino families were the numerical minority within their communities and their children were numerical minorities among the school population influenced the amount and effectiveness of parental involvement in education (Rodriguez, 2002).

Beyond mean level differences, ethnic and socioeconomic differences have been documented in the goals for involvement and in the associations with academic outcomes. African American and Latino families often report that one of the reasons for being involved at school is to demonstrate to their children’s teachers that they are committed to their children’s education (Gutman & McLoyd, 2002). This is a goal that is often necessary because of biases teachers often hold about the academic potential of

African American and Latino children and the value their parents place on education (Ferguson, 1998; Hill, 2001; Lareau, 1987). This goal is unnecessary for Euro American and Asian American families, who often benefit from positive stereotypes held by teachers and other school personnel. Further, there is evidence that processes by which involvement influences vary by ethnicity and socioeconomic status. Hill and Craft (2003) found that parental involvement was associated with academic outcomes because it increased academic skills for African Americans. In contrast, for Euro Americans, it improved social and emotional competence in children (Hill & Craft, 2003). Similarly, parental involvement was differentially associated with achievement based on whether parents had college degrees (Hill et al., 2004).

Despite differences in the amount and types of involvement across demographic background, parental involvement and family school relations are positively associated with academic achievement and children's aspirations (Hill & Taylor, 2004). Two meta-analyses have been conducted on the extant literature that attest to its positive influence. Meta-analyses aggregate across empirical studies to ascertain a level of effect in a way that accounts for differences in sample size and quality of measurement. Looking at studies across developmental levels, the relation is positive and practically meaningful (Fan & Chen, 2001). The relation is strongest for parents' expectations and aspirations for their children. For studies focusing specifically on middle school age children, a developmental stage that is notable for its issues of adjustment, the relation is also positive (Hill & Tyson, 2007). The strongest positive influence was for involvement characterized as "academic socialization," defined as communicating the importance or value of education and linking schoolwork to students' interests or goals. Interestingly, for middle school students, parental assistance with homework was negatively associated with achievement (Hill & Tyson, 2007).

Given the positive influence parents have on their children's academic development, many programs and policies look toward involving parents as a way to mitigate gaps in achievement and help children reach their potential. Among the barriers to parental involvement, the most significant ones include conflicting schedules (time), feeling unwelcomed and unappreciated, and feeling unheard. Creating ways for parents to interact with teachers and school personnel as their schedule permits will improve communication. This may include the use of technology, including e-mail, e-bulletin boards, and voice mail (Bouffard, 2006). Further, schools and families may differ in their implicit and explicit expectations for parental involvement. Communications between families and schools that affirm and celebrate differences, acknowledge and build upon strengths, and make explicit

the goals and assumptions of involvement are essential in helping families feel welcomed and involved.

PARENTING STYLES

Parenting style refers to the normative patterns of behavior and tactics that parents use to socialize and control their children. Early work on parenting styles in the 1950s (e.g., Sears, Maccoby, & Levin, 1957) documented that adults who were nurturing and able to exert control were especially influential on children's development of self-regulated and disciplined behavior. Others (Lewin, Lippitt, & White, 1939) documented that adult leadership styles in classroom-like settings resulted in different levels of engagement on the part of children, with relatively warm and egalitarian styles resulting in greater task involvement, more self-regulated and autonomous behavior, and more competent performance than either highly controlling or permissive styles. From this work evolved a general approach to the study of parenting styles focused on socialization strategies reflecting demandingness and responsiveness. Demandingness, or control, refers to the degree to which parents attempt to integrate a child into the family social system by enforcing family rules and standards for behavior, setting expectations that are developmentally appropriate, and providing structure; responsiveness, or warmth, refers to parental attempts to support the development of their child's individuality and self-assertive tendencies by being attentive to the child's emotional well-being, special needs, and interests.

BAUMRIND'S TYPOLOGY OF PARENTING STYLES

Following this early work, Diana Baumrind (1971) conducted extensive observations of parents interacting with their children in their homes and concluded that four dimensions of parent-child interactions reflecting types of responsiveness and control could predict reliably children's social, emotional, and cognitive functioning. Parental control reflected consistent enforcement of rules, provision of structure to children's activities, and persistence in gaining child compliance; maturity demands reflected expectations to perform up to one's potential,

and demands for self-reliance and self-control; clarity of communication reflected the extent to which parents solicit children's opinions and feelings, and use reasoning to obtain compliance; and nurturance reflected parental expressions of warmth and approval as well as conscientious protection of children's physical and emotional well-being.

These dimensions were then used to develop a typology of qualitatively different parenting styles based on levels of responsiveness and control: authoritative, authoritarian, permissive indulgent, and permissive uninvolved (Baumrind, 1971; Maccoby & Martin, 1983). Authoritative parenting is responsive and demanding in that parents communicate high expectations, provide clear standards for behavior, monitor child behavior, and discipline based on reasoning and explanation rather than power assertion or withdrawal of love. Authoritarian parenting is similar to authoritative parenting in terms of being demanding; however, parents are described as less responsive in that they are more likely to use power assertive disciplinary techniques and rely on love withdrawal to gain child obedience. Permissive indulgent parents display relatively high levels of responsiveness but low levels of control. Specifically, this style is typified by low levels of control and maturity demands, but high levels of solicitation and demonstrations of warmth. In contrast, permissive uninvolved parenting is described as being relatively low on both warmth and control. At its extreme, this style is considered to be rejecting or neglectful of children.

CORRELATES OF PARENTING STYLES

There is widespread recognition that Baumrind's dimensions describe socialization processes central to the development of childhood and adolescent social and cognitive competence (Grusec & Goodnow, 1994; Maccoby & Martin, 1983). Baumrind's studies established that elementary-aged children of authoritative parents display adaptive levels of self-reliance and self-esteem, and socially responsible, independent, and achievement-oriented behavior; children with authoritarian parents display relatively less independent behavior and lower levels of self-reliance and self-esteem; and children with permissive parents display less positive behavior and self-reliance but high levels of self-esteem. Work by Steinberg and his colleagues (Steinberg, Lamborn, Darling, Mounts, & Dornbusch, 1994) supported the validity of the four-dimension typology in that adolescents with authoritative parents fared best with respect to a range of social, emotional, and academic competencies; students with authoritarian parents reported relatively lower levels of psychological well-being; those with indulgent parents were characterized as enjoying high levels of psychological and emotional well-being but lower levels of achievement

The four parenting styles and their effects	
<p>The authoritative parent Affectionate and engaged Sets limits and enforces consequences Uses reason, logic, and appropriate negotiation Empowers a child's decision making</p>	<p>His or her child is likely to be Happy, responsible, and kind Good at problem-solving Self-motivated and confident Cooperative An excellent student A leader</p>
<p>The authoritarian parent Emotionally aloof Bossy; likely to say, "Because I said so" Uses physical punishment or verbal insults Dismisses a child's feelings.</p>	<p>His or her child is likely to be Moody and anxious Well-behaved An average to good student A follower</p> <p>His or her child is likely to be</p>
<p>The permissive parent Affectionate Anxious to please, ends every sentence by asking, "OK?" Indulgent Can't say no and stick to it Easily manipulated</p>	<p>His or her child is likely to be Demanding and whiny Easily frustrated Lacking kindness and empathy A poor to average student A follower</p>
<p>The passive parent Emotionally removed or indifferent Uninvolved Abdicates discipline Inconsistent and unpredictable</p>	<p>His or her child is likely to be Clingy and needy Inappropriate and rude Likely to get into trouble A poor student A follower</p>

coupled with higher levels of misconduct; and students with uninvolved/neglectful parents were characterized as demonstrating the lowest levels of competence in all areas. Moreover, over the course of the high school years, the academic functioning of adolescents with neglectful parents declined and levels of delinquency and internalizing symptoms such as depression increased significantly, especially in comparison to that of students with authoritative parents.

Other researchers have documented similar advantages for children with authoritative parents such that they demonstrate competent social interaction skills, self-reliant and independent problem solving, emotional well-being and overall psychological adjustment, and few maladaptive internalizing and externalizing behaviors (Grusec & Goodnow, 1994; Pomerantz, Grolnick, & Price, 2005). These children enjoy academic success, demonstrate socially responsible and prosocial forms of classroom behavior, and competent relationships with their peers. They also report strong intrinsic interest in learning, positive beliefs about ability and control, and mastery goal orientations toward learning (see Wigfield, Eccles, Schiefele, Roeser, & Davis-Kean, 2006). It is important to note, however, that few of these findings reflect comparisons of parenting styles based on

Baumrind's typology, but rather on parenting described more generally along dimensions of control or warmth or in terms of authoritative versus non-authoritative parenting.

CLASS, ETHNICITY, AGE, AND GENDER

The benefits of authoritative parenting have been documented mostly in samples of middle-class families in industrialized Western societies. However, some evidence indicates that parenting in working class and low socioeconomic status families tends to be more authoritarian, with fathers using power assertive discipline more often than mothers. Children raised in more communal and extended family networks such as those found in Native American cultures, tend to be treated more permissively than European American children. Chinese mothers tend to demonstrate more controlling, authoritarian parenting practices than their European American counterparts (Fisher & Lerner, 2005). Research on age-related differences suggests that as children get older, outward displays of warmth and affection and direct disciplinary encounters by parents lessen, as verbal communication and discussion increase. Parents also tend to provide greater opportunities for autonomy and self-regulation as children enter adolescence and early adulthood (Maccoby, 2007).

Despite these group-level differences, the positive effects of responsiveness and developmentally appropriate levels of control are quite similar for all children. However, work on gender differences suggests that girls tend to be generally more susceptible to socialization practices than boys, whereas parental control tends to be more critical for boys' well-being than for girls' (Pomerantz et al., 2005; Weiss & Schwartz, 1996). Authoritative parenting also tends to predict social competence and adaptive psychological functioning for African American, Asian American, European American, and Hispanic American children; positive relations between authoritative parenting and academic outcomes have been found mostly for European American children.

CONCEPTUAL AND METHODOLOGICAL ISSUES

Although findings have been fairly robust and consistent with respect to the benefits of responsive and demanding parenting, several conceptual and methodological issues preclude strong conclusions about the effects of parenting styles on children. A central issue is that most researchers document parenting on the part of just one parent, most often the mother. Little is known about the frequency with which both parents display similar parenting styles or about the effects of discordant styles on children's development. Similarly, few studies document parenting styles

within the context of broader family systems. It also is not clear how consistent parenting styles are across contexts and age of the child. In this regard, the degree to which consistency moderates the effects of parenting styles on child outcomes is not known. However, inconsistent parenting has been related to aggressive and noncompliant behavior throughout childhood and adolescence (Wentzel, 1994).

Additional concerns surround the methods employed to document parenting styles (Maccoby, 2007). In studies of young children, observations of mother-child interactions during prescribed laboratory-based activities typically are used to identify specific parenting styles. Or mothers are asked to self-report on their parenting behaviors. In the case of observational studies, issues focus on how to capture behavior in real time and take into account the sequential and reciprocal nature of parent-child interactions. Decisions concerning whether to interpret interactions as a function of time, event, or context also are cause for debate. The use of mothers' reports has been met with concern given the psychological investment that mothers have in presenting themselves and their children in the best light. In studies of older children, self-report methodologies typically are used to ask children about their parents' behavior. In this case, researchers place importance on children's cognitive understanding of their parents' actions rather than on objective forms of behavior. However, the degree to which these reports are reliable and valid assessments of parents' behavior as opposed to characteristics of the child is not well understood.

Of final interest are the processes and mechanisms by which parenting styles might have their influence on child outcomes. To illustrate, reasons for why responsive parenting should be related to a child's academic performance have not been well articulated. Darling and Steinberg (1993) argued that parenting styles are part of a more complex system of parental inputs that include goals and expectations for their children (e.g., expectations for academic performance) and provisions of opportunities, resources, and instruction (e.g., academic enrichment programs, help with homework) targeted at achieving specific outcomes (e.g., mastery of academic subject matter). Additional research and theorizing that clarifies these possibilities is needed.

OVERVIEW

Experiences with peers constitute an important developmental context for children and adolescents (Rubin, Bukowski, & Parker, 2006). Children's experiences with peers occur on several different levels: general interactions with peers, friendships, and in groups. Social competence reflects a child's capacity to engage successfully with peers at different levels. This section will provide an introduction and overview of friendships, peer groups, and sociometric status, with attention to developmental changes that occur during childhood and adolescence.

FRIENDSHIPS

Friendship refers to a close, mutual and voluntary relationship. For many decades Harry Stack Sullivan's 1953 theorizing has provided a conceptual framework for the development and functions of friendships. Sullivan described friendships as providing the following functions: (a) offering consensual validation, (b) bolstering feelings of self-worth, (c) providing affection and a context for intimate disclosure, (d) promoting interpersonal sensitivity, and (e) setting the foundation for romantic and parental relationships. Sullivan believed these functions developed during childhood and that true friendships were formed around the age of 9 or 10.

More recently, Thomas Berndt's 2004 study described four types of support that friends provide for each other: informational support, instrumental support, companionship support, and esteem support.

Informational support refers to guidance and advice in personal problems with parents, romantic relationships, teachers or other friends. Instrumental support refers to help on any type of task, such as homework or chores. Companionship support refers to reliance on friends to do things with, such as someone to eat lunch with or go to a dance or sporting event. Esteem support refers to the encouragement friends provide both when life is going well (e.g., congratulating each other) and when life does not go as one hoped (e.g., consoling in the face of failure).

In general as individuals move from childhood to adolescence, they spend more time with their peers and less time with their family. There is less adult supervision when they are with their friends and increasingly they have more friends of the opposite sex (Brown, 2005). In addition, individuals' conceptions of friendships change as they progress through childhood and adolescence.

Friendship conceptions are measured by asking children questions such as "What is a best friend?" For very young children, friendship conceptions are driven by the social activities in which they are engaged. As they age, children become more sophisticated in their notions of friendship. Generally, friendship conceptions progress from

concrete to more abstract with age. During childhood and into adolescence, friendships become more stable as well as increasingly characterized as reciprocal and intimate. The development of children's friendship conceptions has been studied by Robert Selman and James Youniss. Selman (1980) emphasized the evolving perspective-taking abilities that underlie the changes in friendship conceptions. Youniss (1980) emphasized the importance of reciprocity in the development of children's friendship conceptions.

PEER GROUPS

The term *peer group* refers to an individual's small, relatively intimate group of peers who interact on a regular basis (often referred to as a clique). Peer groups consist of individuals who share friendship, hang around and talk to each other as well as do activities together. As children develop into adolescents, they spend an increasing amount of time with their peers compared to their parents or other adults (Csikszentmihalyi & Larson, 1974). The nature of peer groups also changes during adolescence. Typically, in early adolescence peer groups are single-sex but by middle adolescence mixed-sex peer groups are more prevalent. During late adolescence peer groups start to disintegrate as individuals spend more time as part of a romantic couple (see Brown, 2005 for a review).

Research has documented that peer groups exhibit similarity in many characteristics and attributes. The tendency of individuals to affiliate with others who share similar attributes is a social dynamic called homophily. Homophily of peer group beliefs and behaviors has been found across a wide range of outcomes. For example, adolescent peer groups have been found to be more homogeneous than the student body as a whole on reported frequency of smoking, drinking, drug use, and dating (see Rubin and colleagues, 2006, for a review). Homophily of peer groups has also been found among peers along academic characteristics such as GPA, college aspirations, time on homework, and general engagement in schoolwork. Two processes contribute to homophily: socialization and selection. Socialization refers to the tendency for friends to influence similar attributes in each other over time. Selection refers to the tendency for individuals to choose friends with similar attributes.

Socialization (also referred to as peer influence or peer pressure) most likely manifests itself in both direct and indirect ways. For example, social reinforcement may play a role. Beliefs and behaviors that are discouraged or received negatively by the peer group are less likely to be displayed again by an individual. Conversely, beliefs and behaviors that are encouraged or positively received by the peer group are more likely to surface again in the presence of one's peers. However, peer influence is also likely to occur in less direct ways. For example, modeling processes

are likely to be involved in peer influence. Observing a friend's commitment to schoolwork or voicing a belief about the meaning of school could introduce an individual to new behaviors and viewpoints. Depending on the consequences, observation of a model can strengthen or weaken the likelihood that the observer will engage in such behavior or adopt such beliefs in the future (Bandura, 1986). Finally, peer influence is also likely to occur through subtle means such as gossip, teasing, and humor. Gossiping about others, for example, is a means of clearly communicating unacceptable behavior without direct confrontation (Eder & Sanford, 1986). Thus, students share experiences and exchange information (in subtle and not so subtle ways) and out of these interactions among peer group members a context emerges regarding norms and values. This peer group context is likely to influence many outcomes, including adolescents' motivation and engagement in school (Kindermann, 1993; Ryan, 2001).

SOCIOMETRIC STATUS

Sociometric status is distinct from friendship or peer group membership and concerns overall peer acceptance (i.e. the experience of being liked or disliked by peers). Research in the field of developmental psychology has a long tradition of using sociometric assessment techniques to assess peer acceptance. Sociometric assessment techniques are used to identify who is liked or disliked. For example, children might be asked to nominate three to five peers who they "really like," or "like to play with," or "do not like" or "do not like to play with." The peer nominations are then used to classify students into different social status categories. Coie, Dodge and Coppotelli (1982) devised five different categories that are widely used by researchers: (a) popular children who receive many positive and few negative nominations, (b) average children who receive an average number of positive and negative nominations, (c) neglected children who receive few positive and negative nominations, (d) rejected children who receive few positive and many negative nominations, and (e) controversial children who receive many positive and many negative nominations.

Much research has examined the characteristics of children classified as popular, average, neglected, rejected, and controversial (see Rubin and colleagues, 2006, for a review). While there are some general trends there is variability within each group. Popular children tend to be sensitive, cooperative, easily join others in social activities, and often take on a leadership role. Neglected children are low in peer interaction of any kind and generally do not call attention to themselves. Rejected children are the most at risk. Researchers have distinguished between rejected children who are aggressive, those who are withdrawn, and those who are aggressive-withdrawn. In the short-term, aggressive, rejected

children have conduct problems and antisocial behavior in school. Withdrawn children report feeling lonely, are more depressed, and have low self-image. Aggressive-withdrawn children are the most at risk for all of these problems. In the long-term, rejected children are more at risk for mental health problems, delinquency, low achievement, and dropping out of school. Controversial children have characteristics that are represented in many of the groups.

It is important to note that there are other measures of peer acceptance or social status besides sociometric techniques. For example, researchers have measured popularity in different ways. The sociometric tradition asks children to list who they like and who they dislike in a classroom. Another way is to ask children directly to identify who is popular or ask them to rate their own popularity (referred to as perceived popularity). Different measures highlight different aspects of peer acceptance and social status. Sociometric techniques highlight the likeability of students whereas the measures of perceived popularity highlight social centrality and visibility. Researchers interested in aggression have noted that these different measures can lead to different conclusions about how the peer system operates. For example, sociometric popular children tend not to be aggressive but there is a positive correlation between perceived popularity ratings and aggression (Cillessen & Rose, 2005).

FRIENDSHIPS

Relationships with peers are of central importance to children throughout childhood and adolescence. Children who enjoy positive relationships with peers experience levels of emotional well-being, beliefs about the self, and values for prosocial forms of behavior and social interaction that are stronger and more adaptive than do children without positive peer relationships. They also tend to be engaged in and even excel at academic tasks more than those who have peer relationship problems (Rubin, Bukowski, & Parker, 2006; Wentzel, 2005).

Researchers who study peer relationships typically focus on one of two peer contexts: children's dyadic friendships and their larger peer groups and crowds (Rubin et al., 2006). The major distinction between friendships and involvement with the broader peer group is that friendships reflect relatively private, egalitarian relationships often formed on the basis of idiosyncratic criteria. In contrast, peer groups are defined by publicly acknowledged and therefore easily identified and predictable characteristics that are valued by the group. Larger peer groups often are comprised of students who have formed close dyadic friendships with each other. However, friendships are enduring aspects of children's peer relationships at all ages, whereas peer groups and crowds emerge primarily in the middle school years, peak at the beginning of high school, and then diminish in prevalence as well as influence by the end of high school (Brown, 1989).

FUNCTIONS, QUALITIES, AND CORRELATES OF FRIENDSHIPS

Friendships have been described most often with respect to their qualities and functions (Newcomb & Bagwell, 1996; Parker & Asher, 1993). They provide a source of companionship and entertainment; help in solving problems, personal validation, and emotional support; and especially during adolescence, offer a foundation for identity development. Research on friendship formation based on interviews and observations of children at school suggests that positive friendships are most likely to be developed and maintained over time when children display personal attributes such as the ability to communicate responsively,

exchange information, and establish common ground, and when they can self-disclose, extend and elaborate the activities of others, resolve conflict, and provide emotional support (Gottman, 1983). These characteristics tend to differ as a function of age. Young children describe their friendships in terms of specific overt characteristics such as spending time together or having common interests; older children are more likely to include psychological characteristics such as intimacy, self-disclosure, loyalty, and commitment in describing their friends. Friendships also become more stable as children develop (Rubin et al., 2006).

Researchers also have documented differences in the quality and type of interactions that children have with friends and with non-friends (Newcomb & Bagwell, 1995). In this research, friendships are determined most often on the basis of students' nominations of their best friends at school, which are then matched to determine reciprocity, or best friendships. Characteristics of reciprocated friends are then compared to those of children who do not mutually nominate each other. These studies indicate that when children interact with friends they display significantly greater amounts of social contact such as talking, cooperation, and positive affect, they demonstrate more concern with resolving interpersonal conflicts and are less likely to instigate conflict, and they are more productive and use resources more efficiently when engaged in cognitive-related tasks together than they do with non-friends. Relationships of friends also are characterized as more balanced with respect to mutuality and reciprocity, as having stronger affective bonds, and stronger levels of mutual trust and commitment than those of non-friends. Compared to non-friends, friends also have in common more interests, values, activities, levels of prosocial as well as aggressive behavior, and personality characteristics (Wentzel, 2005). Research on school-based motivation indicates that friends are similar in the degree to which they value academic achievement, set goals for educational accomplishments, and pursue goals to behave in prosocial ways (e.g., Wentzel, Barry, & Caldwell, 2004).

Moreover, researchers have studied the relations of having friends to children's development (Wentzel, 2005). For the most part, simply having one friend as opposed to no friends appears to be related to a range of positive outcomes for students of all ages (e.g., Parker & Asher, 1983). When compared to their peers without friends, children with reciprocated friendships tend to be more sociable, cooperative, self-confident, independent, emotionally supportive, altruistic and prosocial, and less aggressive. Elementary school and middle school students with friends also tend to earn better grades and score higher on standardized tests, and to be more involved and engaged in school-related activities than those who do not have reciprocated friendships. Children without friends are

often more lonely, emotionally distressed, and depressed than children with friends.

The supportive function of friendships is demonstrated in research showing that students who make school transitions with friends show overall better adjustment during and after transition periods (e.g., when they enter formal schooling, middle school, and high school) than those who do so without friends (e.g., Ladd & Price, 1987; Wentzel et al., 2004). Students who have established friendships with classmates also are more likely to enjoy a relatively safe school environment and are less likely to be the targets of peer-directed violence and harassment than their counterparts without friends (e.g., Schwartz et al., 2000). This safety net that friends appear to provide each other is critical in that peer-directed violence and harassment is a fairly pervasive problem in U.S. schools and can have an enormous negative impact on students' social and emotional functioning.

Although the importance of friendships in early development should not be understated, it is well documented that friendships play their most pivotal role in development during the adolescent years (Youniss & Smollar, 1989). During this time friendships are believed to provide a unique avenue for identity development; furthermore, during this time the strongest relationship between the experience of positive friendships and the numerous associated positive outcomes are found. In this stage of development, children exhibit increased psychological investment in their peers and dependence on friends for support.

HOW FRIENDSHIPS INFLUENCE DEVELOPMENT

It is likely that significant associations between having friends and other positive competencies partly reflect the fact that students who demonstrate competence in one domain of functioning (i.e., making friends) often do so in other domains. Of interest, however, is the extent to which these significant relations also reflect a process whereby change in competencies occurs as a result of friend influence (Hartup, 1966). For instance, simply having a close friend might have developmental significance for healthy adjustment over time. Individuals also might adopt or develop specific behavioral styles or interests because they are considered to be desirable characteristics of their close friends.

In general, however, there are many unanswered questions concerning how friendships exert their influence on development. Some of these questions concern the timing, stability, and quality of friendships. For example, one unknown concerns whether there are critical periods during which friendships have more powerful effects on certain developmental outcomes. Can a child be friendless in middle school, establish a friendship in

high school, and still experience the protective effects friendships are proposed to offer? Some researchers have suggested that the cumulative experience of friendships is important to development rather than any one particular friendship in one place or time (Hartup & Stevens, 1997). Another question concerns the directionality of influence: Do children have high quality friendships because they already possess the necessary skills to make friends, or do they develop positive social skills within the context of their friendships? As of 2007, empirical evidence that addresses these questions is limited. Longitudinal studies that assess the characteristics of both friends at multiple points in time are necessary to determine the nature and magnitude of change in each individual over time. There is also an evident gap in the literature addressing friendships outside the classroom or school. The role of neighborhood friends or friendships within a family network in development and learning are in the early 2000s studied infrequently.

In spite of these limitations, presumably some form of influence from friends is likely to take place. If such influence does occur, however, an important question is why. Explanations of influence often focus on the likelihood that positive emotional attachments to friends promote healthy psychological functioning; feelings of relatedness and belonging that results from having friends are believed to contribute directly to positive feelings of self-worth and self-esteem. In turn, these levels of emotional well-being are believed to contribute to adaptive functioning in social as well as academic domains. Substantial evidence based on children at all ages supports this perspective (Wentzel, 2005).

Some scholars posit an observational learning explanation of influence in which a friend models behavior that is subsequently adopted by a child who observes the behavior (Wentzel et al., 2004). Empirical findings provide support for this position in that children have the opportunity to observe their friends' behavior with greater frequency than non-friends' behavior. In addition, behavior that is learned by observing others is likely to be enacted to the extent that an individual is motivated to do so (Bandura, 1986). Therefore, a child's behavior might become more similar to a friend's behavior because of a change in underlying motivational processes such as goals and self-concept. Research on motivation documents that peers serve as powerful models that influence the development of academic self-efficacy, especially when children observe similar peers who demonstrate successful ways to cope with failure (Schunk, 1987). These modeling effects are especially likely to occur when students are friends, although students who have higher achieving friends tend to have lower levels of self-efficacy than those with lower-achieving friends (Altermatt & Pomerantz, 2005).

Finally, theorists have proposed that positive interactions with peers contribute directly to intellectual development and functioning. For example, Piaget (1965) argued that mutual discussion, perspective taking, and conflict resolution with peers can motivate the accommodation of new and more sophisticated approaches to intellectual problem solving. Research has supported his position in that active discussion, problem solving, and elaborative feedback among peers are associated with advances in a range of cognitive competencies, including problem-solving skills, conceptual understanding, and metacognitive reasoning in samples ranging from preschool to high school (Gauvain & Perez, 2007). Of relevance for understanding the influence of friends on cognitive development is research indicating that interactions with friends rather than acquaintances tend to yield more predictable cognitive advances, presumably because friends have well-established interaction patterns and are sensitive to each other's interests and needs. In this regard, working with friends rather than acquaintances tends to result in positive outcomes for girls more than for boys (Newcomb & Bagwell, 1995).

SCHOOL BASED INFLUENCES ON STUDENTS' FRIENDSHIPS

Of final interest for educators and practitioners is evidence that teachers can have a significant influence on the nature and establishment of students' friendships (e.g., Donohue, Perry, & Weinstein, 2003; Stormshack, Bierman, Bruschi, Dodge, & Coie, 1999). For example, teachers' perceptions of students' academic aptitude, intelligence, and tendency to misbehave are related to students' choice of friends. Elementary-aged students appear to be aware of the categorizations their teachers make about their classmates and will reject or accept them based on characteristics such as their troublesomeness or smartness accordingly. Students perceived to be smart are consistently viewed in a more positive light, whereas those ranked as troublemakers tend to be socially rejected. This phenomenon is especially true for girls.

The instructional approach a teacher adopts, and the resulting classroom organization, also has an impact on students' opportunities to make friends (Epstein, 1983). Adolescents with teachers who employ learner-centered practices (e.g. involve students in decision making, emphasize the importance of building positive social relationships) as opposed to teacher-centered practices (e.g. focus on rote learning, evaluation) report having more close friends and obtain a greater number of friendship nominations in general. Middle and high school students in classrooms where frequent interactions with classmates are condoned, that is, where students are encouraged to talk to each other about class assignments, to work in small

groups, and to move about while working on activities, also are less likely to be socially isolated or rejected by their classmates, enjoy greater numbers of friends, and experience more diversity and stability in their friendships. The degree to which middle schools and high schools are ethnically diverse, as opposed to having clear majority and minority groupings, also can influence the nature and stability of students' friendships (Urberg, Degirmencioglu, Tolson, & Hallidayscher, 1995).

PEER GROUPS

Peers constitute one of the most important contexts for child development and socialization. Beyond their function as companions in leisure activities they serve as sources of instrumental and emotional support, help a child formulate values and beliefs, and oversee a child's adherence to behavioral norms of the peer culture and broader society. Much of a child's interactions with peers takes place in peer groups, making it important for others to understand how peer groups are organized, how they operate, and how these factors change from early childhood through adolescence. North American youth are more likely to encounter peers in schools than any other single social context, making schools a major locus of peer group interactions (Brown, 2004). This entry gives an overview of child and adolescent peer groups, paying particular attention to the role that schools play in these groups.

EARLY EXPERIENCES WITH PEER GROUPS

During the toddler and preschool era, young people's interactions with peers tend to be organized and closely supervised by adults, giving young people little opportunity

to choose their peer groups (Ladd & Golter, 1988). Moreover, peer groups are often ephemeral, emerging from a specific, structured activity (such as a play group organized by parents) and dissolving when the activity ends. In this context children are expected to master the tasks of group entry and group interaction. According to Putallaz and Gottman (1981), those who can adjust to the group's ongoing interests, rather than disrupting group functioning by trying to impose their own agenda, are more successful entering groups and better prepared to participate in the peer groups that will emerge in school settings.

Once young people enter more stable peer settings, such as a school classroom, they can exercise more choice in their peer associates and their groups become more stable. Nevertheless, Kindermann (1993) notes that in these early school years peer groups feature high turnover in membership from one month to the next. Most groups are formed among youth who have ample opportunity to interact (e.g., live in the same neighborhood or are in the same classroom at school) and share a strong interest in the activity that inspires the group's formation. Once past the preschool years, both girls and boys show a preference for forming groups of same-sex peers, an inclination that Ennett and Bauman (1996) found will continue until middle adolescence.

PEER GROUPS IN MIDDLE CHILDHOOD

As young people move past early childhood and the primary grades of elementary school, peer group interactions typically expand. Young people try to join structured after-school activities or organize informal after-school interactions that include the friends they have in school classrooms. Despite this behavior, peer group membership remains highly volatile. Cairns and his colleagues (1995) found that, over the course of a school year, the core of a group may remain intact while more peripheral members float among groups, but it is unlikely that a group will experience no changes in membership over this time period. One reason for this flux is the rather loose structure of peer groups that characterizes middle childhood. Shrum and Cheek (1987) reported that in any given classroom several sets of students will band together into cliques, but collectively they may constitute little more than half of the students in a class. Other students will seem to have attachments to two or more cliques and often serve as a conduit of information between groups (someone who can facilitate a child's transfer between cliques). Still others may bond together in a close friendship and confine interactions to the dyad, while a small cadre of students can be regarded as isolates without close relationships with any classmates (although they may have strong ties to a friend or clique outside the

classroom). Researchers disagree about the percentage of youth who belong to cliques, largely because of differences in the ways that these groups are defined or identified. It seems, however, as if membership in a tight-knit peer group actually diminishes across time, contradicting the stereotype of early adolescents as highly clique oriented (Shrum & Cheek, 1987).

More consensus exists on the average size of peer groups. Cliques usually contain between five and eight members. Ladd (1985) found that boys' groups tend to be larger than those of girls, possibly in order to facilitate boys' more active pursuits (e.g., sports) on the playground. Also, according to Ladd (1985), children who are well liked by classmates belong to larger cliques than peers who are generally disliked.

Cliques bring together children who share common interests and social backgrounds (socioeconomic status or ethnicity). One might also expect clique members to share similar personality dispositions or temperaments, but this is not always so. Whereas many people believe that relatively aggressive youth coalesce into peer groups that are distinct from those of nonaggressive youth, Farmer and colleagues (2002) discovered that aggressive children actually are widely dispersed among cliques. However, cliques do vary in the average level of aggressiveness of group members, and this group average correlates significantly with the level of academic and social adjustment of group members (Farmer et al., 2002). If a student who is relatively aggressive and disliked by peers belongs to a relatively aggressive peer group, the child will have difficulty mastering the social skills necessary to move into a more prosocial peer group and gain a more favorable reputation among classmates.

As is true among older youth or adults, children are inclined to favor members of their peer group over outsiders. They recognize and accentuate group differences in attitudes and behaviors. Toward the end of childhood, however, young people are likely to differentiate highly regarded, core group members from more peripheral and less popular members, especially if these peripheral members do not adhere closely to group norms. A child may even favor peers who are members of so-called out-groups over fellow clique-mates who tend to deviate from the clique's norms, especially if the peers in the out-group are not highly committed to their group's norms (Abrams, Rutland, & Cameron, 2003). Bigler, Brown, and Markell (2001) demonstrated that school adults can exacerbate rivalries and hostilities among peer groups by calling attention to the groups (e.g., allowing children to form their own work groups or teams at recess), even if the adults show no favoritism of one group over another.

EXPANSION OF PEER GROUPS IN ADOLESCENCE

The peer group system grows more complex in early adolescence, especially if young people move from neighborhood-based elementary schools to larger secondary schools that are no longer based on self-contained classrooms. The most significant change is the emergence of a second layer of peer groups, often referred to as crowds. In contrast to cliques, which identify students who routinely interact with each other, crowds differentiate individuals who share a similar reputation or image among peers, whether or not the crowd members routinely interact with one another (Brown, 2004).

Crowds are organized around the most salient features of the peer social system. They also tend to address developmental mandates of adolescence as a life stage (Brown, Mory, & Kinney, 1994). In the dominant mainstream of American culture, young people of this age are expected to become more autonomous from adults, cultivate a sense of identity, and master the skills necessary to participate in heterosocial interactions and relationships that form the normative social patterns of adulthood. Accordingly, peer crowds reflect different prototypic identities or lifestyles, based on individual abilities and interests: jocks, brains, delinquents, partyers, goths, skaters, and so on. Crowds also tend to be arranged in a social hierarchy, according to their status among peers (Brown et al., 1994). Sometimes group status forms the basis for a crowd's name: populars, nerds, rejects. Important cultural elements endemic to a particular school or community may also be reflected in the crowd system, such as when groups emerge that are based on ethnic background, religious orientation, or family economic background. Thus, the crowd with which an adolescent is associated by peers is an indicator of the child's status, public identity, and values or behavior patterns that are most noticeable to peers.

The importance of belonging to a crowd grows through early adolescence, peaks in middle adolescence (about the beginning of high school), then fades (Brown, Eicher, & Petrie, 1986). Nevertheless, Schwendinger and Schwendinger (1989) reported that even in middle adolescence, not all young people are associated definitively with one particular crowd. Some display a "split image," in which peers associate them with two different crowds, whereas others are not well enough known by peers to place in any crowd. It appears to be more difficult for adolescents to change crowd affiliations than it is to change clique membership.

In addition to their role in identity development, crowds help to regulate social interactions by indicating which peers are acceptable candidates for friendship or dating relationships (Brown et al., 1994). Crowds at either end of the status hierarchy in Eckert's 1989 study

of high school youth displayed rivalries or animosities that precluded close relationships between members. These may be manifest in physical confrontations, such as between rival gangs, but they are more likely to be expressed in verbal exchanges or criticisms of the rival group. Research by Cillessen and Mayeux (2004) revealed that members of high status groups are rated by peers as more verbally aggressive than low status crowd members. Their aggressive behaviors often serve to affirm and reinforce their superior status in the peer system. But there is a price to pay for such aggression, in that members of high status crowds are not necessarily well liked by peers.

Although there are strong antipathies or rivalries among certain crowds in a school, there can be close affinities among other combinations of crowds. This fact may explain why, at least in high school, Urberg, Degirmencioglu, Tolson, and Halliday-Scher (1995) found that friendship groups often contain members of multiple crowds. The inclination to form cliques from within a given crowd appears to be stronger among certain crowds than others, and during early adolescence rather than later years (Kinney, 1993). However, patterns of exclusiveness in clique formation can be exacerbated in schools or communities that emphasize distinctions among students by virtue of residence, ethnicity, religion, or other demographic markers.

Ethnographers who have studied clique dynamics have focused on early adolescent groups of high-status girls. They have observed a complex structure that involves multiple roles and a hierarchy of authority, often enforced through a pattern of relational aggression that makes the groups appear to undermine members' psychological well-being (Adler & Adler, 1998). It is unlikely that the same structure and group dynamics typify adolescent cliques, especially after the middle school years. Finders (1997), for example, found that within-group relations were much less intense and more supportive in a lower status girls' clique than the high-status counterpart in the middle school that she studied.

A major function of adolescent cliques is to socialize youth into heterosexual roles and relationships (Connolly, Furman, & Konarski, 2000; Dunphy, 1963). Accordingly, although same-sex groups still dominate the adolescent social landscape, mixed-sex cliques become increasingly common. Youth who are involved in mixed sex groups begin dating and romantic relationships earlier and with more confidence than young people who remain in single-sex cliques (Connolly et al., 2000).

Peer groups are instrumental in promoting prosocial behavior, such as academic achievement, as well as anti-social activities, depending upon the norms of the group. In Ellis and Zarbatany's 2007 study of Canadian youth, group influences toward deviant behavior were

significant only among low-status cliques, whereas group influences toward prosocial behavior were strongest in cliques of high-status students. Cliques do not have equal influence on all members. Tarrant, MacKenzie, and Hewitt (2006) found that those who identify strongly with their clique are more subject to its influence than members with more casual ties to the group. Cliques have indirect as well as direct effects on members' behavior and well-being. Lansford and colleagues (2003) reported that a strong and supportive friendship group can moderate the negative impact of poor parenting on young people.

As is the case for childhood cliques, schools can affect the dynamics of adolescent peer groups. Sponsoring ethnically based clubs or organizations helps to legitimize ethnically oriented crowds. Favoring one group of students over another (e.g., spotlighting athletes or giving them special consideration) can boost the cliques or crowds to which that group belongs. Separating students by academic ability or English language fluency creates divisions in the student body that affect the formation of friendship groups.

COALESCENCE OF CROWDS IN LATE ADOLESCENCE

By the final years of high school, most students have begun to solidify their sense of identity, located enduring friendships, and grown more comfortable with heterosocial activities. Having thus facilitated adolescent development, peer crowds diminish in importance and influence. In fact, the boundaries between crowds often dissipate, making it difficult to discern a crowd's members and making friendship groups that cut across several crowds more common (Brown et al., 1994). Young people's attention turns away from crowds, back toward their circle of friends. Peer groups function more as support systems than as powerful entities that direct student behavior, which helps to prepare students for the type of peer group experiences they are likely to encounter in adulthood.

PEER PRESSURE

Peer pressure is the influence that a group has on an individual. Although in common parlance peer pressure is frequently used to describe a negative influence, peer pressure can be both positive and negative. Young people are more susceptible to peer pressure at certain stages of development, but everyone is influenced by peers to some degree, even adults.

TYPES OF PEER PRESSURE

Peer pressure has been of interest to researchers for decades. In a series of experiments performed in 1955 and 1956, researcher Solomon Asch demonstrated the power of peer pressure to make otherwise intelligent individuals go against the evidence of their own eyes. He showed participants a straight line on a card and asked them to pick out which straight line on another card matched it. The straight lines on the second card were of quite different lengths, and when subjects performed the task alone they chose the correct line more than 99% of the time. However, when confederates of Asch became involved, the situation changed drastically. When every confederate chose the same, incorrect, line, the participant would choose the same, incorrect, line more than 36% of the time (Asch 1955). In general, the more confederates participating and choosing the incorrect line, the stronger this effect was found to be. This clearly demonstrated that, among the college student participants at least, the opinion of the group could exert such a strong influence that it could cause participants to choose against their better judgment. Interestingly, when even one confederate chose the correct line participants were more much more likely to choose the correct line (Asch 1956). This suggests that peer pressure is reduced when the group is not unanimous.

Asch's study was alarming because it showed that the influence of peers on judgment is so strong that it could make even intelligent college students choose the opinion of a group over the evidence of their own eyes. Since his groundbreaking experiments thousands of studies have

been done demonstrating the presence of peer pressure on children and adolescents in dozens of different situations and at nearly every age. Much of this research has focused on negative peer pressure, the peer pressure most likely to be of concern to parents and educators.

Peer pressure has the capacity to be an extremely negative influence on a child or adolescent. Many studies have documented that children whose friends engage in negative or antisocial activities, such as smoking or using drugs, are much more likely to engage in such behaviors themselves. Salvy and colleagues' 2007 study even found that overweight girls who ate with a friend who was also overweight consumed more calories on average than overweight girls who ate with friends who were of normal weight. This kind of influence on day-to-day habits, outside even the realm of traditional antisocial activity, demonstrates how prevalent peer influence can be. Ad campaigns such as the "just say no" campaign of the 1980s and early 1990s and the "above the influence" campaign, begun in the mid 2000s, are aimed at encouraging children and adolescents to recognize the influence of peer pressure and to overcome its pressure to engage in antisocial activities.

Although peer pressure is most frequently used in conversation with a negative connotation, not all peer pressure is negative. Peer pressure is a necessary and important part of development. It helps to socialize children, provide a sense of identity, and can encourage positive behaviors. Peer pressure can encourage children and adolescents to strive for excellence in areas such as sports, theater, and science. Peer pressure might make children feel pressured to take an honors class with all of their friends, which would not necessarily be right for every child but would by no means be antisocial. Peer pressure is an important fact of life at all ages; it is even a significant motivator for adults. A 2006 report to the House Science and Technology subcommittee reported peer pressure more effective at making American adults conserve energy than concern for the environment, the desire to save money, or even social responsibility. Given that peer pressure exists at all ages, it may be more effective to help children and adolescents identify negative peer pressure than to try to eliminate peer pressure.

SUSCEPTIBILITY TO PEER PRESSURE

Susceptibility to peer pressure varies with age and specific personal traits. In general, the role of peer pressure increases with age into adolescence. When children are very young, parents and other caregivers tend to choose play groups and babysitting situations. Parents limit the amount of time they allow children they believe to be bad influences to have contact with their children. Very young children also tend to spend less time in the company of

other children and more time with parents or other adult figures. Therefore, the presence of peer pressure is somewhat limited. As children enter school full time and begin to spend more of the day playing with peers outside the direct supervision of adults the potential for peer pressure increases.

Research is somewhat divergent about what age group is most susceptible to peer pressure. Some research indicates that the influence of peers steadily increases through middle school and peaks during the later years of high school. Recent research has suggested that this may not be the case. A 2007 study by Steinberg and Monahan found that resistance to the influence of peer pressure actually increases fairly linearly between ages 14 and 18, and does not increase significantly after that. They found that among the participants studied, ranging in age from 10 to 30, resistance to peer influence did not increase significantly from ages 10 to 14 or after age 18 (Steinberg, 2007).

In addition to changing with age, susceptibility to peer pressure also varies by individual. Children who have low self-confidence and a low sense of agency are more likely to be influenced by their peers. Children who are somewhat ostracized from the general group of peers may gravitate towards children who have also been ostracized, who may be more likely to engage in antisocial behavior. Children who are pushed out of the group may feel more pressure to conform in an attempt to be accepted by a group, even if the group is not engaging in prosocial activities.

FRIENDS VERSUS PEERS

Peer influence can come from many areas. It is not often found in the guise of one adolescent telling another adolescent directly, "Hey, everybody's doing it." It is usually more subtle but in many ways more insidious than that. Peer pressure most often comes from a peer group larger than the set of friends that the child or adolescent regularly interacts with. In this way peer pressure can be exerted indirectly, such as when everyone in school wears a certain type of sneakers or carries a certain brand of backpack. Although the influence is extremely dispersed, and it is not likely anyone will directly tell the children they need to buy those shoes or that backpack, the influence is none the less extremely strong.

Friendship group refers to the group of friends with which children or adolescents spend most of their time; the group to which they most closely relates. Friendship choice is often influenced by habits and interests the child already has. For example, an adolescent who smokes is more likely to be friends with a group of adolescents who also smoke than an adolescent who does not. Although already occurring traits can heavily influ-

ence friendship group choice, once the group has formed the members exert increased pressure on one another to conform.

Friendship groups are more likely than peer groups to exert direct, spoken pressure on a child or adolescent. The pressure to conform to the friendship group is also greater because fear of losing the primary friendship group can be severe. The friendship group can also help the child or adolescent resist pressure by the larger peer group to engage in antisocial activities. As was shown in the Asch experiment, even one other person standing against the group can provide enough incentive for individuals to go with their beliefs instead of with the group.

SOCIOMETRIC STATUS

Sociometry is defined as the quantitative measurement of social relationships. Jacob Moreno (1889-1974) is considered the founder of sociometric analysis, with his 1934 book *Who Shall Survive?* Sociometry, as Moreno and others since have envisioned it, has two major objectives. The first is to describe the structure of the peer group as a whole, for example, by creating sociograms or visual diagrams of peer group structure. The second objective is to assess the status of individuals within the group. Sociologists have generally been more interested in group structure, while social and developmental psychologists have tended to focus more on the sociometric status of individuals, although there is considerable overlap between the sociological and psychological research on

this topic. Bukowski and Cillessen provide an excellent review of the history of sociometry that explains its development during the twentieth century.

A vast number of empirical studies have investigated sociometric status among schoolchildren in the classroom setting. In the U.S. educational system, children spend an enormous amount of time with same-age peers in the classroom, so it is critically important to understand how each child fits within that group and to understand what are the consequences, both short-term and long-term, of having a particular status within the group. Furthermore, particularly in younger grades, the classroom setting provides researchers with a readily available, relatively self-contained peer group, which enables them to conduct sophisticated quantitative analyses of peer status and obtain very rich information about how the peer group functions and its effects on individual children.

MEASURING SOCIOMETRIC STATUS

The most common method of measuring sociometric status is to collect confidential nominations from the members of a peer group regarding who each person likes and who each person dislikes within the group. Occasionally, teachers, parents, or trained behavioral observers provide the data, but peer nominations are usually considered the best form of measurement. Peers understand the group from the inside, rather than viewing it from the outside, as others do. Also, the measurements are more direct with peers (“Who do you like?”) than with teachers or observers (“Who is well-liked by peers?”). Furthermore, while there will be some degree of bias no matter what the source of information is (parents, teachers, observers, or peers), one can obtain more reliable information by surveying a large group of peers than one would get from a single individual such as a teacher or an observer. Often researchers use multiple sources for collecting the data, and they can learn a great deal about peer status by examining the similarities and differences among these various sources of information.

Sociometric status is usually measured by counting the number of liked votes and the number of disliked votes that each person receives from peers, a method that was introduced into developmental psychology by Coie, Dodge, and Coppotelli in the early 1980s. There is some controversy from an ethical perspective about whether to include the negative (disliked) nominations when collecting data or simply collect the positive (liked) nominations only. Some teachers, parents, and/or school administrators believe that asking about disliking will lead some children to be ostracized when they would not have been so otherwise. However, others argue that these measures are simply assessing relationships and attitudes that already exist. More importantly, the prob-

lem with not using negative nominations is that there is a substantial difference between failing to name someone as liked and actually naming the person as disliked. Only by using both types of nominations can researchers categorize children into the five different categories of sociometric status (described below) upon which most of the research in this field is based.

The five-category model proposed by Coie and colleagues involves counting the number of votes received by each student for liking and disliking and standardizing those votes within the classroom. In some cases, children are allowed to make an unlimited number of nominations, while in other cases, they are restricted to a specific number of nominations, (three, for example). Also, sometimes the nominations are only for same-sex peers (especially in younger grades) and sometimes they are across both genders. The first two categories that can be derived from these nominations differ along a dimension of social preference. The first category is sociometrically popular, which includes children who receive a large number of liked nominations and very few if any disliked nominations. The second category, sociometrically rejected, includes children who receive a large number of disliked nominations and very few if any liked nominations. The popular children are (obviously) more preferred than the rejected children. The next two categories differ along a second dimension, called social impact. These categories are sociometrically controversial, which includes children who receive many liked nominations and many disliked nominations, and sociometrically neglected, which includes children who receive very few of either type of nomination. The controversial children, who receive high numbers of both types of nominations, have more impact or prominence in the peer group than do neglected children, who receive low numbers of liked and disliked nominations. Finally, the last category is sociometrically average, which includes everyone who is not particularly high or low on either type of nomination.

BEHAVIORAL AND COGNITIVE CHARACTERISTICS OF STATUS GROUPS

Much research on sociometric status has focused on the rejected category (see Asher and Coie for a comprehensive review of peer rejection). The reason for this focus is that rejected children are most at risk for current and future behavioral problems. However, researchers have examined the behavioral characteristics and cognitive thought patterns of children in all these categories, as well as the antecedents and consequences of membership in a particular status group. What follows is a brief review of this research.

Five major sociometric statuses and their characteristics		
Status	Sociometric ratings	Characteristics
Popular	<ul style="list-style-type: none"> • Many well-liked ratings, few disliked ratings • Many positive ratings 	<ul style="list-style-type: none"> • Popular and have many friends • Viewed as leaders • Friendly and sociable • Cooperative and helpful • Understand social cues well and have high levels of social competence • Respect authority • Follow social rules • Described as having a good sense of humor and being positive
Controversial	<ul style="list-style-type: none"> • Both well-liked and disliked ratings • Ratings highly variable with many at each extreme 	<ul style="list-style-type: none"> • Disruptive and aggressive • Socially competent • Active • Disregard social rules • Viewed as leaders and as having an impact on peer group • Perceived as having both positive and negative attributes • Share characteristics of both the popular and rejected aggressive groups
Neglected	<ul style="list-style-type: none"> • Ratings are near the mean on scores of social preference and social impact • No extreme positive or negative ratings • This is the most unstable of statuses 	<ul style="list-style-type: none"> • Ignored or over looked by peers • Not treated poorly but not treated well by peers • Solitary and withdrawn • Not aggressive • Do not differ behaviorally from either the popular or average group
Average	<ul style="list-style-type: none"> • Ratings are near the mean on scores of social preference and social impact • No extreme positive or negative ratings 	<ul style="list-style-type: none"> • Perceived as neither popular nor unpopular • High levels of positive social behaviors • High levels of social competence
Rejected	<ul style="list-style-type: none"> • Many disliked and very few well-liked ratings • Many negative ratings 	<ul style="list-style-type: none"> • Associated with future maladaptive behaviors • Difficulties reading social cues <ul style="list-style-type: none"> • Perceived as bossy, non-cooperative, and impulsive
<i>Rejected aggressive</i>		<ul style="list-style-type: none"> • Aggressive and disruptive • Viewed as bullies • Externalize problems
<i>Rejected withdrawn</i>		<ul style="list-style-type: none"> • Perceived as sad and depressed • Do not actively engage in classroom activities • Have high negative self-perceptions • Actively ignored by classmates and often victims of bullying

Researchers have determined behavioral profiles for the various status categories, and this research is nicely summarized in a review article by Newcomb, Bukowski, and Pattee. Sociometrically popular children tend to be helpful, cooperative, sociable, and demonstrate leadership within the peer group. Sociometrically rejected children tend to fall into two subgroups: rejected-aggressive and rejected-withdrawn. Rejected-aggressive children are physically aggressive and bullying toward peers, while rejected-withdrawn children are often the victims of aggression by other children. Both groups display maladaptive behavior that makes it difficult for these individuals to get along with other children. Controversial children share characteristics with both popular and rejected children. They are very active in the peer group and demonstrate leadership and cooperativeness, but they also tend to display aggres-

sion toward peers and do not abide by the rules. The neglected category is not stable over time; in other words, if a child is categorized as neglected during one measurement session, he or she is likely not to have that same status if measurements are taken several months or a year later. Although the neglected category may seem to be similar to the rejected-withdrawn group, there are important differences between the two. Rejected-withdrawn children are actively ostracized by the peer group, while neglected children are essentially ignored and not treated particularly well or particularly poorly by peers.

In addition to behavioral differences, children in the various status groups also differ in their patterns of thinking. Rejected-aggressive children tend to make hostile attributions regarding other children's behavior, whereas rejected-withdrawn children tend to make self-defeating

attributions that interfere with their ability to make friends. Also, rejected children are less accurate overall than are other status groups at interpreting peers' behavior. Popular and average children have higher levels of social competence and are able to achieve their goals more readily in social situations than are rejected children.

ANTECEDENTS AND CONSEQUENCES OF SOCIOMETRIC STATUS

As one might imagine, children in these different status categories have different prognoses for future success. Longitudinal studies that follow children as they grow older (such as the study by Hymel, Rubin, Rowden, and LeMare) and retrospective studies that look at the childhood experiences of adults have both shown that early peer rejection is associated with later mental health problems, criminal behavior, and early school withdrawal. Rejected-aggressive children are more likely to engage in impulsive and delinquent behavior, while rejected-withdrawn children are more likely to suffer from depression and anxiety. Rejected children as a whole display maladaptive behavior as early as infancy, demonstrating more difficult temperaments and more insecure attachment to parents than do those from other status groups.

It is very important to note that most of the research on antecedents and consequences of sociometric status has been correlational rather than causal in nature. In other words, researchers have not established that temperament and attachment problems or faulty thinking patterns cause sociometric rejection, nor have they established that being sociometrically rejected in school causes later problems in life. There might be other variables as yet uninvestigated which could be responsible for the child's status as well as his or her past and future problems. If there is not a causal relationship between status and these other variables, it means that helping children to be more accepted by their peers will not necessarily improve their outcomes later in life.

Furthermore, it is important to realize that the link between sociometric status and present and future problems may be moderated or weakened by other variables. For example, research on friendships (such as the study by Parker and Asher) shows that friendship and peer status are two independent constructs, and children may have close dyadic friendships regardless of their status in the overall peer group. Having such friendships can make adjustment much easier for rejected children, and not having such friendships can attenuate the positive effects of being sociometrically popular.

GENDER AND DEVELOPMENTAL DIFFERENCES

Sociometric status differs somewhat depending on gender and stage of development. Rejected boys are distinguished from popular boys primarily based on aggression levels, whereas popular and rejected girls differ primarily in the degree to which they cooperate with others. Boys tend to display more physical aggression, while girls display indirect or relational aggression (spreading rumors or excluding or ostracizing peers). From a developmental perspective, a number of researchers have examined the stability of sociometric status over time and have found that status remains fairly stable over a child's time in school and often carries over to a new school environment. More interesting from a developmental point of view is the way in which children's and adolescents' stereotypes about popularity change as they grow older. If status is measured by asking about peers' reputation ("Who is popular in the peer group?" or "Who is unpopular?"), the results are very different from the findings on sociometric status, especially for older children and adolescents. Peers whom children name as popular may have more in common with sociometrically controversial children than with sociometrically popular children. A cross-sectional study by LaFontana and Cillessen shows that peers with a popular reputation are more dominant, demonstrate both prosocial and antisocial behaviors, and possess more resources such as money, athletic ability, and physical attractiveness, than do sociometrically popular peers. The differences between sociometrically popular and perceived popular children increase with age, peaking in middle school and early adolescence. Girls reach this peak somewhat earlier than do boys.

CAVEATS AND FUTURE DIRECTIONS

Despite the massive amount of research on sociometric status, there are several limitations to this literature. Most of the research has focused on the United States, so researchers do not know whether the same principles hold true in other cultures. There is a heavy emphasis on the role of cognition because the cognitive perspective dominated developmental psychology during the 1980s and 1990s when much of this research took place. There is also a strong emphasis on the individual and how he or she is affected by sociometric status. Future research must focus more on dyads and groups as the units of analysis. Much of the research has taken place with racially undiverse populations. Only in the early part of the twenty-first century did researchers begin in earnest to explore gender and ethnic differences in sociometric status. Finally, interventions depend on whether researchers view certain behaviors as adaptive or maladaptive. For example, is the aggression that reputationally popular children display considered good (assertiveness) or bad (bullying)? Should

it be encouraged or discouraged? Parents, teachers, and researchers must work together to determine the future direction of research on sociometric status.

Kathryn M. LaFontana

PEER TUTORING

Peer tutoring is an intervention in which students work in pairs to master academic skills or content. Peer tutoring can involve partners who are the same age or different ages (cross-age). Cross-age peer tutoring involves older students serving as tutors for younger, lower-functioning students. Cross-age tutoring occurs, for example, when students in a high school child development class spend regularly scheduled time each week reading with struggling students in a fourth grade class. In this instance, the tutors might be expected to gain less from the content being tutored but may be expected to gain more in social responsibility or understanding of learning as a process.

In same-age tutoring, in which students of the same age tutor each other, more skilled students may be paired with less skilled students. In this case, students with stronger skills may provide the first responses, providing a model for the less skilled partner. In other cases, the teacher may decide to pair students of similar ability and have them alternate tutoring roles, which is sometimes referred to as reciprocal peer tutoring. Class-wide Peer Tutoring (CWPT) occurs when the teacher creates highly structured tutoring materials for use during the tutoring session. Peer tutoring is differentiated from tutoring between adults, such as community volunteers, and students. It is also distinguished from cooperative learning, in which students work collaboratively in groups.

Clearly, peer tutoring is a general term that encompasses many tutoring models. All methods are designed to increase practice, responding, and feedback for students, and they often result in increased student motivation and achievement. These models differ, however, in how tutoring pairs are assigned, how tutoring content is developed, and how extensively the tutoring is employed. For example, in cross-age tutoring the expert tutor is typically the older student, while in reciprocal peer tutoring and CWPT the paired students are the same age and can take turns assuming the expert role. In cross-age and reciprocal tutoring, the student tutor is typically responsible for learning the content and then teaching the information to the tutee, while in CWPT the teacher is more responsible.

The instructional components of the peer tutoring model include: (a) explicit teaching of students in how to be tutoring experts, (b) purposeful partner assignment, (c) careful preparation of tutoring materials, (d) highly structured tutoring procedures that include specific feedback for tutors to provide tutees, (e) expert role reversal, and (f) active teacher monitoring. Also, some type of systematic performance is typically included. Explicit teaching of students in how to be tutoring experts can include modeling examples and non-examples of appropriate tutoring interactions, posting tutoring guidelines as reminders for students, giving feedback on how well students are meeting expectations for tutoring, and re-teaching procedures as necessary. Partner assignment can be based on student academic skills, tutoring activity content, and/or interpersonal relationships between students. Preparing tutoring materials carefully is necessary to ensure success in the tutoring experience and may include differentiation of materials. Materials typically include highly structured tutoring procedures that indicate how tutors can determine if a response is correct and how to respond to both correct and incorrect responses. Finally, teachers actively monitor peer tutoring and may give feedback to students both on content and procedures.

Peer Assisted Learning Strategies (PALS) is one peer tutoring activity that has been researched for grades kindergarten through 12. This tutoring program is designed to help students improve in reading and other academic skill areas. The steps to the program for reading are: (a) predicting, (b) partner reading, (c) retelling, and (d) summarizing. In this program, the stronger reader is the expert tutor. Students begin by making a prediction about the passage they are about to read. They then take turns reading the same passage with the stronger reader going first. Then the stronger reader prompts the weaker reader to retell the passage and then summarize the information with the following steps: (a) "Name the who or what the passage is about," (b) "Tell the most important thing about the who or what," and (c) "Say the main idea in 10 words or less." A modified version of this peer tutoring model has also been used in mathematics.

Another example is peer tutoring with differentiated instructional materials targeted toward classrooms with students of different learning needs. Differentiation of materials can include: (a) differential practice time, (b) embedded strategic information, and (c) increasing levels of difficulty. Differential practice time allows for students to have as much time needed to master a concept before proceeding to the next skill set. Embedded strategic information can include specific strategies for improving memory or comprehension of important concepts, such as mnemonic strategies or comprehension questioning. Increasing levels of difficulty might include varying levels of supports that can be provided to students on an as needed basis. For example, students can begin with identification formats (in which they are asked to identify the correct response from an array) and advance to production formats (in which they produce the correct response independently) or to answering tutor questions under prompted or non-prompted conditions.

Peer tutoring models were applied systematically as early as 1789, but they gained popularity in toward the end of the twentieth century, with accumulating research evidence in support of the practice. Learning gains commonly observed in peer tutoring programs are generally attributed to increased active academic engagement and opportunities to respond on the part of students, particularly in contrast to models in which all instruction is delivered by the teacher or by independent seat work. Peer tutoring has been studied in many academic areas, including science and social studies, in addition to skill areas such as reading and spelling. Peer tutoring has also been effectively implemented in classrooms that include students with diverse learning needs, such as students with disabilities and students for whom English is a second language.

Academic gains have been consistently observed in peer tutoring programs, with treatment effects in the medium to high range for both tutors and tutees. Effects have also been observed for students acting as tutors in the role of expert. Social benefits of peer tutoring, including improved self-esteem and self-efficacy, improved attitude toward school, and improved interpersonal functioning, are commonly reported anecdotally. Research support for these more general outcomes has been inconsistent, although students commonly improve in their attitude toward the content being tutored and in their attitude toward their tutoring partner. Teachers who have implemented peer tutoring typically respond favorably to the practice.

PIAGET, JEAN **1896-1980**

Jean Piaget was born in 1896 in Neuchâtel, Switzerland, and died in Geneva in 1980. He graduated from the University of Neuchâtel in 1918 as a Doctor of Natural Sciences with a dissertation on mollusks, but he had always been deeply interested in philosophy. Subsequently, he studied psychology, logic, and philosophy of sciences in Zurich and at the Sorbonne in Paris. He held various professorships in sociology, philosophy of sciences, history of scientific thought, experimental psychology, and developmental psychology at the Universities of Neuchâtel, Geneva, and Lausanne, and the Sorbonne, but his research interest starting in the 1920s was in epistemology. He is often viewed as a psychologist,

Jean Piaget ARCHIVES OF THE HISTORY OF AMERICAN PSYCHOLOGY. THE UNIVERSITY OF AKRON.

but child psychology for him was a means for answering epistemological questions such as: How do we know what we think we know, and how did humanity build knowledge since its prehistoric beginnings? As a scientist, he insisted that such questions had to be answered scientifically, but historical evidence was no longer available. He studied children's construction of knowledge because children furnished empirical data that seemed most relevant to humanity's construction of knowledge.

PIAGET'S CONTRIBUTION TO THE PSYCHOLOGY OF CLASSROOM LEARNING

Piaget made many contributions to the psychology of classroom learning. Two will be highlighted here. One is his constructivism, the theory that states that human beings acquire knowledge and moral values by constructing them from the inside in interaction with the environment, rather than by internalizing them directly from the environment. Young children's construction of language illustrates the constructive process. Because most American children learn English, and most French children learn French, it is easy to think that children learn language by internalization from their environment. When one looks more carefully,

however, one finds that babies begin by uttering one word such as "Ball!" and go on to say two words, such as "Ball gone." By the time they go to school, children utter sentences like "I thought it in my head." These examples cannot be said to have been acquired by internalization because no one in the environment talks in these ways.

In the moral realm, too, most adults in the early 21st century believe that moral values and rules are acquired by direct internalization from the environment. However, Piaget showed that moral values, too, are constructed by each child from the inside in interaction with the environment. For example, he asked 6-to-14-year-olds why it was bad to tell lies. Young, heteronomous children replied, "Because you get punished when you lie." By contrast, older, more autonomous children tended to say that lies are bad even when one is not punished for them because lies destroy the bond of trust. The importance of mutual trust is an example of a moral value that has been constructed from the inside. For older, more autonomous children, lies are bad independently of reward and punishment.

Many psychologists think that Piaget's major contribution was the stages of development he found, but the stages are important only because they furnish the evidence that supports constructivism. Many bits of knowledge and morality can be learned by internalization, but this learning is often superficial and/or temporary.

An important part of Piaget's constructivism is his epistemological position against empiricism.

For centuries, philosophers had been arguing about the truth of two major epistemological traditions: empiricism and rationalism. Piaget's sympathy was with the rationalist side of the fence as can be seen in the conservation-of-number task. In this task, if the child uses one-to-one correspondence to put out as many chips as the interviewer has aligned, the interviewer says, "Watch what I am going to do," and moves the chips to make one of the rows look longer than the other. The crucial question then put to the child is: Are there as many chips in my row as in your row, or are there more in yours, or more in mine? Nonconservers usually say that the longer row has more because it looks like more. Nonconservers thus base their judgments on the empirical knowledge of what they can see. When their logico-mathematical knowledge later becomes stronger, they begin to deduce logically that the two rows have to have the same number.

Piaget's method of data collection must be noted here. At a time when only standardized questions were considered to be "objective" and "scientific," he invented the "clinical method," arguing that researchers must probe into each child's reasoning to get valid data. For example, if a child gave the correct answer in the conservation-of-number task,

Piaget believed that the interviewer should ask, “How do you know (that the two rows have the same number)?” If the child’s response was “I just knew it,” he further probed into the child’s reasoning to ascertain the strength of his or her logic.

A second major contribution Piaget made to the psychology of classroom learning is his conceptualization of autonomy as the aim of education. In his theory, autonomy does not mean the right to make decisions. It means the ability to make decisions by taking relevant factors into account, independently of reward and punishment. These decisions are about right and wrong in the moral realm, and about truth and untruth in the intellectual realm. Autonomy is the opposite of heteronomy, which means being unable to make decisions for oneself and therefore being governed by others. For an autonomous person like Copernicus, the heliocentric theory had to be promulgated even though it was rejected by his fellow scientists.

Schools are now generally run with ready-made rules and curricula supported by reward and punishment, as if heteronomy (obedience) were the aim of education. Piaget’s theory has changed some classroom practices in the early grades, but its influence is yet to take roots. When educators adopt moral and intellectual autonomy as the aim of education, schools will be run very differently and produce graduates with a strong sense of responsibility about themselves as well as the welfare of others. Schools will also endeavor to produce thinkers capable of creating new knowledge rather than merely repeating what others have said.

Constance Kamii

PINTRICH, PAUL ROBERT 1953–2003

Paul Pintrich was born on November 4, 1953. He died of a heart attack July 12, 2003, while riding with a group of bicyclists on the road back from Hell, Michigan.

Pintrich received a B.A. in psychology from Clark University in 1975 and a Ph.D. in education and psychology from the University of Michigan in 1982. He remained at Michigan until his death, rising through the ranks to become professor and chair of the Combined Program in Education and Psychology and associate dean for research in the School of Education.

Although Pintrich died before reaching the age of 50, he was unusually productive, publishing well over 100 articles and book chapters as well as coauthoring or co-editing nine books. He was an excellent mentor and colleague, publishing with many collaborators in the United States and abroad. He helped build bridges to psychology in Europe, participating in the European Association for Research in Learning and Instruction (EARLI) and serving as president of the Division of Learning, Instruction, and School Psychology of the International Association of Applied Psychology. His professional service also included the editorship of the *Educational Psychologist*, the presidency of APA Division 15 (Educational Psychology), and president of the AERA Special Interest Group on Motivation.

In the early 1980s Pintrich and Wilbert J. McKeachie developed one of the first courses in Learning to Learn. This course differed from traditional study skills courses in that students not only learned strategies for learning but also learned the cognitive and motivational theories that underlie student learning so that they could apply the theories in new learning situations (Pintrich, McKeachie, & Lin, 1985). Followup studies showed that the course improved learning in later courses (McKeachie, Pintrich, & Lin, 1985). An outgrowth of that work was the development of the Motivated Strategies for Learning Questionnaire (MSLQ), which was used all over the world (Pintrich, Smith, Garcia, & McKeachie, 1991).

Beginning with studies of student self-efficacy (Pintrich & Blumenfeld, 1985), Pintrich was soon writing about the dynamic interactions between cognition and motivation in learning (Pintrich, 1988, 1989, Marx, & Boyle, 1993). In their seminal research on self-directed learning, Pintrich and his wife, Elizabeth De Groot, integrated cognitive, motivational, and behavioral factors affecting learning (Pintrich & De Groot, 1990). Well before self-regulation became a major research area, Pintrich was publishing research and theory that formed a foundation for later work. He and his students expanded the original cognitive approach to self-regulation to

include regulation of motivation and emotion as well (Garcia & Pintrich, 1994; VanderStoep, Pintrich, & Fagerlin, 1996).

Shortly thereafter Pintrich and his students became involved in research on goal theory. Their work was designed to answer questions such as the following: Are students primarily studying to get a good grade or is their primary goal to gain a good understanding of the subject? Are they more concerned with doing better than other students (performance motivation) than with mastering the subject (mastery motivation)? Although goals are usually thought of in positive terms, Pintrich and his collaborators also looked at avoidance goals (Zusho & Pintrich, 2000).

In later years Pintrich and Barbara Hofer (his student) began studying epistemological beliefs. Their paper “The development of epistemological beliefs: Beliefs about knowledge and knowing and their relation to learning” (Hofer & Pintrich, 2002) won the AERA award for best review article of the year.

Pintrich was a pioneer in developing an integrated theory of motivation and cognition and in showing how classrooms influence the development of student motivation for learning. He was one of the world’s leading scholars in the area of student motivation, cognition, and self-regulation.

PORTFOLIO ASSESSMENT

Portfolio assessment is an evaluation tool used to document student learning through a series of student-developed artifacts. Considered a form of authentic assessment, it offers an alternative or an addition to traditional methods of grading and high stakes exams. Portfolio assessment gives both teachers and students a controlled space to document, review, and analyze content learning. In short, portfolios are a collection of student work that allows assessment by providing evidence of effort and accomplishments in relation to specific instructional goals (Jardine, 1996). At its best, portfolio assessment demands the following: clarity of goals, explicit criteria for evaluation, work samples tied to those goals, student participation in selection of entries, teacher and student involvement in the assessment process, and self-reflections that demonstrate students’ metacognitive ability, that is, their understanding of what worked for them in the learning process, what did not, and why. These elements enhance the learning experience and the self-understanding of the student as learner.

ASSUMPTIONS AND PROCEDURES

Portfolio assessment is not defined by a single procedure, nor is there a single best way to use portfolios. However, the following components are generally assumed integral. The portfolio itself is a container of some sort, for example, a folder, crate, file, or virtual space for online portfolios. The selected contents should demonstrate student accomplishments over time. All selections and parts are authentic in that the included pieces provide evidence that the goals and objectives of the curriculum have been met, with added student reflections that review the process and /or products of learning. Participants in the portfolio assessment process (instructors, students and parents or administrators, if applicable), should be aware of assessment standards in advance. Depending on the type of portfolio, the contents may vary widely. Possible contents include writing samples that may vary in genre, content, and style, laboratory reports, journals, taped performances, recordings, art, research papers, projects, photos, interviews, conferences, tests, quizzes, observations, and reflections.

In some schools, material from a semester’s or year’s portfolio is digitalized and stored for future reference as a record of student accomplishments over a specified time. Colleges requiring licensure for a profession may require students to keep evidence of each standard met in an online or physical portfolio, ensuring ready access to reviewers or accrediting agencies that all work has been completed. Because a portfolio contains a variety of artifacts that provide evidence of work completed, it is particularly useful in these assessment circumstances.

KEY ELEMENTS FOR EFFECTIVE PORTFOLIO ASSESSMENT

Clear criteria for evaluation, including what must be included in the portfolio and rubrics for evaluation, are vital to successful portfolio assessment. When teachers develop unambiguous assessment criteria, they necessarily use a shared discourse, clarify beforehand any unfamiliar vocabulary (Rodgers, 2002), and assure that they and students have a mutual understanding regarding the theoretical foundations of the task before it takes place. Understanding these criteria can help reduce or eliminate criticism about subjectivity or unfairness of grading, a common criticism of those who prefer standardized assessments. The use of comprehensive rubrics that present structured information about organization, required components, length and content of entries and reflections, in addition to any specific assignment rubrics that clearly outline the goals, obligations, and constraints of particular entries, are valuable. The more precise and comprehensive the rubric, the more objective the assessment. Through explicit direction, instructors should make clear all guiding principles or policies for what may or may not be included in the portfolio.

Reflective pieces require students to articulate and review components of the portfolio and are a part of a comprehensive assessment. Reflections allow students the time and space to analyze their achievement in relation to class standards, evaluate their final products, and determine growth as well as needs (Fernsten & Fernsten 2005). The metacognitive exercise of figuring out how they know what they know about the learning that has taken place can be an invaluable learning tool and helps participants take responsibility for their own learning.

TYPES OF PORTFOLIOS

There are a variety of portfolio types, each designed to help assess either the process or the products of learning.

Showcase portfolios. Showcase portfolios highlight the best products over a particular time period or course. For example, a showcase portfolio in a composition class may include the best examples of different writing genres, such as an essay, a poem, a short story, a biographical piece, or a literary analysis. In a business class, the showcase portfolio may include a resume, sample business letters, a marketing project, and a collaborative assignment that demonstrates the individual's ability to work in a team. Students are often allowed to choose what they believe to be their best work, highlighting their achievements and skills. Showcase reflections typically focus on the strengths of selected pieces and discuss how each met or exceeded required standards.

Process portfolios. Process portfolios, by contrast, concentrate more on the journey of learning rather than the final destination or end products of the learning process. In the composition class, for example, different stages of the process—an outline, first draft, peer and teacher responses, early revisions, and a final edited draft—may be required. A process reflection may discuss why a particular strategy was used, what was useful or ineffective for the individual in the writing process, and how the student went about making progress in the face of difficulty in meeting requirements. A process reflection typically focuses on many aspects of the learning process, including the following: what approaches work best, which are ineffective, information about oneself as a learner, and strategies or approaches to remember in future assignments.

Evaluation portfolios. Evaluation portfolios may vary substantially in their content. Their basic purpose, however, remains to exhibit a series of evaluations over a course and the learning or accomplishments of the student in regard to previously determined criteria or goals. Essentially, this type of portfolio documents tests, observations, records, or other assessment artifacts required for successful completion of the course. A math evaluation portfolio may include tests, quizzes, and written explanations of how one went about solving a problem or determining which formula to use, whereas a science evaluation portfolio might also include laboratory experiments, science project outcomes with photos or other artifacts, and research reports, as well as tests and quizzes. Unlike the showcase portfolio, evaluation portfolios do not simply include the best work, but rather a selection of predetermined evaluations that may also demonstrate students' difficulties and unsuccessful struggles as well as their better work. Students who reflect on why some work was successful and other work was less so continue their learning as they develop their metacognitive skills.

Online or e-portfolios. Online or e-portfolios may be one of the above portfolio types or a combination of different types, a general requirement being that all information and artifacts are somehow accessible online. A number of colleges require students to maintain a virtual portfolio that may include digital, video, or Web-based products. The portfolio assessment process may be linked to a specific course or an entire program. As with all portfolios, students are able to visually track and show their accomplishments to a wide audience.

BENEFITS OF PORTFOLIO ASSESSMENT

Portfolio assessment research substantiates the idea that students greatly benefit from assessments that go beyond

simple letter grades and involve participants in the evaluation process. By taking part in the development of their portfolios, analyzing the criteria for what constitutes good work, and learning to evaluate their own work through guided reflective practices, students grow and develop in their knowledge and understandings. Portfolio assessment is part of a substantial body of research documenting the student benefits that emerge from an awareness of the processes and strategies involved in learning. (Hamp-Lyons & Congdon, 2000; Martin-Kniep, Cunningham, Feige, 1998)

The benefits of portfolio assessment are numerous. To begin with, they are a more individualized way of assessing students and have the advantage of demonstrating a wide range of work. They may also be used in conjunction with other types of required assessments, such as standardized or norm referenced tests. Often, portfolio contents are selected collaboratively, allowing students an opportunity to make decisions about their work and encouraging them to set goals regarding what has been accomplished and what needs further work, an important skill that may serve them well in life endeavors.

Portfolio assessment can promote a dialog between teacher and students about the individualized nature of the work. Too often, students may have papers or projects returned with a number or letter grade only and fail to understand what might be necessary for improvement. Required reflections in conjunction with conferencing reduce the possibility that students will be unclear about the assessment or what must be done to make improvements. This one-to-one aspect is an additional bonus for those students who may be too shy to initiate conversations with instructors as well as for those who enjoy speaking about their work and may better understand what worked and what did not through a verbal exchange.

Most importantly, portfolio assessments provide an authentic way of demonstrating skills and accomplishments. They encourage a real world experience that demands organization, decision making, and metacognition. Used in a thoughtful, carefully planned way, portfolio assessment can foster a positive outlook on learning and achievement.

POSSIBLE SELVES THEORY

Self-concept is one's theory about oneself, the person one was in the past, is now, and can become in the future, including social roles and group memberships. A well-functioning self-concept helps make sense of one's present, preserves positive self-feelings, makes predictions about the future, and guides motivation. The contents of the future-oriented component of self-concept have been termed *possible selves* (Markus & Nurius, 1986). Possible selves are the selves one believes one might become in the near and the more distal future and are therefore important in goal setting and motivation (for a review, see Oyserman & James, in press). Possible selves are valenced; that is, each individual has both positive images of the selves he or she desires and expects to become and negative images of the selves he or she wishes to avoid becoming.

While current self-concept focuses on who one is now, by focusing on the future, possible selves allow for self-improvement, malleability, and personal growth. They provide a chance to experiment with and try on various potential futures ("Maybe I'll be a teacher or maybe I'll be a nurse. What would it be like to become a teacher or a nurse? How would I get there? What are the stages and obstacles along the way?"). The future is the target of much of our efforts as individuals. Homework is done and broccoli is eaten all in pursuit of some future state. As noted by Oyserman & James (in press), doing or not doing homework one night really does not make that much difference, but if each night's homework is viewed in this way, homework will rarely get done and that does matter. Whether one eats or does not eat the potato chips with lunch today does not make or break one's likelihood of being overweight, but, over time, each of these small choices adds up. In this sense, current actions are taken due to individuals' beliefs about their consequences in the future. Generally speaking, individuals are motivated to reduce the gap between their present and future positive possible selves while increasing the gap between their present and future negative possible selves.

Because possible selves provide both positive images of one's self attaining future goals and negative images of one's self failing to attain these goals (and of the feared selves one might become instead), possible selves are an integral part of a well-functioning self-concept. By focusing on the future, possible selves can improve well-being and optimism about the future. Things may not be going well now, but a possible self suggests the promise of change. Possible selves can improve one's ability to self-control and self-regulate because possible selves help one to focus on goals and lessen the influence of distractions in one's social world. Possible selves are most likely to improve self-regulatory ability when they are salient, linked with strategies, feel congruent with other aspects of self-concept, and when difficulty attaining them feels like proof one really cares rather than evidence for withdrawing effort (Oyserman & James, in press).

In terms of content, school-focused selves are common in childhood and adolescence regardless of socioeconomic status (for a review, see Oyserman & Fryberg, 2006). School-focused possible selves describe positive expectations regarding one's school success and academic attainment, including specific, immediate goals such as passing eighth grade or not failing the math test and more general long-term views such as being smart or getting a GED (Oyserman, Bybee, Terry, & Hart-Johnson, 2004). Youth are likely to have multiple, potentially competing possible selves, not all of which will influence behavior at any particular point in time (Oyserman & James, in press).

DEVELOPMENT OF POSSIBLE SELVES: INDIVIDUAL AND CONTEXTUAL FACTORS

Possible selves are influenced by both individual and contextual factors. Others can serve as role models and anti-models for both positive and negative possible selves. These others can be particular individuals with whom one has a relationship or simply a general sense of what others like oneself have been able to do.

Past Experiences. One's own past experiences of success or failure in a domain clearly influences one's beliefs about the relevance or attainability of possible selves in that domain as well as one's ability to articulate strategies to work on the possible self. Past failures may make it harder to articulate both what success would look like in a particular domain and which strategies are likely to be effective. Past successes may make it easier to articulate both what success would look like and which steps are needed to attain a desired possible self. For example, youth with a history of juvenile delinquency and school failure are less likely to articulate education and job focused possible

selves, students from low income families are less likely to generate multiple strategies for how to attain school-focused possible selves like doing well and getting good grades (Oyserman & Fryberg, 2006; Oyserman & James, in press; Oyserman & Markus, 1990).

Developmental Context. Content of possible selves reflects developmentally relevant self-tasks. During the school years, these tasks focus on being competent in school, being connected to others, and developing a sense of self. Not surprisingly, common possible selves are focused on school, relationships and avoiding becoming off-track such as using drugs or becoming pregnant (Oyserman & Fryberg, 2006). With development, the focus of these tasks evolves. College students and young adults are focused on occupational, educational, and interpersonal possible selves (such as getting married), whereas family and parenting possible selves become more important in young and middle adult years. As adults age, job-focused possible selves recede and physical health related possible selves become more prominent. However, some possible selves persist even when they are not easy to attain (for a review, see Oyserman & James, in press).

Social Context. Possible selves are also influenced by others' expectations and by historical and sociopolitical contexts. Some social contexts provide easy access to role models and reminders to focus on school while other contexts rarely provide these cues. Minority, low-income, and rural youth may be less able to imagine school-focused possible selves or to sustain these possible selves if their contexts include few models of overcoming barriers to success or are rife with stereotypes that are not congruent with school-focused possible selves. Research has shown that if going to college does not feel like an option as early as middle school, students withdraw academic effort (Oyserman & Fryberg, 2006; Oyserman, Gant, & Ager, 1995).

ASSESSING POSSIBLE SELVES

This section draws heavily from the review of measures and measurement strategies presented in Oyserman and Fryberg (2006). Oyserman and Fryberg (2006) provide specific references for both close- and open-ended measures used to assess possible selves and the interested reader is referred to their more detailed discussion.

Close-Ended Measures. Respondents are provided a list of possible selves and either asked to check off which possible selves are relevant or rate their likelihood of attaining each possible self or sort and rank the importance of these possible selves. Close-ended measures are easy to code but require preparation to be sure that the content is relevant to the sample of interest. Moreover,

with close-ended measures, one can only learn how much respondents endorse the items provided, not what they would have said given free rein. Though past research results can form a basis, to make sure that content is relevant, pilot work is needed. Given the potential diversity of possible selves, a pre-set checklist may not accurately reflect content of possible selves.

Open-Ended Measures. Open-ended tools typically open with a brief statement of what possible selves are and ask respondents to generate their own possible selves and, where relevant, their strategies for attaining them. The strengths of an open-ended measure are that it allows participants to describe their possible selves without constraint and that the format is easily adapted to different groups and contexts. The limitations of this method are that it requires content-coding of responses and generating one's own responses (rather than simply endorsing a pre-set list as is done in the close-ended method) is likely to be more effortful.

MOTIVATIONAL CONSEQUENCES OF POSSIBLE SELVES ON CHOICE, PERSISTENCE, ACHIEVEMENT

The future is an important component of self-concept and doing well in school is a common element of youths' future possible selves (Oyserman & Fryberg, 2006). In their review, Oyserman and Fryberg report on studies linking possible selves with reduced risk of substance use and sexual activity. Thus, sixth through ninth graders with fewer positive possible selves were more likely to report cigarette smoking and alcohol consumption and eighth graders whose possible selves focused on being popular rather than academic success were more likely to report smoking and drinking alcohol in the ninth grade. Seventh grade African American boys reported less initiation of sexual activity after participating in an intervention to develop possible selves.

However, possible selves do not always sustain self-regulatory action. Youth do fail algebra and engage in risk-taking behavior. Possible selves succeed in focusing effort when they are linked to behavioral strategies, they feel congruent with important social identities, and they are balanced so that difficulty working on the possible self is not construed to mean that the possible self is unimportant (much as the 'no pain, no gain' metaphor in sports, see Oyserman, et al., 2006). Each of these issues is described below.

Strategies to Attain Possible Selves. Imagining what is possible for one's future can increase optimism, but articulating a possible self is not enough to produce sustained effort and behavior change. For that to occur, possible

selves need to be linked with specific strategies (Oyserman et al., 2004). Strategies are concrete behaviors such as studying or setting an alarm clock. Strategies help one to focus on goals while anticipating and planning for setbacks by developing plans of action and fall back plans. In one study, by the end of the school year, students whose school-focused possible selves included detailed strategies reported feeling more efficacious; results were not limited to positive feelings, according to school records, students with strategies attained better grades than those without them (Oyserman et al., 2004). In another study, an intervention increased students' possible selves and strategies to attain them succeed in improving outcomes, including grades and in-class behaviors, even when other conditions suggested risk of school failure (Oyserman, Brickman, Rhodes, 2007).

Social Identity. One is more likely to engage in strategies to attain a possible self when the possible self and the strategies feel congruent with one's important social identities (e.g., racial-ethnic, gender, social class). Otherwise, the possible self itself or working on attaining the possible self will feel like it conflicts with the rest of who one is. For example, if boys believe that only girls raise their hands to participate or do their homework or stay after class for help, they are less likely to engage in these activities, even if they believe that these strategies would help them attain school-focused positive possible selves (for the general model, see Oyserman, et al., 2006).

The Carrot and the Stick: Balance in Possible Selves. It is tempting to focus only on the positive since thinking about how things can go wrong may feel discouraging. However, focusing on both positive and negative possible selves in the same domain improves focus and is associated with better outcomes. Balanced school-focused possible selves occur when one has both a positive possible self (e.g., going to college) and a feared or to-be-avoided possible self (e.g., being an unemployed drop-out) in the same domain (Oyserman, et al., 2006). Having both images serves as a carrot and a stick, simultaneously reminding the student of the goal (the carrot) and of where the student may end up if effort is not sustained (the stick). Students with school-focused balance in possible selves are less likely to be involved in delinquent activities (Oyserman & Markus, 1990) and are more likely to attain better grades (Oyserman et al., 2006), and the presence of balance in possible selves may be particularly important in social contexts in which one is likely to encounter obstacles to achieving one's goals.

IMPLICATIONS OF POSSIBLE SELF THEORY FOR TEACHERS

Teachers, parents, and students all have possible selves images of how things might be in the near and more distal future. These images illustrate that change is possible. Possible selves can undergird self-improvement by showing a path toward the future and by highlighting where one might end up if effort is not maintained. Intervention to help teachers, parents, and students focus on what they want to become and avoid becoming, what they value, and how they expect to engage in becoming like their desired selves and avoiding becoming like their undesired selves can be highly effective. Indeed, the theory of possible selves has been used to understand progress and life transitions for both youth learners and adults in continuing education and other settings.

Perhaps the most important message that educators can take from the research on possible selves is that possible selves are malleable and can be influenced by intervention to enhance the content of possible selves. Changing possible selves through intervention can lead to positive changes in academic behavior, in better academic performance and lower risk of depression (Oyserman et al., 2002; 2006). Of particular note is the School-to-Jobs (STJ) intervention that focused explicitly on improving academic outcomes by changing possible selves. STJ was tested both as an after-school and an in-school intervention, running twice per week for six weeks so that it was completed by Thanksgiving break.

Each STJ session focused on developing an aspect of possible selves. Beginning sessions linked school-focused possible selves to important social identities (e.g., gender or racial-ethnic groups), linked proximal possible selves (e.g., graduating from eighth grade) to desired but distant adult possible selves (e.g., going to college, getting a good job), discussed how possible selves are influenced by role models, and linked present action to possible selves. Later sessions focused on identifying specific strategies to be enacted in the present that would help youth obtain their possible selves. Students articulated how they would cope with difficulty that they might encounter in attaining their desired possible selves. Program activities involved individualized activities such as creating a timeline into one's future, active participation by students, and group exercises. Two final sessions involved parents, with the goal of providing youth and parents structured activities in which to talk about possible selves and strategies to attain them (see Oyserman et al., 2006). Evaluation indicated that STJ successfully improved time spent engaged in strategies (e.g., improved in-class behavior, time spent doing homework) and long-term academic attainment, as measured by standardized test scores and attendance (Oyserman et al., 2004; Oyserman et al.,

2002). Additionally, participation in STJ reduced participants' depressive symptoms (Oyserman et al., 2006) and buffered youth from the negative effects on grades and behavior of low parent involvement in school (Oyserman, et al, 2007). Effects were sustained through two years of follow-up assessment. In sum, possible selves are useful as descriptive and predictive tools and can be modified by in-school activities resulting in significant long-term benefits for children.

PRAISE

The word praise originates from the Latin verb *pretiare*, meaning to highly value. The seminal work on the use of praise within the classroom context was produced by J. Brophy who defined praise as "commending the worth

of' or "to express approval or admiration" (1981, p.5). J. Thomas (1991) used the term "descriptive reinforcement" to describe praise. He outlined a three stage model for providing praise in the classroom as follows: (a) personalize the praise by using the student's name, (b) use one of 110 praise statements, and (c) outline what the student did to merit being praised. P. C. Burnett (2001) referred to Thomas's 110 statements as general praise noting examples such as "that's great," "well done," "terrific job," and "that's fantastic." In summary, teacher praise involves positive words, accompanied by positive affect, and as such is a targeted, affective response to students' behaviors or performance.

The term feedback is often used alongside praise but is quite different. Feedback is used to guide students in ways to improve their performance by providing information about their ability or inability to achieve success (Hattie, 1993). One type of feedback is attributional feedback. Teachers who note that students' success is attributed to their hard work are providing effort feedback (for example, "Tim, your great results reflect your hard work"), while teachers who ascribe success to ability (for example, "Great result, Rachel, you are clever at math") are providing ability feedback. Effort and ability feedback are referred to as attributional feedback because they attribute success and performance to either effort or ability.

EFFECTIVE AND INEFFECTIVE PRAISE

Brophy conducted a functional analysis of praise in the classroom and noted that teachers' verbal praise did not equate to positive reinforcement because praise was typically used infrequently, without reference to specific behaviors and often without credibility and sincerity. Brophy noted that classroom research suggested that only 6% of interactions involved praise, and he concluded that high rates of praise were not evident in classrooms. Brophy described 12 guidelines for both effective and ineffective praise.

The key ingredients for effective praise according to Brophy (1981) are:

Praise should be delivered in response to a specific behavior.

The behavior, deserving of praise, should be described in specific terms.

Praise should be sincere, credible, and spontaneous.

Praise should reward the attainment of clearly defined and understood performance criteria.

Praise should provide information about the student's competencies.

Praise should be given in recognition of noteworthy effort or success at a difficult task for that particular student.

Praise should attribute success to effort and ability implying that similar success in the future.

Ineffective praise:

Is delivered randomly or unsystematically,

Is restricted to global positive reactions delivered in a bland fashion with minimal attention to the student or behavior,

Rewards participation unrelated to performance,

Compares the student's performance to other students,

Is given without regard to the effort needed to complete the task,

Attributes success to ability alone or to external factors such as luck or the ease of the task, and

Is given by the teacher who acts as a power figure and external authority in a manipulative manner.

Not all of the literature is supportive of the use of praise in the classroom even when used effectively. R. Hitz and A. Driscoll (1994) noted literature that suggested that praise led to low expectations of success, discouraged children from judging for themselves, created anxiety, invited dependency, evoked defensiveness, and was delivered in the context of a power relationship. The major concern expressed was that praise was intrusive and controlling. Hitz and Driscoll advocated giving encouragement not praise and hence the mantra, encourage don't praise, emerged and formed part of many teacher training programs.

There has also been some debate regarding the use of ability feedback by teachers following a student's success. Brophy's guidelines noted ability feedback in the effective list but also noted a limitation by including the use of ability feedback alone in the ineffective list. Those who advocate the use of ability feedback highlight the impact that it has on the formation and development of students' self-concept (Craven, Marsh, & Debus, 1991). In addition, D. H. Schunk (1983) and B. Weiner (1986) noted that ability feedback produced higher expectations for future performance, greater skill acquisition, higher self-concept, enhanced satisfaction with performance, and further striving for achievement. Opposing the use of ability feedback in the classroom was C. M. Mueller and C. S. Dweck (1998) who argued against its use when they found that students who faced failure after receiving ability feedback showed low effort, poor persistence at a task and high frustration due to attributing their poor performance to lack of ability. Of further interest is the

fact that the use of effort feedback in the classroom has limitations. J. Henderlong and M. R. Lepper (2002) noted that the positive impact of effort feedback might be restricted if effort is overemphasised and the student perceives this as an indication that they lack ability and have to work hard to get anywhere. Furthermore, providing effort feedback may also be negative if hard work and effort result in failure.

DEVELOPMENTAL DIFFERENCES

Burnett (2001) investigated 747 elementary students' preferences for classroom praise. The students were in grades 3 to 7 and aged 8 to 12 years. Students reported that they wanted to be praised in classroom. Forty percent wanted to be praised often, 51% wanted to be praised sometimes, and only 9% never wanted to be praised. Interestingly, 84% wanted to be praised for trying hard and effort, while only 16% wanted to be praised for their ability and being smart. Most of students (52%) wanted to be praised quietly, while 31% wanted to be praised loudly in front of the class, leaving 17% who did not want to be praised publicly or quietly.

Developmental differences across the grades were noted. The need for praise increased from grade 3 to 5 and then declined over the next two grades levels. Students in grades 3 and 7 wanted to be praised at similar levels with the intermediate grades reporting that they wished to be praised more frequently. The students wanting the highest amount of praise were those in grades 4 to 6, suggesting that this is a developmental phase where students seek recognition and reassurance from their teachers. There were also developmental differences across the grades for effort and ability feedback. As students progressed through the grades they reported wanting more effort feedback and less ability feedback. Grade 3 students reported that they wanted about the same level of both effort and ability feedback, while grade 7 students reported wanting more effort feedback and less ability feedback. This suggests that younger students prefer to hear that they are smart and capable, but once this information is integrated into their self-concept they prefer to have their achievements attributed to their efforts.

Elwell and Tiberio (1994) investigated 620 high school students' preferences for the use of praise in their classrooms. Students in grades 9 and 10 wanted to be praised less frequently and less publicly than their younger and older counterparts in grades 7 and 8 and grades 11 and 12 respectively. The students in this study perceived the use of praise in the classroom as appropriate and expected to receive it for academic-related behaviors but not for socially appropriate behaviors. Nearly 60% of the students surveyed preferred quiet and private praise or no praise at all for academic success, while 41%

wanted to be praised loudly and publicly for their achievements. Elwell and Tiberio noted that students respond differently to praise, and teachers need to know about when, where, and under what circumstances praise should be delivered in the classroom.

USING PRAISE IN THE CLASSROOM

The research findings on the use of praise and feedback in the classroom have been integrated into guidelines for teachers. Burnett (2003) described a summary of what has been learned about praise and feedback in the classroom as a result of research.

Positive statements. Positive statements by teachers have a powerful impact and should be used in the classroom. Positive statements must be related to a behavior or performance. General praise that is not targeted or related to a specific behavior or performance has little impact on students and is not related to students' perceptions of the classroom environment or relationship with teacher. Thomas's 1991 descriptive reinforcement model (that is, name the student, use positive statements, describe the behavior) has merit.

Individual feedback. Praise and feedback should mostly be given individually. Only 31% of elementary students and 24% of high school students reported having a preference for public praise. Teachers should monitor a student's reaction to feedback as nearly one in five students reported not wanting to be praised at all, but this preference depends on circumstances and the student's grade level. Students should be praised for both effort and ability where warranted and appropriate for the grade level. Both types of feedback can be used despite having advantages and limitations.

Importance of grade level. The grade of the student is important. Students in grades 4 to 6 like to be praised more frequently and more publicly than students in grades 3 and 7, while students in grades 9 and 10 have a lower need for praise when compared with their older and younger high school peers. In the elementary school classroom students' preference for receiving effort feedback increases with grade, while preference for receiving ability feedback declines with grade.

PRESSLEY, G. MICHAEL 1951–2006

On May 23, 2006, the academic community lost one of its most brilliant and influential scholars in the fields of psychology and education. Michael Pressley, esteemed researcher and academic, died from complications associated with his fourth battle with cancer.

During his career, Pressley published more than 350 articles and book chapters and edited more than 25 books on psychology, literacy, and education. He especially was recognized for his senior authorship of the McGraw-Hill/SRA Open Course K-6 literacy program (also known as Open Court). He served as editor and board member for many prominent journals including *Journal of Educational Psychology* and the *Journal of Reading Behaviour*.

Pressley's dedication as a researcher was matched by his commitment to junior scholars. Pressley served as an advisor and mentor to dozens of doctoral and master's students throughout the United States and Canada, involving them extensively in his research and publication activities. Pressley also held great passion for K-12 schooling and involved himself in teacher preparation programs and the daily functions of elementary classrooms across America.

Pressley's schooling experiences, in part, shaped his interests in the psychology of learning. A student in the post-Sputnik era, Pressley participated in a science-enriched curriculum that concluded in his senior year with an 8-week research psychology summer session at Western Michigan University. This experience was profound in that it provided him with foundational insights about the enormous potential of research psychology to inform the field of education—insights that would subsequently be transformed into a professional passion.

Pressley completed his undergraduate studies at Northwestern University and earned a doctoral degree from the Institute of Child Development at Minnesota, specializing in cognitive development. Over the course of his career Pressley held positions at nine esteemed institutions including the University of Maryland-College Park, State University of New York, and Michigan State University.

A vigorous scholar, his research interests ranged from explorations in basic memory development to reading instruction. Pressley's initial explorations were largely quantitative and deepened understanding of effective learning strategies and study techniques, as well as factors that affected the learning process (good strategy user model). Adopting a variety of qualitative and mixed-methods methodologies, Pressley extended his research attentions to transforming educational practice and defining the essence of exemplary classroom instruction. His later interests focused in the area of reading comprehension and in monitoring and shaping teacher-student interactions as they negotiated meaning from text. Whether in the laboratory or in the classroom, students' positive learning experiences formed the foundation of Pressley's research and quickly earned him recognition as one of the nation's foremost educational researchers.

Pressley was the recipient of several prestigious career awards honoring his outstanding overall contributions to the fields of psychology and education, as well as his specific contributions in reading research and remedial reading diagnosis and programming for students at risk for reading and writing failure. These honors include induction into the Reading Hall of Fame, the Oscar Causey Award from the National Reading Conference, the Sylvia Scriber Award from the American Educational Research Association, and the Thorndike Award from the American Psychological Association. Pressley was honored with the University Distinguished Professor Award from Michigan State University and recognized as one of the top 100 University of Minnesota Distinguished Alumni from the College of Education and Human Development.

Pressley's contributions to the social science and education fields were unprecedented, as was his commitment to the universities, programs, and individuals he

Primary Language Acquisition

served. His intellect and leadership were matched by his compassion and unselfishness. Pressley was an individual who truly made a difference in the lives of his students and colleagues and his legacy remains with those who serve in America's classrooms.

PROBLEM-BASED LEARNING

SEE *Constructivism: Problem-Based Learning*.

PROBLEM SOLVING

A major goal of education is to help students learn in ways that enable them to use what they have learned to solve problems in new situations. In short, problem solving is fundamental to education because educators are interested in improving students' ability to solve problems. This entry defines key terms, types of problems, and processes in problem solving and then examines theories of problem solving, ways of teaching for problem solving transfer, and ways of teaching of problem solving skill.

DEFINITIONS

What is a Problem? A problem exists when a problem solver has a goal but does not know how to accomplish it.

Specifically, a problem occurs when a situation is in a given state, a problem solver wants the situation to be in a goal state, and the problem solver is not aware of an obvious way to transform the situation from the given state to the goal state. In his classic monograph, *On Problem Solving*, the Gestalt psychologist Karl Duncker defined a problem as follows:

A problem arises when a living creature has a goal but does not know how this goal is to be reached. Whenever one cannot go from the given situation to the desired situation simply by action, then there has to be recourse to thinking. Such thinking has the task of devising some action, which may mediate between the existing and desired situations. (1945, p. 1)

This definition includes high-level academic tasks for a typical middle school student such as writing a convincing essay, solving an unfamiliar algebra word problem, or figuring out how an electric motor works, but does not include low-level academic tasks such as pronouncing the sound of the printed word "cat," stating the answer to " $2 + 2 =$," or changing a word from singular to plural form.

What is Problem Solving? According to Mayer and Wittrock, problem solving is "cognitive processing directed at achieving a goal when no solution method is obvious to the problem solver" (2006, p. 287). This definition consists of four parts: (1) problem solving is cognitive, that is, problem solving occurs within the problem solver's cognitive system and can only be inferred from the problem solver's behavior, (2) problem solving is a process, that is, problem solving involves applying cognitive processes to cognitive representations in the problem solver's cognitive system, (3) problem solving is directed, that is, problem solving is guided by the problem solver's goals, and (4) problem solving is personal, that is, problem solving depends on the knowledge and skill of the problem solver. In sum, problem solving is cognitive processing directed at transforming a problem from the given state to the goal state when the problem solver is not immediately aware of a solution method. For example, problem solving occurs when a high school student writes a convincing essay on the causes of the American Civil War, understands how the heart works from reading a biology textbook, or solves a complex arithmetic word problem.

PROBLEM SOLVING AS A KIND OF THINKING

Problem solving is related to other terms such as thinking, reasoning, decision making, critical thinking, and creative thinking. Thinking refers to a problem solver's cognitive processing, but it includes both directed thinking (which is

problem solving) and undirected thinking (such as day-dreaming). Thus, thinking is a broader term that includes problem solving as a subset of thinking (i.e., a kind of thinking, i.e., directed thinking).

Reasoning, decision making, critical thinking, and creative thinking are subsets of problem solving, that is, kinds of problem solving. Reasoning refers to problem solving with a specific task in which the goal is to draw a conclusion from premises using logical rules based on deduction or induction. For example, if students know that all four-sided figures are quadrilaterals and that all squares have four sides, then by using deduction they can conclude that all squares are quadrilaterals. If they are given the sequence 2 4 6 8, then by induction they can conclude that the next number should be 10. Decision making refers to problem solving with a specific task in which the goal is to choose one of two or more alternatives based on some criteria. For example, a decision making task is to decide whether someone would rather have \$100 for sure or a 1% chance of getting \$100,000. Thus, both reasoning and decision-making are kinds of problem solving that are characterized by specific kinds of tasks.

Finally, creative thinking and critical thinking refer to specific aspects of problem solving, respectively. Creative thinking involves generating alternatives that meet some criteria, such as listing all the possible uses for a brick, whereas critical thinking involves evaluating how well various alternatives meet some criteria, such as determining which are the best answers for the brick problem. For example, in scientific problem solving situations, creative thinking is involved in generating hypotheses and critical thinking is involved in testing them. Creative thinking and critical thinking can be involved in reasoning and decision making.

TYPES OF PROBLEMS

Problems can be well-defined or ill-defined. A well-defined problem has a clearly specified given state, a clearly specified goal state, and a clearly specified set of allowable operations. For example, "Solve for x : $2x + 11 = 33$ " is a well-defined problem because there is clear given state (i.e., $2x + 11 = 33$), a clear goal state (i.e., $x =$) and a clear set of operations (i.e., the rules of algebra and arithmetic). An ill-defined problem lacks a clearly specified given state, goal state, and/or set of allowable operators. For example, "develop a research plan for a senior honors thesis" is an ill-defined problem for most students because the goal state is not clear (e.g., the requirements for the plan) and the allowable operators are not clear (e.g., the places where students may find information). What makes a problem well-defined or ill-defined depends on the characteristics of the problem. Although most important

and challenging problems in life are ill-defined, most problem solving in schools involves well-defined problems.

Moreover, it is also customary to distinguish between routine and non-routine problems. When a problem solver knows how to go about solving a problem, the problem is routine. For example, two-column multiplication problems, such as $25 \times 12 =$, are routine for most high school students because they know the procedure. When a problem solver does not initially know how to go about solving a problem, the problem is non-routine. For example, the following problem is non-routine for most high-school students: "If the area covered by water lilies in a lake doubles every 24 hours, and the entire lake is covered in 60 days, how long does it take to cover half the lake?" Robert Sternberg and Janet Davidson (1995) refer to this kind of problem as an *insight problem* because problem solvers need to invent a solution method (e.g., in this case the answer is 59 days). What makes problems either routine or non-routine depends on the knowledge of the problem solver because the same problem can be routine for one person and non-routine for another. Although the goal of education is to prepare students for solving non-routine problems, most of the problems that students are asked to solve in school are routine.

COGNITIVE PROCESSES IN PROBLEM SOLVING

Mayer and Wittrock (2006) distinguished among four major cognitive processes in problem solving: representing, in which the problem solver constructs a cognitive representation of the problem; planning, in which the problem solver devises a plan for solving the problem; executing, in which the problem solver carries out the plan; and self-regulating, in which the problem solver evaluates the effectiveness of cognitive processing during problem solving and adjusts accordingly. During representing, the problem solver seeks to understand the problem, including the given state, goal state, and allowable operators, and the problem solver may build a situation model that is, a concrete representation of the situation being described in the problem. Although solution execution is often emphasized in mathematics textbooks and in mathematics classrooms, successful mathematical problem solving also depends on representing, planning, and self-regulating. In a 2001 review, Jeremy Kilpatrick, Jane Swafford, and Bradford Findell concluded that mathematical proficiency depends on intertwining of procedural fluency (for executing) with conceptual understanding (for representing), strategic competence (for planning), adaptive reasoning, and productive disposition (for self-regulating).

According to Mayer and Wittrock (2006), students need to have five kinds of knowledge in order to be successful problem solvers:

facts: knowledge about characteristics of elements or events, such as “there are 100 cents in a dollar”;

concepts: knowledge of a categories, principles, or models, such as knowing what place value means in arithmetic or how hot air rises in science;

strategies: knowledge of general methods, such as how to break a problem into parts or how to find a related problem;

procedures: knowledge of specific procedures, such as how to carry out long division or how to change words from singular to plural form; and

beliefs: cognitions about one’s problem-solving competence (such as “I am not good in math”) or about the nature of problem solving (e.g., “If someone can’t solve a problem right away, the person never will be able to solve it”).

Facts and concepts are useful for representing a problem, strategies are needed for planning a solution, procedures are needed for carrying out the plan, and beliefs can influence the process of self-regulating.

THEORIES OF PROBLEM SOLVING

Many current views of problem solving, such as described in Keith Holyoak and Robert Morrison’s *Cambridge Handbook of Thinking and Reasoning* (2005) or Marsha Lovett’s 2002 review of research on problem solving, have their roots in Gestalt theory or information processing theory.

Gestalt Theory. The Gestalt theory of problem solving, described by Karl Duncker (1945) and Max Wertheimer (1959), holds that problem solving occurs with a flash of insight. Richard Mayer (1995) noted that insight occurs when a problem solver moves from a state of not knowing how to solve a problem to knowing how to solve a problem. During insight, problem solvers devise a way of representing the problem that enables solution. Gestalt psychologists offered several ways of conceptualizing what happens during insight: insight involves building a schema in which all the parts fit together, insight involves suddenly reorganizing the visual information so it fits together to solve the problem, insight involves restating a problem’s givens or problem goal in a new way that makes the problem easier to solve, insight involves removing mental blocks, and insight involves finding a problem analog (i.e., a similar problem that the problem solver already knows how to solve). Gestalt theory

informs educational programs aimed at teaching students how to represent problems.

Information Processing Theory. The information processing theory of problem solving, as described by Allen Newell and Herbert Simon (1972), is based on a human-computer metaphor in which problem solving involves carrying out a series of mental computations on mental representations. The key components in the theory are as follows: the idea that a problem can be represented as a problem space a representation of the initial state, goal state, and all possible intervening states and search heuristics a strategy for moving through the problem space from one state of the problem to the next. The problem begins in the given state, the problem solver applies an operator that generates a new state, and so on until the goal state is reached. For example, a common search heuristic is means-ends analysis, in which the problem solver seeks to apply an operator that will satisfy the problem-solver’s current goal; if there is a constraint that blocks the application of the operator, then a goal is set to remove the constraint, and so on. Information processing theory informs educational programs aimed at teaching strategies for solving problems.

TEACHING FOR PROBLEM SOLVING

Max Wertheimer (1959) made the classic distinction between learning by rote and learning by understanding. For example, in teaching students how to compute the area of a parallelogram by a rote method, students are shown how to measure the height, how to measure the base, and how to multiply height times base using the formula, $\text{area} = \text{height} \times \text{base}$. According to Wertheimer, this rote method of instruction leads to good performance on retention tests (i.e., solving similar problems) and poor performance on transfer tests (i.e., solving new problems). In contrast, learning by understanding involves helping students see that if they can cut off the triangle from one end of the parallelogram and place it on the other side to form a rectangle; then, they can put 1×1 squares over the surface of the rectangle to determine how many squares form the area. According to Wertheimer, this meaningful method of instruction leads to good retention and good transfer performance. Wertheimer claimed that rote instruction creates reproductive thinking applying already learned procedures to a problem whereas meaningful instruction leads to productive thinking adapting what was learned to new kinds of problems.

Mayer and Wittrock (2006) identified instructional methods that are intended to promote meaningful learning, such as providing advance organizers that prime appropriate prior knowledge during learning, asking learners to

explain aloud a text they are reading, presenting worked out examples along with commentary, or providing hints and guidance as students work on an example problem. A major goal of meaningful methods of instruction is to promote problem-solving transfer, that is, the ability to use what was learned in new situations. Wittrock (1974) referred to meaningful learning as a generative process because it requires active cognitive processing during learning.

TEACHING OF PROBLEM SOLVING

In the previous section, instructional methods were examined that are intended to promote problem-solving transfer. However, a more direct approach is to teach people the knowledge and skills they need to be better problem solvers. Mayer (2008) identified four issues that are involved in designing a problem-solving course.

What to Teach. Should problem-solving courses attempt to teach problem solving as a single, monolithic skill (e.g., a mental muscle that needs to be strengthened) or as a collection of smaller, component skills? Although conventional wisdom is that problem solving involves a single skill, research in cognitive science suggests that problem solving ability is a collection of small component skills.

How to Teach. Should problem-solving courses focus on the product of problem solving (i.e., getting the right answer) or the process of problem solving (i.e., figuring out how to solve the problem)? While it makes sense that students need practice in getting the right answer (i.e., the product of problem solving), research in cognitive science suggests that students benefit from training in describing and evaluating the methods used to solve problems (i.e., the process of problem solving). For example, one technique that emphasizes the process of problem solving is modeling, in which teachers and students demonstrate their problem-solving methods.

Where to Teach. Should problem solving be taught as a general, stand-alone course or within specific domains (such as problem solving in history, in science, in mathematics, ETC.)? Although conventional wisdom is that students should be taught general skills in stand-alone courses, there is sufficient cognitive science research to propose that it would be effective to teach problem solving within the context of specific subject domains.

When to Teach. Should problem solving be taught before or after students have mastered corresponding lower-levels? Although it seems to make sense that higher-order thinking skills should be taught only after lower-level skills have been mastered, there is sufficient

cognitive science research to propose that it would be effective to teach higher-order skills before lower-level skills are mastered.

In this section, three classic problem-solving courses are described that meet these four criteria and that have been subjected to rigorous research study: the Productive Thinking Program developed by Martin Covington, Richard Crutchfield, and Lillian Davies (1966), Instrumental Enrichment developed by Reuven Feuerstein (1980), and *Odyssey* described by Raymond Nickerson (1994). The Productive Thinking Program consisted of 15 cartoon-like booklets intended to teach thinking skills to elementary school children. Each booklet presented a detective-type story such a story about a bank robbery and students learned how to generate hypotheses such as who might have done it and evaluate hypotheses using information in the booklet. Child characters in the booklet modeled problem-solving methods, and adult characters offered commentary and hints. Overall, Richard Mansfield, Thomas Busse, and Ernest Krepelka (1978) reported that students who learned with the Productive Thinking Program showed greater improvements in their ability to solve similar detective-type problems as compared to students who had not received the training.

In Instrumental Enrichment, students who had been identified as mentally retarded based on a traditional intelligence test were given concentrated classroom instruction in how to solve traditional intelligence test items. In a typical lesson, the teacher introduces the class to an intelligence test item; then, the class breaks down into small groups to devise ways to solve the problem; next, each group reports on its solution method to the whole class; and finally, a teacher-led discussion ensues in which students focus on describing effective methods for solving the problem. Evaluation studies reported by Feuerstein (1980) show that students who received this training on a regular basis over several years showed greater gains in non-verbal intelligence than did non-trained students.

Finally, in *Odyssey*, middle-school students received training in how to solve intelligence test problems, using a procedure somewhat like Instrumental Enrichment, and with similar results. David Perkins and Tina Grotzer reported that the training “enhanced the magnitude of students’ intelligent behavior [on] authentic tasks at least in the short term” (2000, p. 496). Overall, each of these courses met the criteria for what to teach (i.e., a collection of small component skills), how to teach (i.e., using modeling to focus on the process of problem solving), where to teach (i.e., teaching specific skills), and when to

Project-Based Learning

teach (i.e., teaching before all lower-level skills were mastered). Although none of these programs is currently popular, courses based on these four criteria are likely to be successful.

PROJECT-BASED LEARNING

SEE *Constructivism: Project-Based Learning.*

PROSOCIAL BEHAVIOR

Prosocial behaviors are voluntary behaviors made with the intention of benefiting others (Eisenberg & Fabes, 1998). This definition carefully circumvents the potential benefits to the person performing the prosocial behavior. Prosocial behavior is often accompanied with psychological and social rewards for its performer. In the long run, individuals can benefit from living in a society where prosociality is common (which, in evolutionary terms, increases reproductive potential). It has therefore been difficult for researchers to identify purely altruistic behaviors, benefiting only the recipient and not the performer. Nevertheless, behaviors benefiting others, but whose main goal is self-advantageous (e.g. cooperative behaviors intended to obtain a common resource), typically are not considered prosocial. Typical examples include: volunteering; sharing toys, treats, or food with friends; instrumental help (e.g., helping a peer with school assignments); costly help (e.g. risking one's own life to save others); and emotionally supporting others in distress (e.g., comforting a peer following a disappointing experience or caring for a person who is ill).

DEVELOPMENTAL CHANGES

Prosocial behavior has roots in human evolutionary history as de Waal's comparison with other species shows. Nevertheless, Fehr and Fischbacher note that humans are unique in their degree of prosociality. Hoffman's theory proposes that prosocial behavior becomes increasingly other-oriented as children mature. Infants feel self-distress in reaction to the distress of others because they are incapable of differentiating their own experiences from those of others. Gradually, self-distress is replaced by other-oriented concern, requiring some understanding of others' mental states (Hoffman, 2000). Zahn-Waxler, Robinson, and Emde show that by age 4, many children can react empathically to others, including offering help to those in distress.

The 1998 Eisenberg and Fabes meta-analysis found that prosocial behavior increases with age, although increases varied in size, depending on the methodological aspects of each study. In one study by Benenson, Pascoe, and Radmore, about 60 percent of 4-year old children donated at least one of 10 stickers they received to a peer, and about 85 percent did so at age 9. This increase was markedly elevated for higher-SES children compared to lower-SES children. From childhood to adolescence

further increases are found in sharing, but not in helping or providing emotional support (Eisenberg & Fabes, 1998). The boost in prosocial behavior with age is attributed to developmental increases in cognitive abilities associated with detecting others' needs and determining ways to help, in empathy-related responding, and in the moral understanding of the importance of helping others (Eisenberg et al., 2006).

CONTEXTUAL AND INDIVIDUAL INFLUENCES

Many contextual factors are associated with prosocial behavior. For example, Cole and colleagues report short-term success for television programs designed to increase children's prosociality. Social psychological experiments consistently show that recognizing a situation as requiring assistance, involving personal responsibility, and enabling oneself to help, all increase helping behavior (Penner, Dovidio, Piliavin, & Schroeder, 2005). Individuals are more likely to provide support in situations that promote personal psychological and material rewards, or where the costs (e.g., guilt) associated with not helping are prominent. Finally, individuals are more likely to behave prosocially towards similar or likable others (Penner et al., 2005), and towards others considered to be close, especially kin (Graziano et al., 2007). This pattern may reflect an ultimate evolutionary goal of kin selection as described by Hamilton, although de Waal notes that helpers' psychological goals may be quite different. Genetic relatedness aside, prosocial behavior towards family members probably involves a sense of duty, reciprocity, and affective relationships.

Rushton describes moderate consistency in individuals' prosocial behavior across varying situations and contexts, demonstrating both stable individual differences in prosociality and the importance of contextual factors. Research following children from early childhood to adulthood supports the existence of the long-debated altruistic or prosocial personality (Eisenberg et al., 1999). Individual differences in prosociality are linked to sociability, low shyness, extroversion, and agreeableness, although specific prosocial behaviors may require a combination of additional traits, such as perceived self-efficacy in the case of helping (Penner et al., 2005). Researchers Bardi and Schwartz highlight the importance of individuals' specific prosocial values, including emphasizing the importance of the welfare of others, as an additional variable likely to influence prosocial behavior. Personality and contextual variables are likely to interact in determining prosocial behavior. For example, agreeable individuals were more likely to help an outgroup member than low-agreeableness

individuals, but agreeableness was not associated with helping an ingroup member (Graziano et al., 2007).

Environmental factors linked to individual differences in children's prosociality include parental modeling of helping behavior and use of inductive discipline (e.g., explaining to children the consequences of their behavior) as opposed to power-assertive discipline (e.g., punishment) (Eisenberg & Fabes, 1998). Beyond parental influence, siblings, peers, and schools also may affect prosociality. For example, as Wentzel, McNamara, and Caldwell point out, children's prosociality may be influenced by close friends. Furthermore, the better the affective quality of the friendship, the more influential friends are to each other's prosociality.

Genetics also contribute to individual variation in prosociality. Research on adults finds that prosociality is substantially heritable. Research on young children shows lower heritability, demonstrated by one longitudinal twin study showing increases in the heritability of parent-rated prosociality, from 30 percent at age 2 to 60 percent at age 7 (Knafo & Plomin, 2006).

Genetic and environmental effects are often intertwined. For example, parental reasoning may be more effective with highly attentive children, while external rewards may work better for other children. These gene-environment interactions, in which children's genetically influenced tendencies interact with environmental influences in determining behavior, are highly likely. Further investigation is necessary of gene-environment interactions with regard to prosociality. Gene-environment correlations can also shape individual differences in prosociality. For example, children's low prosociality is related to parents' use of negative discipline and affection. This relationship can be traced back to children's genetic tendencies, implying that the genetically influenced low prosociality can initiate a negative reaction from parents (Knafo & Plomin, 2006).

Gender and culture are additional predictors of prosocial behavior. A meta-analysis found small differences favoring girls in prosocial behavior, smaller than expected based on gender stereotypes and lower for instrumental help than for other prosocial behaviors (Eisenberg & Fabes, 1998). Some evidence suggests that children in Western societies are less prosocial than children in other cultures, but some studies find no differences along these lines (see review by Eisenberg et al., 2006). A field study by Levine, Norenzayan, and Philbrick found large cultural differences in spontaneously helping strangers. For example, the proportion of individuals helping a stranger with a hurt leg pick up dropped magazines ranged from 22 percent to 95 percent across 23 cultures. Although national wealth was negatively associated with helping rates, the closely related cultural value of

individualism-collectivism (individualism is on average higher in richer countries) was not related. A compelling cultural explanation for cross-national differences in prosocial behavior was still needed as of 2008. Perhaps, cultures differ substantially in what each promotes as prosocial behavior (Eisenberg et al., 2006).

RELATION TO OTHER ASPECTS OF SCHOOL FUNCTIONING

Clark and Ladd find that prosocial children are relatively well adjusted and have better peer relationships than less prosocial children. Highly prosocial children have more friends and report a better quality of friendship, relative to less prosocial children.

Caprara and colleagues find positive relationships between children's early prosocial behavior and later academic achievement, and positive peer relations (statistically controlling for earlier achievement). The exact nature of these relationships has yet to be determined. Possibly, prosocial children's superior social skills enable them to work better with peers and to get along better with teachers. Alternatively, earlier prosociality represents self-regulation abilities needed for later achievement. Similarly, a finding by Johnson and colleagues that volunteering adolescents have higher grade point averages and intrinsic motivation toward schoolwork may indicate that volunteering increases academic self-esteem. Furthermore, adolescents who volunteer may receive preferential treatment from teachers, increasing their achievement.

HOW TEACHERS AND SCHOOLS CAN PROMOTE PROSOCIAL BEHAVIOR

Although observational studies suggest that preschool teachers usually do little to encourage prosocial behavior, teachers' behavior and school policies can promote prosociality. Positive, warm, and secure teacher-student relationships are associated with children's prosociality (Eisenberg et al., 2006).

To overrule the possibility that highly adjusted children are both prosocial and elicit positive reactions from teachers, intervention studies are essential. A five-year longitudinal study by Solomon and colleagues finds that training teachers to promote children's prosociality and developmental discipline increases children's prosocial values and behaviors. The program provided children with an opportunity to work collaboratively in small groups and participate in activities designed to promote social understanding. It emphasized prosocial values through the use of relevant media and highlighting children's positive behaviors and provided opportunities for active helping such as a buddy program that assigned older children to help younger peers.

In another school intervention reported by Fraser and colleagues, children received training designed to teach social problem-solving skills and to reduce peer rejection. Simultaneously, parents participated in home lessons designed to improve parenting skills (e.g., child development, parent-child communication, problem-solving, and discipline). Intervention children increased in prosocial behavior in comparison to the control group. Another experimental school program reported by Flannery and colleagues shows longitudinal gains in children's prosocial behavior by altering school climate by teaching students and staff five simple rules and activities: (a) praise people, (b) avoid put-downs, (c) seek wise people as advisers and friends, (d) notice and correct hurts one causes, and (e) right wrongs.

McMahon and Washburn point out that effective interventions often work to address students' empathy and problem-solving skills and are often tailored to the cultural, developmental, and behavioral characteristics of students. Research by Kazdin, Bass, Siegel, and Thomas reveals the effectiveness of cognitive-behavioral therapy in increasing prosociality in children with severe antisocial behavior. Another violence prevention program reported by DeCarlo and Hockman improves male urban African American students' prosocial skills through analysis of relevant RAP music lyrics. Furthermore, Lakes and Hoyt show the effectiveness of tae-kwon-do training at primary school to improve self-regulation and prosocial behavior among boys and, to a lesser extent, girls. Attention/play interventions by school psychologists with highly aggressive boys (modeling, role-playing, coaching, feedback, and discussion of play strategies), by Dubow and colleagues longitudinally decrease aggression and increase prosocial behavior. These studies demonstrate the usefulness of non-preaching approaches to prosocial development.

PROVIDING EXPLANATIONS

Written explanations in classrooms have the goal of teaching a new understanding to students. According to genre theory, writers build a set of characteristics into explanations that readers use to learn from their reading. Cognitive load theory and educational psychology specify how the set of characteristics in an explanation could be designed to teach new domain understandings to students who do not yet have expertise. A synthesis of these separate areas of scholarship suggests guidelines for providing explanations that effectively teach important content to particular students.

EXPLANATION AS A GENRE

Genre theory specifies the characteristics of different genres and proposes a mechanism for how genres have developed. According to the theory, the identifiable patterns of structure and content that characterize any genre result from the work of communities of people completing recurring tasks and fulfilling shared purposes. A writer with a particular purpose in mind composes a text

with content, structure, and style characteristics that a prospective audience also knows and can use to fulfill a purpose, which may or may not match the goal intended by the author. The author who would write an explanation chooses characteristics with the purpose of communicating a new understanding to potential readers. Well-designed explanations present information, examples, analogies, diagrams, pictures, and models as subexplanations. These subexplanations follow a logical order to form a bridge between readers' current understandings and the new understanding. The goal for the reader is to construct a new understanding by attending to the subexplanations and following the text's logical order.

For example, the British physicist and astronomer, Sir James Jeans (1877–1946), wrote a short explanation titled “Why the Sky Is Blue” based on a series of radio talks for an audience with no formal knowledge of science. Jeans began by asking the reader to imagine standing on an ocean pier watching the waves roll in and strike the columns supporting the pier. This first subexplanation contrasted what happened to short and long ocean waves with the purpose of reminding the reader of an experience that the reader could readily imagine. The second subexplanation chronicled the movement of light waves through the atmosphere, a series of events that cannot be directly perceived. The third subexplanation mapped the model of water waves onto the model of light. The explanation ended with an explicit description of light waves moving through the atmosphere and ended with the two short sentences, “Consequently the blue waves of the sunlight enter our eyes from all directions. And that is why the sky looks blue.” This explanation presents four subexplanations logically ordered to juxtapose a readily perceivable and imaginable phenomenon that readers may have actually seen with a scientific model to bridge the knowledge of a novice and the understanding of an expert.

Explanations with these features appear in science textbooks in the United States, in science and social studies textbooks internationally, in science and social studies trade books, and in magazine articles and books written for the general public. They also appear in composition books prepared to teach important genres to novice writers (e.g. the anthology that includes Jeans's explanation). The educational community seems to have developed this genre to help learners gain new understanding.

COGNITIVE LOAD THEORY

Whereas rhetoricians have proposed a theory to explain the characteristics and development of genres, Cognitive load theory, developed by cognitive psychologists, explains how learning occurs and suggests constraints on the design of successful explanations. According to

the theory, the mind is composed of a limited working memory through which information enters the mind and a limitless long-term memory, which stores information that has successfully been processed in working memory as organized schemas. The schemas are abstract structures that store large amounts of information. Working memory can hold only a small number of discrete “bits” of information, and thus can be something of a bottleneck. Learning cannot occur if incoming information overloads working memory capacity; if the cognitive load is too great. But a schema is processed as a single bit. Schemas effectively reduce cognitive load.

Cognitive load can be intrinsic, germane, or extraneous. Intrinsic cognitive load depends on the complexity of the information and whether the learner already has at least one relevant schema. If intrinsic load is not too great, the learner may have the capacity in working memory to engage in processes that are germane to learning, including constructing new schemas. Instruction is effective to the extent that it enhances germane cognitive load. In contrast, instruction may actually impede schema acquisition by enhancing extraneous cognitive load, such as requiring readers to search for or organize information within instructional materials rather than presenting information coherently.

Cognitive load theory provides a framework for understanding how well-designed explanations enhance learning. Psychologically, domain understandings, such as understandings about light developed by physicists, are stored in long-term memory as schemas. The purpose of classroom explanation is to reduce intrinsic and extrinsic cognitive load so that the reader has the working memory capacity to construct a new schema. The design of the subexplanations and how they are ordered must meet this goal in order for learning to occur.

REDUCING INTRINSIC COGNITIVE LOAD

Originally the theory specified that instruction could not modify intrinsic cognitive load. However, research by psychologists John Sweller and Richard Catrambone and others using explanations of chemistry models and written mathematics tasks suggests that presenting instruction as a series of simplified tasks can reduce intrinsic cognitive load. Young adolescent boys following instructions to build molecular models completed the tasks more quickly for 10 simple models with only two related elements each than for 2 complex models with several related elements. Other work using written mathematics tasks suggests that presenting instruction as a series of simplified versions of a complex task can reduce intrinsic cognitive load. Intrinsic cognitive load can be reduced by restricting the number of related elements

that the learner must consider at a single point in time. Choosing incoming information that matches a known schema also reduces intrinsic cognitive load. The adolescents were faster for the complex models if the instructions were diagrammatic rather than text, matching the structure of a common graphic organizer used in school. Apparently, they had a schema that they could use to reduce the intrinsic cognitive load for even complex models. “Why the Sky Is Blue” offers an example of this process. It presents a sequence of subexplanations, each of which has a smaller number of related elements than is true for the explanation as a whole. It also begins with the ocean wave example, for which readers may well have a schema. Both of these features could reduce intrinsic load and thereby allow readers to understand the subexplanations about light waves.

REDUCING EXTRANEOUS COGNITIVE LOAD

In an explanation, any example, diagram, information, analogy and so on that does not relate directly to the schema to be acquired would increase extraneous cognitive load. Eliminating unnecessary input would reduce cognitive load and facilitate comprehension. For example, research by psychologist Richard Mayer and others has shown that learners reading a text with only a qualitative description of a model of ocean waves learned more than learners reading a text with quantitative data interspersed within the qualitative description. In the “Why the Sky Is Blue” example, this criterion is met, as each subexplanation relates to the light wave schema.

Texts that require the reader to expend working memory resources figuring out how to process the input also increase extraneous cognitive load. Designing a text to minimize processing unrelated to schema acquisition reduces this load. Research has shown that learners reading a text with captions that point out the relevant features in a diagram or highlighting that signals important relations in a text learn more than learners reading texts without these features. Reducing extraneous cognitive load is particularly important if intrinsic cognitive load is high. Reading diagrams that depicted the relations among chemical elements facilitated how quickly adolescents constructed complex models over reading prose explanations. Prose explanations would not directly represent the relations among elements in the model and might well require learners to create in working memory their own images, adding to the overall cognitive load.

Local coherence also reduces extraneous cognitive load. Readers reading texts with clear pronoun referents, paragraphs organized around a single idea, and paragraph topic sentences learn more than readers reading texts without local coherence, who must dedicate working

memory capacity to creating the local coherence themselves. Topic sentences from “Why the Sky Is Blue” such as, “We have been watching a sort of working model of the way in which sunlight struggles through the earth’s atmosphere”; (p. 703) and “The waves of the sea represent the sunlight” (p. 704), draw the reader’s attention to important relations in the text and also could help readers connect the subexplanations, therefore decreasing extraneous cognitive load.

Eliminating redundancy can decrease cognitive load as well. If an explanation only has content that relates to the expert schema, provides enough support so that the learner does not have to figure out how to process the input, and is coherent, adding additional explanatory support is redundant. Processing this redundancy increases extraneous cognitive load. Learners who read more concise explanations without additional, less central explanatory content learned more than learners who read elaborated versions with additional explanatory content. Redundancy only exists when an explanation has been designed well enough to lead to schema acquisition without the additional content. “Why the Sky Is Blue” is short, and it is likely that this explanation would have redundant content only for readers who already have the light wave schema.

ENHANCING GERMANE COGNITIVE LOAD

Germane cognitive load results from input that can stimulate the higher cognitive processes necessary for schema acquisition. The same features that decrease intrinsic and extrinsic cognitive load can also contribute to germane cognitive load if they enhance schema acquisition. For example, if all subexplanations are related to the schema, readers have the input to compare and contrast the subexplanations, abstract general similarities, and construct a schema that incorporates the separate subexplanations. If the explanation signals the similarities explicitly through captions on diagrams, explicitly noting the relationships between analogs, or worked out mathematical examples, readers’ attention will be further directed away from extraneous content and toward the similarities.

Research has suggested that providing subexplanations with different surface features can encourage learners to abstract the general similarities and construct a schema. The subexplanations in “Why the Sky Is Blue” present an analogy, the light wave model, a mapping of the analogy onto the model, and the sequence that results in the perception of the color blue. These multiple subexplanations could be expected to enhance germane cognitive load and learning because they all exemplify the underlying relationships in the schema and are not so numerous as to become redundant. Learners would be

thus more likely to focus cognitive effort on the relevant parts of the subexplanations.

The order in which an explanation presents subexplanations can also enhance germane cognitive load. Research on the development of expertise suggests that novices begin with simple schemas, and through practice, construct progressively more complex and useful schemas that ultimately are so well known that they are automatic and bypass working memory altogether. An explanation that begins with a simple, known schema followed by subexplanations that present progressively more complex schemas, could provide the input that a novice would be able to use to construct an expert schema. The subexplanations for “Why the Sky Is Blue” follow this simple to complex order.

EXPLANATIONS TO PROMOTE DOMAIN LEARNING

The challenge in providing explanations to promote domain learning is that typically students either lack obvious schemas upon which to construct new understanding or the schemas that they do have are misleading and interfere with domain learning. First, learners may lack schemas for letter-sound correspondences and grammatical patterns in English. Consequently, they may require so much working memory capacity to process the symbols on the page that no capacity is left for schema construction. Second, students may not have a schema for the generic characteristics of explanation and therefore be unable to take advantage of the subexplanations and logical order in the text. Rather than processing the text as a single unit in working memory, they may instead be overwhelmed by the individual pieces of information in the explanation. Third, students may either have no schemas for the content in the text, or the schemas that they do have may be based on everyday experiences that interfere with their construction of counterintuitive domain-based understandings. Naïve understandings most obviously interfere with new understandings in science, but they can also occur for formalistic vocabulary in mathematics and stereotypes in social studies and English.

LACKING DECODING SCHEMAS

Students who lack letter-sound and sentence grammar schemas struggle with almost all reading tasks. Because their struggles to decode and maintain fluency take up so much working memory capacity, it is of utmost importance that intrinsic load be minimal and other types of extrinsic load be eliminated. Intrinsic load can be minimized by providing explanations that rely heavily on pictures and familiar types of diagrams accompanied by a limited amount of text. Presenting the content in diagrams and pictures will eliminate the need for large

amounts of decoding; accompanying these features with a limited amount of text will give the readers practice in decoding successfully and thereby constructing the decoding schemas that they are lacking. “Why the Sky Is Blue” has no features that would support readers who lack decoding schemas. It was written for adults who presumably have these schemas.

Firmly established content schemas can also minimize intrinsic cognitive load. Students who struggle to decode otherwise can at times read content about which they have well-established schemas quite fluently. The problem, of course, is that the purpose of explanations is to lead to new understanding. The optimal balance between known and new for readers who struggle to decode is an important area for future research.

LACKING TEXT SCHEMAS

Explanations can be designed to build on text schemas that students typically have and compensate for text schemas that they lack. The most firmly established text schema for most students is narrative. Educational psychologists Linda Kucan and Isabel Beck, for example, have demonstrated that fourth graders seem to be able to follow the logic in narratives and fail to follow the logic in expositions. Asked to recall after reading, children up through fifth grade and beyond tend to recall the gist of stories and unconnected bits and pieces of expository texts what educational psychologist Bonnie Meyer has called the default list. Overall, explanation is exposition. It is structured as a series of subexplanations, not as a plot with characters. It might be expected that many students would lack a schema for explanation. However, subexplanations within explanations can be narrative. “Why the Sky Is Blue” starts with a narrative-like example with the reader as the main character, the waves and the pier as the setting, and what happens to the waves as the plot. It is possible that readers could use a narrative schema to process the remaining subexplanations even though the explanation as a whole is exposition.

Readers lacking a text schema can begin to construct one through signaling. Across a number of studies, research has demonstrated that introductions that synopsize the text structure; paragraph topic sentences and words such as “first,” “then,” and “however” that signal the structure of the text; and conclusions that summarize direct a reader’s attention to the generic patterns in a text. Explanations with these features would prompt readers to process an explanation within working memory as a single unit rather than a succession of unrelated bits of information. “Why the Sky Is Blue” has no signals that would help readers process it as an explanation.

HAVING WELL ESTABLISHED NAÏVE UNDERSTANDINGS

A challenge in most scholarly domains is to help students use expert models to explain everyday experience. In economics, models of supply and demand can explain fluctuations in price. In history, models of limited resources can explain why one country would invade another. In science, scholars have proposed and demonstrated causal models that can be used to explain and predict a wide range of phenomena. These models reduce phenomena to a set of core theoretical ideas that are often very different from the realm of everyday knowing. Indeed, a challenge in all domains, but particularly science, is to help students use expert models to explain everyday phenomena. Unfortunately, the schemas that students have, rather than guiding their understanding, can actually interfere with their construction of a new schema. Often texts for use in classrooms begin with the target model to be taught and do not address students' naïve models, typically failing to prompt students to construct a new schema. "Why the Sky Is Blue" fits this pattern, in that it does not directly address students' prior ideas about light.

A type of explanation called *refutational text* has proven to be an effective way to help readers adopt scientific models that may even be at odds with their naïve experience-based schemas. Refutational texts begin with a subexplanation that presents the naïve model based on everyday experiences, and follow with subexplanations that are logically ordered to demonstrate the limitations of the naïve model, present the scientific model, and point out how it addresses the limitations. Students who demonstrated naïve understandings before reading were more likely to demonstrate expert understanding after reading refutational texts than other students who conducted experiments, discussed in small groups, or read typical textbook material that did not "refute" their naïve understandings.

IMPLICATIONS FOR TEACHERS

The most important implication for teachers is to choose and compose explanations carefully. The well-designed explanation begins with a schema that the teacher could expect students in the class to have. If the children's schema contrasts with the expert understanding, the explanation is designed as a refutational text. The effective explanation has no extraneous content and is locally coherent. Subexplanations are varied, including diagrams and pictures to highlight the relationships in the schema where appropriate, as well as narrative examples. The explanation is as explicit as possible, drawing connections among each successive subexplanation, highlighting important relationships and including informative dia-

gram captions. Subexplanations follow a logical order, from part to whole, from simple to complex, from familiar to unfamiliar. Knowing the students well, the teacher chooses or develops an explanation with the optimal relationship between known and new to maximize germane cognitive load and student learning.

Most explanations will not match this set of characteristics perfectly. For example, "Why the Sky Is Blue" does not include diagrams and pictures, nor does it address possible naïve understandings. For less than perfect explanations, classroom instruction would need to provide what the explanation lacks. Students could draw missing diagrams or write captions for diagrams that are in the text, brainstorm before reading to access relevant schemas, and create graphic representations of the ideas in the explanation to highlight relevant content. Students could process more than one explanation, each of which could make up for lacks in the other. Even though research suggests that reading print may lead to learning more effectively than watching or listening to other types of media, students who lack decoding or relevant content schemas can learn better from a combination of print and other media than either by itself.

QUALITATIVE RESEARCH

A doctoral student collecting data for her dissertation visits a third grade classroom where two children labeled autistic are regular members. She goes there several days per week staying approximately four hours each time. She tries to remain as unobtrusive as possible observing the natural class environment and activities as they occur. When she leaves each day she goes to her home computer and writes detailed notes of everything she has seen and heard. In addition, she keeps a diary of her personal reactions and evolving thoughts. After she has been there six weeks, she begins conducting recorded interviews with the teacher and other school staff. She even interviews some of the parents of children in the classroom. Rather than using a questionnaire she asks general questions, leaving room for the respondents to raise issues and to freely express themselves. In conjunction with this interview information she gathers various official documents, student evaluations, and other information related to the class.

This researcher is interested in social relationships and learning in the room especially the experiences of the children labeled disabled. She wants to understand the classroom both from the teacher's point of view and that of other people involved. Although these are her general interests she did not state specific hypotheses or questions before she started. When she finishes the data collection she reads, rereads, and codes her descriptive data. She relies on one of the computer software programs available to help organize and analyze her qualitative data. Then she writes a dissertation about what she has learned.

DEFINITION OF QUALITATIVE RESEARCH

The researcher is engaging in qualitative research in the classroom. Her comprehensive data collection approach is not the only one qualitative researchers use to study classrooms. Some rely solely on in-depth interviews, others limit their data collection to intense observation, others on first person document analysis. Other techniques exist as well but what those who practice qualitative research in education have in common are the following:

1. Their data is descriptive (e.g. field notes, interview transcripts).
2. Their analysis is inductive (the questions and focus are not predetermined but evolve as the data are collected).
3. Their data are typically collected in natural settings, in classrooms, and in other places teachers and students spend their time. They try to conduct interviews on location and in a conversational style.
4. Their data are not reduced to numbers and they do not employ advanced statistical procedures. During data analysis some qualitative researchers use frequency counts and other simple quantitative procedures, but, for the most part, their reports are descriptive and conceptual.
5. Their goal is to understand basic social processes (e.g. how children play and learn in a group) and in developing insights in the form of sensitizing concepts. In addition they try to grasp the view of the world from the point of view of the participants (the

teachers, students and others related to the classroom). Their concern is not with prediction and the relationship between discrete variables.

IS IT A QUALITATIVE STUDY?

The example of the doctoral student collecting data for her dissertation is an exemplar of qualitative research of classroom learning. Her study contains all of the elements of this kind of research. Not all studies that people refer to as qualitative research incorporate all of these characteristics however. For example, some researchers might start with stated questions, others may emphasize interviews with teachers thereby straying from observations in the classroom. Whether a particular study is called qualitative is a judgment regarding the degree it contains the above elements rather than whether it meets all the criteria. As discussed below, researchers have different ideas about where to draw the line. Thus some researchers call what they do qualitative research, whereas others would not.

Terms previously used and currently associated with this form of research include: fieldwork, naturalistic, ethnographic, symbolic interaction, inner perspective, Chicago School, phenomenological, case study, interpretive, ethnomethodological, ecological and descriptive. These terms are not synonymous with qualitative research. Rather qualitative research is an umbrella for them all. The exact definition of each varies within particular research traditions and from user to user and from time to time. But each refers to approaches with many of the elements that are part of qualitative research as defined above.

EARLY HISTORY

Researchers employing the general approach described above have existed since the systematic inquiry began. Academic anthropologists and sociologists have used it since the late 1890s. Typically the former conducted studies in cultures other than their own, in so-called less developed or unindustrialized societies. Sociologists did similar work in Western countries. Although the approach was widely employed, the term *qualitative research* was not coined until the late 1960s. In 1967 scholars Barney Glaser and Anselm Strauss first used the phrase in the title of a book, *The Discovery of Grounded Theory: Strategies for Qualitative Research*. William Filstead followed in 1970 with his edited collection, *Qualitative Methodology*. In the late 1960s and early 70s some researchers, including those in education, began a dialogue about the approach outside the academic boundaries of anthropology and sociology.

HISTORY OF QUALITATIVE RESEARCH IN EDUCATION

Two of the earliest researchers to apply qualitative approaches to education in the United States were Mar-

garet Mead and Willard Waller. In the 1940s Mead, an anthropologist, used her fieldwork in less technically developed societies to reflect on the rapidly changing education system in the United States. She examined how what she called little red schoolhouses, city schools, and academies required particular kinds of interaction between teacher and student. She advocated that teachers use first-hand observation to study changes in schools and pupils as a way for them to become better teachers.

When Willard Waller published his work in the 1930s sociology was dominated by quantitative approaches. His book *Sociology of Teaching* (1932) relied on various kinds of descriptive data to analyze the social world of teachers and their students. He saw schools as people tied together in a complex maze of social interconnections. His book was designed to help teachers develop insight into the social nature of school life as a way of facilitating learning in the classroom.

In 1951 Howard Becker, a sociologist who would become very influential in the development of qualitative approaches to research, wrote his dissertation on the careers of Chicago school teacher and social-class variation in teacher-pupil relations. He used qualitative interviews to collect his data. Becker went on to launch a series of qualitative research studies on various aspects of education and encouraged a number of graduate students to follow his lead.

COMING OF AGE

Few important qualitative studies in education appeared prior to the 1960s. Quantitative methods continued to dominate research about schools and classrooms. Change began in the sixties as qualitative research began finding a small but enthusiastic following. During this decade the nation began focusing on educational problems, especially de facto segregation and the underachievement of minority students in the classroom. Civil rights leaders and other concerned citizens demanded that people take into account what teaching and learning was actually like in the classroom. Popular journalistic accounts of school life and autobiographical writings by teachers which documented the lack of learning in ghetto schools grabbed the attention of the public. In 1968 Jonathan Kozol's *Death at an Early Age: The Destruction of the Hearts and Minds of Negro Children in the Boston Public Schools*, his poignant account of his first year of teaching in a ghetto school in Boston, won a National Book Award. People wanted to know more about what was actually going on in schools.

Educational researchers began practicing qualitative strategies themselves in the 1960s rather than depending upon sociologists and anthropologists. Federal agencies began to see the promise in this research approach and

started to fund qualitative research. A number of these studies addressed inequality in schools. In 1963 Project True at Hunter College in New York City relied on interviews to examine the experiences of new teachers in urban schools and school integration (Eddy, 1967; Fuchs, 1969). Other researchers recognized that education had failed poor children and that this chronic problem needed to be studied in new ways. Eleanor Leacock focused her influential inquiry on the effect of school authorities on student behavior and learning. Jules Henry studied racism in elementary schools in St. Louis. It was through this project that Ray Rist, an important practitioner of qualitative research, started his career. His book, *Urban School: Factory for Failure*, a systematic observational study of learning in one classroom, was widely read by policymakers and researchers alike.

EMERGENCE OF THE FIELD OF QUALITATIVE RESEARCH

The 1960s were both the launching period of qualitative studies and the time that qualitative research emerged as a field. Prior to the 1960s courses in qualitative research were uncommon. Instruction in the method was mainly in anthropology and sociology through apprenticeships with professors engaged in research projects. A well-developed literature on the theories underlying the method and how to do it had not developed. In the late 1960s and early 1970s such a literature began to emerge and courses began to be offered. In 1966 Severyn Bruyn published *The Human Perspective in Sociology*, a comprehensive theoretical methodological treatise on the qualitative tradition. His book was followed by Glaser and Strauss's *Discovery of Grounded Theory: Strategies for Qualitative Research*, which for the first time presented the logic behind qualitative analysis. In 1971 Rosalie Wax published one of the first qualitative methods books, *Doing Fieldwork: Warning and Advice*. The literature grew. The early 1970s also saw courses in the approach being offered for the first time. Additionally, a literature began appearing in education and in other professional schools that addressed the research dilemmas inherent in classrooms and in other places where human service professionals practiced their trade.

The 1970s and 1980s saw qualitative research flower in education. Not only did well established educational research journals start regularly publishing articles that employed qualitative research, but also new journals favoring the approach first appeared. Book publishers welcomed titles on qualitative research and special sessions at meetings of professional educational researchers were devoted to the subject. Organizations emphasizing the qualitative approach arose and conferences devoted

to the approach became regular features of educational researchers' calendars.

CONFLICT AND DEBATE

Not all educational researchers embraced qualitative research during the 1970s and 1980s, however. Some professors and other researchers who were trained in quantitative approaches applied their method's criteria for good research to the encroaching approach and found it wanting. They resisted the movement, opposed its widespread use, and were skeptical about its contribution. The 1970s and 1980s became a time at least at some universities and within some professional groups of debate and conflict. Although a number of researchers trained in the quantitative tradition began integrating the qualitative approach into their work, others regarded the different methods as competing and in some universities became identified as being in one camp or another qualitative verses quantitative. By the end of the 1980s, doctoral students trained with broader ideas about research began entering the field of educational research and staunch detractors of the qualitative approach began to mellow. By this time there was an armistice of sorts with some researchers preferring one approach over the other and others attempting to integrate the two. Still others switched back and forth, choosing to adjust their approaches to the problems at hand.

ADDITIONAL ISSUES AND DEBATES

Although by the late 1980s and early 1990s the qualitative/quantitative debate had subsided, the qualitative researcher faced other issues and changes that continued being reformulated each decade. Some researchers trained in quantitative approaches who became practitioners of qualitative research as well as qualitative researchers responding to critics who wanted more structure in their research developed more rigid research designs. Authors such as Miles and Huberman advocated formal data collection protocols and standardized data analysis procedures in their work. They championed the development and use of computer software programs to do more thorough and systematic data analysis. Not all qualitative researchers were comfortable with these efforts and charged that such formalization of the method robbed it of its strengths, the discovery of new ways of thinking.

While some qualitative researchers moved toward more structure and accountability another group of scholars went in the opposite direction. People traditionally associated with the humanities (i.e., historical, literary, and philosophical scholars) began to embrace the label of qualitative research. A number of influential books such as James Clifford and George Marcus's *Writing Culture: The Poetics and Politics of Ethnography* and

J. Van Maanen's *Tales of the Field: On Writing Ethnography*, discussed the interpretive nature of qualitative research and how its writing was a product of the author's predispositions and characteristics. Rather than trying to control the author's predilections, a new brand of scholars embraced their own point of view and abandoned the goal of objectivity. They tended to de-emphasize rigorous data collection and concerned themselves less with the empirical world than did more traditional qualitative researchers. In addition to welcoming the humanities into the realm of qualitative research, some qualitative researchers embraced feminist, post-structural, conflict, and critical theory for the underpinnings of their work. Some more traditional qualitative researchers joined their ranks. This group of researchers became much more theory driven than traditional qualitative researchers had been. They also became less data based.

Thus starting in the early 1990s and continuing into the 21st century, qualitative research was pulled in many directions, some of them antagonistic. These movements led some to question whether the term qualitative research had expanded so much that the phrase had lost its meaning. While some cheered the expansion of the field, others thought that qualitative research should return to the basics, to just the elements included in the definition provided above in this entry.

STRENGTHS AND WEAKNESSES

Although general acceptance of qualitative research as defined here exists, some in the field of education continued to express concerns about its use. Qualitative researchers and skeptics would agree that one drawback of the approach is the time it takes to do a good study. Qualitative research is labor intensive; it takes hundreds of hours in the field to collect the data, and data analysis is complex and vexing.

More serious concerns among critics involve the topics of researcher bias and the generalizability of qualitative findings. Qualitative researchers use less standardized instruments and codified procedures than do quantitative researchers. The former approach resembles a craft in which the outcomes are dependent on the skills of the researcher to establish rapport, collect, and then analyze descriptive data. Researchers vary considerably in their talent, interests, points of view, and political disposition. In addition, few external checks on the researcher's data collection and analysis procedures exist. The descriptive data do not readily lend themselves to outside review. Because the data are filtered through the human instrument critics argue that the approach is wrought with observer effect and so its integrity is undermined.

Since most qualitative research involves small samples or studies of one particular classroom or school,

critics question whether what is found can be generalized. They point out, for example, that third grade classes vary so much from place to place and time to time, what is found in a case study of one class tells people little about other classrooms. They point to the danger of thinking that because a person knows one third grade well that person understands third grade classes in general.

Sufficient room is not present here to detail how advocates of qualitative research respond to questions of researcher bias and generalizability. Qualitative researchers acknowledge the unstructured nature of the inquiry and the influence the researcher might have on the outcome. In addressing bias, some point to the careful procedures they have built into the various stages of their research projects. As already indicated, some qualitative researchers, to the consternation of others, have attempted to become even more systematic and formal in their approach, thereby abandoning the evolving design that is characteristic of traditional qualitative studies. Others say the bias that critics are concerned with is overstated. After all, they say, just because other forms of research use instruments and more formal procedures does not mean that the researcher's point of view is not built into the researcher's studies. Further, they point out, in most qualitative studies the researcher carefully states his or her perspective and the concerns that drove the project, a practice that quantitative researchers do not follow.

How do qualitative researchers address the criticism that their findings are idiosyncratic and cannot be generalized? They take the position that critics do not understand the basic premise and logic of the approach. Rather than carrying out rigorous sampling, testing hypotheses, and coming up with a precise list of facts and findings that can be applied across settings and populations, qualitative researchers concern themselves with the dynamics of basic social processes and are interested in developing sensitizing concepts and grounded theory. They believe that behavior is not random and idiosyncratic. If they discover a process or develop a concept in one setting it has to exist in other places. They do not assume that it occurs in all places, for example, called third grade classrooms. Part of the analysis is speculating about other settings in which their findings might apply. Further, they say that if people are interested in generalizability as traditionally defined, it can be checked by additional studies.

Qualitative research comes in many forms and is widely practiced as a part of educational research. Once new and controversial, it has become a regular part of the curriculum for those studying for advanced degrees in education. While it will never replace quantitative approaches, it contributes a different kind of information and understanding to what researchers know about learning in the classroom.

QUASIEXPERIMENTAL RESEARCH

There are two general categories of experimental research—true experimental design and quasiexperimental design (Gribbons & Herman, 1997). The word “quasi” in Latin means *as if* or *almost*. Considering this, quasiexperimental research could be described as a best attempt at an experiment when it is impossible, or not reasonable, to meet all the criteria of a true experiment. This type of research is typically identified as being void of randomization of either subjects or treatment and/or the lack of comparison groups. Yet, there is still an attempt to isolate the treatment. As an overarching

goal, the body of quasiexperimental research attempts to answer questions such as: “Does a treatment or intervention have an impact?” and “What is the relationship between program practices and outcomes?” (Dimsdale and Kutner, 2004).

True experiments are ideal when it comes to being able to isolate any type of statistical relationship, with the potential to infer causality. Even so, prior to designing an experiment, it is necessary to consider a few key elements. Can the individuals and/or other elements in your study be precisely classified? Can you select random individuals or other elements in your study? Is the process of randomization fair to all involved in the study? Should the answer be “no” to any of these questions, quasiexperimental designs then surface. Educational research, and the techniques or interventions that are introduced, seem relatively harmless to the general eye; thus, many researchers continue to emphasize true experiments (Kidder, 1981). It is never so simple; however, as effectiveness, efficiency, and feasibility also need to be considered. There are other ethical considerations as well. If there is any risk of harm from delivering or withholding services to someone in the sample, then an experimental design cannot be employed. For these reasons, in fields such as education, psychology, and criminal justice, quasiexperimental research is often utilized. As a whole, the research community tends to support the use of and recognize the utility of quasiexperimental research (Campbell & Stanley, 1963; Cook & Campbell, 1979).

A COMPARISON TO EXPERIMENTAL RESEARCH

Quasiexperimental research and experimental research both attempt to create a design scheme in which the concluded results can be thought of as the best, most logical solution to the question at hand. Quasiexperimental designs tend to do this through a comparison of existing groups. Experimental designs accomplish the same goal through random assignment of individuals to interventions or treatments (Michigan State University, College of Education, 2004).

Experiments, especially large-scale, are designed to control for the influences of extraneous variables. The goal is to allow for a maximum level of certainty regarding the impact of an intervention. Specifically, experimental designs must have random selection of subject, use of control groups, random assignments of individuals to the control and experimental groups, and random assignment of groups to the intervention (Henrichsen, Smith & Baker, 1997). The strongest comparisons are made through the ability to conduct a true experiment (Gribbons & Herman, 1997). To this extent, quasiexperimental designs attempt to rule out unrelated explanations so that

the outcome can be attributed only to the experimental intervention. The task is not as straightforward, but through efforts such as matching subjects and statistical analysis, the true experiment is mimicked (Morgan, Gliner & Harmon, 2000; SERVE Center, 2007). Specifically, *trend* replaces the word *cause* in quasiexperimental research. The goal of quasiexperimental research is to discover the one trend that is a result of the treatment or intervention. Clearly, this is not a simple or direct task and error exists in that process.

The data collection and analyses are a point of overlap and a point of distinction between experimental and quasiexperimental research. While standardized assessments are utilized in both approaches, they are the singular mechanism to the experimental design. In contrast, quasiexperimental design also utilizes such means as surveys, interviews, and observations. The statistical techniques also have the same appearance, clean and simple. In contrast, quasiexperimental research uses an array of analysis techniques including the t-test, but also extending to correlation, regression, and factor analysis (Dimsdale & Kutner, 2004).

Quasiexperimental designs are typically employed if random assignment is not practical, or even impossible. Without randomization, typical issues surface. Even with a comparison group, the concern surfaces of how alike the groups are from the onset. Also, with the loss of control in quasiexperimental designs, it is of concern whether both groups are in some manner exposed to the intervention, intentionally or not. Nonetheless, the biggest weakness of quasiexperimental designs may also indicate the greatest strength—a broader scope of the research design. The controlled, randomized design of true experiments typically lends itself to a very limited, narrow view of the topic of interest (Gribbons & Herman, 1997). In all cases, when human subjects are involved, there is never a 100% guarantee that the results of an intervention can be completely attributed to the intervention itself, with no regard for the opinions and practice of the individuals involved. Simply stated, true experiments work well in laboratory settings. Quasiexperiments work well in natural settings (Schoenfeld, 2006).

EXAMPLES OF QUASIEXPERIMENTAL RESEARCH

Quasiexperimental research is designed with the intent to be as much like a true experiment as possible. The two traditional platforms are: (1) matching studies, in which participants are compared with individuals that are comparable on variables of interest that do not receive the intervention; and (2) interrupted time series, in which observations made prior to an intervention are compared

again and additional observations are made after the intervention has happened. These types of studies present themselves in various formats (Prater, 1983).

The general goal of quasiexperimental research is to investigate cause and effect relationships. This approach to research allows for greater understanding of program features and practices. Because there is a loss of control in the quasiexperimental design, it is necessary for the researcher to decide what and when to measure (Dawson, 1997). What follows is a sample outline of designs. An *X* represents the group being exposed to a treatment or intervention. An *O* represents an observation or measurement. Temporal order of events is designated from left to right. The dotted line in each design is an indication of the lack of random assignment of subjects to the groups (Prater, 1983).

One-group posttest design

X O

The One-Group Posttest Design is a one-shot case study. It simply has a treatment, *X*, and posttest, *O* with no control group. This design is best implemented as an evaluation model. It should be used only when there is no available comparison group or pretest data.

Static-group comparison design

X O

 O

In the Static-Group Comparison Design, a pre-test, *X*, is given to only one group, while the post-test, *O*, is given to both the control and experimental group. This design is comparable to the One-Group Posttest Design, with the addition of a control group for comparison purposes. No randomization is present, instead two groups are arbitrarily selected, and one is labeled as experimental and the other control.

Nonequivalent control-group design

O₁ X O₂

O₂ O₂

The most common quasiexperimental design is the Nonequivalent Control-Group Design, illustrated above. The design includes at least an experimental and control group. It mirrors the Pretest-Posttest control group experimental design, but instead of randomization,

naturally occurring comparison groups are selected to be as alike as possible (Gribbons & Herman, 1997).

Time series design

With a Time Series Design, observations are taken (in this case three) to establish a baseline; a treatment then occurs, X , followed by additional observations being made. From this, an estimate of the impact the treatment made is computed (Gribbons & Herman, 1997; Morgan, Gliner & Harmon, 2000). The design can be employed to establish a baseline measure, describe a change over time or to keep track of trends. Data are almost always presented in a graph.

Multiple time series design

The Multiple Time Series Design is simply an extension of the Time Series Design with the addition of a comparison group. It attempts to model what would have happened to the experimental group if the treatment or intervention had not taken place. The addition of the control adds credibility, even without randomization.

Equivalent materials design

In the Equivalent Materials Design, different, equivalent materials are represented throughout with $M_{a,b,c,d}$. The treatments and repeats of treatments, $X_{0,1}$, are applied and then observed. In addition to the aforementioned designs, there are elaborate extensions, such as the Latin-square Design (Fortune & Hutson, 1984).

ROLE OF QUASIEXPERIMENTAL RESEARCH IN EDUCATIONAL RESEARCH

It was not until the late 1900s that educational reform gave credence to research. Prior to that, untested interventions and innovations were commonplace. The U.S. government has come to demand a research base, as demonstrated by the Comprehensive School Reform Demonstration legislation of 1997 and the No Child Left Behind Act. In both

cases, the emphasis is in the application of experimental or quasiexperimental research (Slavin, 2003).

Campbell and Stanley (1963) speak to traditional experimental and quasiexperimental methods. Cook and Campbell (1979) continued to explore these methods, building upon early investigations of validity. In 1993 Parker reviewed and synthesized both the works and further added to the mound of threats to validity. At the turn of the century, various authors were continuing to write about the issue of what constitutes an experimental design and the issues associated with a less than perfect experiment. The presence of true experimental designs in educational research has not been prevalent over time largely due to methodological constraints and on some accounts, more logistical issues like money and time. It is frequently not practical to randomly assign individuals to control and experimental groups, like in a clinical setting where groups are already intact (Dimsdale & Kutner, 2004; Heppner, Kivlighan & Wampold, 1992). Quasiexperimental designs offer a plausible solution to these dilemmas.

Other issues that typically surface in educational research include, but are not limited to, confounding and the assumption of independence. Independence states that the measure for an individual is independent of the measures of other individuals. Randomization of subjects is the only way to insure this. Confounding is another concern. When a variable in a research design is not controlled, but should be, it is identified as a confounding factor. Given that confounding cannot be dealt with in terms of statistical notions alone, quasiexperimental designs, and for the most part educational research as a whole, always have this as a limitation (Pearl, 2000).

If evidence-based school reform continues to be the golden standard, quasiexperimental research will play an instrumental role. Quasiexperimental research, and the scientifically based results that go along with it, can provide the educational community with a variety of models that have been shown to be effective. Reading First and other similar initiatives have created evidence-based reform that can be sustained. Because of this, it is plausible that the rigor associated with quasiexperimental designs will become commonplace (Slavin, 2003; U.S. Department of Education, 1998; U.S. Department of Education, 2002).

ANALYTIC APPLICATIONS APPLIED IN QUASIEXPERIMENTAL RESEARCH

Valentin (1997) made a claim that with an understanding of eight statistical procedures, it is reasonable to have an understanding of 90% of quantitative research. Experimental designs lend themselves to straightforward, often simpler, statistical analysis than quasiexperimental designs. Advanced statistical procedures are typically

necessary in quasiexperimental research, largely due to the lack of randomization (Dimsdale & Kutner, 2004).

Two specific examples include multiple regression analysis and factor analysis. *Multiple regression analysis* is a statistical application that is utilized in studies in which impact is being measured. Using statistical methods, a control group is simulated, and multiple adjustments can be made for outside factors. Thus, the control that is in the design of an experiment is inserted through analytical techniques (SERVE Center, 2007). *Factor analysis* is a useful technique when a study has a large number of variables. This statistical application allows for a reduction in the number of variables while detecting possible relationships between those variables of interest (Dimsdale & Kutner, 2004). It is commonly applied when data is collected through a survey, especially when the survey contains a large number of items. *Analysis of covariance* (ANCOVA) is yet another analytical technique employed to increase the strength of the quasiexperimental design. By making compensating adjustments, ANCOVA reduces the effects of the initial differences between groups. This again is an attempt to respond to the lack of randomization.

STRENGTHS AND WEAKNESS OF QUASIEXPERIMENTAL RESEARCH

When considering what type of design to employ in a study, it is important to consider both validity and practicality. In general, quasiexperimental research is more feasible, given the typical time and logistical constraints. At the surface level, an easily identifiable weakness of employing quasiexperimental research, in contrast to a true experiment, is the lack of random assignment. Without random assignment, internal validity is reduced, and causal claims become quite difficult to make (Prater, 1983).

On the other side, quasiexperimental designs tend to present the situation under investigation in real-world conditions, increasing the external validity. Typically, quasiexperimental designs are pre-existing constructions. Because of this, fewer variables are able to be controlled; yet another factor limiting the ability to make causal claims (Henrichsen, Smith & Baker, 1997).

With the implementation of the No Child Left Behind statute, educational research put forth an agenda of scientifically based research. Shavelson and Towne (2002) outline criteria necessary for a scientific study, which include: direct, empirical investigation of an important question; consideration for the context in which the study took place; alignment with a conceptual framework; careful and thorough reasoning; and disclosure of results. Quasiexperimental research makes the

mark by meeting each criterion listed. While the controlled, experimental design is the ideal, at least statistically, when an experiment is not possible or practical, the best approach is to identify and eliminate threats to validity through the implementation of a quasiexperimental approach (Borg & Gall, 1989).

QUESTIONING

Questioning consumes a considerable proportion of time in classrooms. It occurs most often within recitations, characterized by the initiate-respond-evaluate (IRE) pattern of discourse, as well as in more open-ended discussions. Interest in questioning as an instructional tool can be traced back to the fourth century BCE as evidenced in the Socratic dialogues recorded by Plato (424/423–348/347 BCE). In the 21st century, teachers use questions to manage student behavior and classroom activities, to promote students' inquiry and thinking, and to assess students' knowledge or understanding. The focus of this entry is predominantly on teachers and students' use of questions as a tool to promote inquiry, thinking, and ultimately learning.

RESEARCH STRANDS AND CURRENTS

The research on questioning is considerable both in volume and topics investigated. Research on questioning has investigated the incidence and types of questions teachers ask (e.g., Guszak, 1967); the sources of teacher questions (e.g., Shake & Allington, 1985); the effect of teacher questions as compared to other instructional methods (e.g., Gall, Ward, Berliner, Cahen, Winne, Elashoff, & Stanton, 1978); the effects of different types of questions (e.g., Wright & Nuthall, 1970); the effects of waiting for students to respond after asking questions (e.g., Rowe, 1986; see also Tobin, 1987); training teachers to use certain types of questions (e.g., Galassi, Gall, Dunning, & Banks, 1974); teaching students how to answer questions (e.g., Raphael & Wonnacott, 1985); teaching students to generate their own questions (e.g., Commeyras & Sumner, 1998), and the psychology of question asking and answering (e.g., Graesser & Black, 1985). Table 1 lists the major reviews of this research.

Two trends are apparent in the research. One is movement from a focus on questions as isolated events

to a focus on questions embedded within larger spatial and temporal contexts, including the contexts created by the ongoing classroom discourse. Up until the early 1980s, researchers classified and counted teacher questions and attempted to relate the frequencies of different types of questions to student achievement. Researchers employed correlational studies that capitalized on existing variation in teacher questioning behavior or experimental studies in which they manipulated teachers' use of questions (see Brophy & Good, 1986). In the late 1980s and 1990s, researchers examined questions as "sites of interaction" (Nystrand, 1997) and their relationship to student learning. These sites of interaction included the question asked, students' responses to the question, the teacher's valuation or follow-up to students' responses, and even the genre of the entire classroom discourse. Researchers also developed questioning routines to help students talk and think together in cooperative or collaborative learning environments. These routines included *Reciprocal Teaching* (Palincsar & Brown, 1984), *Questioning the Author* (Beck, McKeown, Hamilton, & Kucan, 1997), and various methods of structuring discourse to promote learning among peers (King, 1999).

This trend was motivated by research in sociolinguistics and language acquisition that highlighted the distinction between language form and communicative function, showing that the meaning of a question depended on its context of use. This context includes not only the situational context but also the contexts created by speakers in the give and take of discussion. From a sociolinguistic perspective, teacher questions are mutually constructed by teachers and students (Carlsen, 1991). Hence, the cognitive impact of questions depends on their placement within the larger discourse, the backgrounds of the students, relations among teachers and students, and other factors. (Cazden, 2001).

Another trend apparent in the research is movement from a focus on teacher-generated questions to a focus on student-generated questions. This trend is apparent in the research on questioning routines embedded in cooperative or collaborative learning environments mentioned earlier. It can also be seen in research on the K-W-L technique developed by Ogle (1986), a technique that requires students to ask themselves questions to promote comprehension of expository texts ("What do I Know about the text?" "What do I Want to learn from the text?" "What did I Learn from the text?"). It is also evident in research by Commeyras (1995; Commeyras & Sumner, 1998) on the benefits of giving students responsibility for posing their own questions for discussion in response to literature. Wong (1985) reviewed 27 studies of student question generating and found positive

effects on students' reading comprehension in the majority of studies. Rosenshine, Meister, and Chapman (1996) conducted a meta-analysis of 26 studies of student questioning and also found positive effects on students' comprehension.

QUESTIONS THAT VARY BY COGNITIVE DEMAND

Questions are typically classified by the nature of the cognitive demand they are presumed to make on students. Most classifications define cognitive demand in terms of Bloom's 1956 taxonomy of learning or some variant of it. Bloom defined learning in terms of six levels of increasingly complex requirements: knowledge, comprehension, application, analysis, synthesis, and evaluation. Lower-order questions are presumed to elicit a student's knowledge and comprehension of a topic or text; higher-order questions are presumed to elicit a student's application, analysis, synthesis, or evaluation of a topic or text.

A related framework often used in research in reading and the teaching of reading is Pearson and Johnson's

1978 taxonomy of questions or, more accurately, question-answer relations. This framework classifies questions according to source of information that must be used by the reader to generate a response: *textually explicit*, in which the information required for answering the question is stated explicitly in the text ("reading the lines"); *textually implicit*, in which the information required for answering the question is in the text but has to be inferred by integrating material from different parts of the text ("reading between the lines"); and *scriptally implicit*, in which the information required for answering the question involves the reader's store of prior knowledge ("reading beyond the lines").

Research in the United States as well as in other English-speaking countries has documented a higher incidence of lower-order than higher-order questions in classrooms for much of the 20th century. Stevens' 1912 study was possibly the first systematic study of teacher questioning in the United States. He observed teachers in 100 high-school classrooms in six subject areas and found that at least two-thirds of the questions teachers asked focused on recitation and memory of facts. Studies in

the 1970s and 1980s (e.g., Sirotnik, 1983) showed little change in the preponderance of lower-order over higher-order questions (see Klinzing & Klinzing-Eurich, 1988). Data collected by Nystrand in 1997 also suggest little change. Nystrand observed the instructional practices in 58 eighth-grade and 54 ninth-grade language arts and English classes in eight Midwestern communities in the United States. He reported that 64% of questions in the eighth-grade classes involved recitation and reporting of facts whereas only 36% involved high-level thinking (analysis, generalization, speculation). Results in the ninth-grade classes revealed a somewhat different picture with 54% of questions involving recitation and reporting.

Similar trends are evident in observational studies of reading instruction in elementary grades. Guszak's 1967 study examined the kinds of questions 12 teachers asked in selected second-, fourth-, and sixth-grade classrooms in Texas during reading group lessons. He found that 70% of questions were recognition or recall questions that focused on literal comprehension. O'Flahavan, Hartman, and Pearson (1988) conducted a replication and extension of Guszak's study, videotaping teacher-led reading groups and story discussions conducted by 15 teachers in grades 2, 4, and 6 in four schools in Illinois. Results showed a lower incidence of recognition and recall questions (43%). Overall, relative to Guszak's findings, they noted a shift from literal questions to more inferential questions. However, other studies conducted at the time continued to report a preponderance of lower-level, text-based questions in reading lessons (Gambrell, 1983; Shake & Allington, 1985; Weber & Shake, 1988). Observational studies by Taylor and Pearson (Taylor, Pearson, Clark, & Walpole, 1999, 2000; Taylor, Peterson, Pearson, & Rodriguez, 2002; Taylor, Pearson, Peterson, & Rodriguez, 2003, 2005) of reading instruction in grades 1 to 5 in a number of high-poverty schools in the United States have shown similar results. Across all grades, they observed a relatively small amount of higher-level questioning (e.g., only 16% of the teachers in grades 1 to 3 were frequently observed asking higher-level questions).

It is presumed that asking more higher-order questions contributes to greater gains in students' high-level thinking, learning, and achievement. This presumption has received only weak support. Rosenshine (1971, 1976) and Dunkin and Biddle (1974) conducted reviews of studies relating teacher questioning to student learning, many of which were correlational studies, and found that results were inconsistent (in some studies, even lower-order questions were found to be more effective). Winne (1979) reviewed 18 experimental and quasi-experimental studies on levels of teacher questioning and concluded that "whether teachers use predominantly higher cognitive

questions or predominantly fact questions makes little difference in student achievement" (p. 43). Redfield and Rousseau (1981) conducted a meta-analysis of 14 experiments, 13 of which overlapped with those reviewed by Winne, and found that a predominant use of higher cognitive questions had an overall positive effect on student achievement (mean effect size = 0.73). Samson, Strykowski, Weinstein, and Walberg (1987) conducted another meta-analysis of 14 experiments, most of which overlapped with those of the previous reviews, and obtained results more in tune with the earlier findings by Winne and others. Samson and colleagues reported only a small positive effects of higher cognitive questions on student achievement (median effects size = 0.13). Gall and Artero-Boname (1995) attributed the inconsistency in results to a number of factors, not the least of which was that the individual studies failed to take account of the larger instructional context in which questions occurred.

Other studies have attempted to examine the role of questions within the larger instructional context but have still not shown consistent results. Nystrand's 1997 large-scale correlational study showed no relationship between the cognitive level of questions and students' performance. Taylor and Pearson's series of correlational studies of reading instruction in high-poverty schools (Taylor et al., 1999, 2000; Taylor et al., 2002; Taylor et al., 2003, 2005) have shown more consistent relationships between higher-level questioning and students' growth in reading and writing. However, even in these studies, there were inconsistencies. In their 2005 study, they found that high-level questioning made a modest contribution to growth in students' reading fluency but had no relationship to growth in their comprehension or writing.

QUESTIONS THAT VARY BY EPISTEMIC ROLE

Another way of classifying questions is in terms of the epistemic role they afford students. Authenticity and "uptake" are key features in giving students a role in orchestrating their own learning. Questions that give students considerable control over their learning are "authentic questions" questions that the teacher is genuinely interested in exploring and that evoke a variety of responses from students (in other words, the answer is not prespecified). By contrast, questions that give students little to no control are known-answer questions (sometimes called "test questions") that allow only one possible right answer. Questions that incorporate responses from students, called uptake, offer another way of building on students' contributions and affording them a role in learning. This way of classifying questions

is not independent of the level of cognitive demand described earlier. Authentic questions are more likely to elicit application, analysis, synthesis, or evaluations of information; whereas known-answer questions are more likely to elicit recall or literal understanding.

Nystrand (1997) and Applebee, Langer, Nystrand, & Gamoran (2003) documented the incidence of authentic questions and uptake in large numbers of language arts and English classes in middle and high schools in various states in the United States. Nystrand's data showed that, in the eighth-grade classes, only 10% of teacher questions were authentic and only 11% exhibited uptake. In the ninth-grade classes, 27% of teacher questions were authentic and 26% exhibited uptake (Nystrand noted that much of the increase in the incidence of authentic questions in the ninth grade was due to the use of authentic questions about nonacademic topics). Applebee and colleagues' data for grades 7, 8, 10, and 11 showed that 19% of teacher questions were authentic and 31% exhibited uptake.

Nystrand's 1997 correlational analyses showed that, in eighth-grade classes, authentic questions and those exhibiting uptake were significantly related to students' learning. However, in ninth-grade classes, results showed that authentic questions were not related or were even negatively related to learning. Questions exhibiting uptake still showed a significant and positive contribution. Further analyses showed that authentic questions had a positive relation in high-track classes but a negative relation in low-track classes. This was because most of the authentic questions in high-track classes pertained to literature, whereas most in low-track questions were about topics not related to literature. Nystrand concluded that authentic questions do not invariably produce learning but they at least signal to students "that *their* ideas . . . are important and can provide opportunities for learning" (p. 90). The 2003 study by Applebee and colleagues largely confirmed the role of authentic questions and uptake, in combination with other discussion-based approaches to developing understanding, as contributors to student learning.

WHAT IS KNOWN AND NOT KNOWN ABOUT QUESTIONING

The considerable volume of research on questioning has shed light on a number of issues regarding questions as a tool for learning. It is known that the incidence of higher-order and authentic questions is low relative to lower-order and known-answer questions. It is known that waiting for students to respond to questions leads to enhanced quality of responses and improved student achievement. It is known that teachers can be taught to ask certain types of question, and that students can be

taught how to answer questions based on the relationship to the text. It is also known that promoting student-generated questions has positive effects on learning.

However, there are several enduring issues about which research is unclear. It is not known whether teacher questioning as an instructional tool is any better than other instructional methods. Indeed, there is research and argument that a number of alternatives to questioning (e.g., declarative statements) are associated with longer and more complex responses from students (Dillon, 1985; 1991). It is not known, with any reasonable surety, that asking higher-level questions contributes cognitive benefits for students. Asking higher-level questions seems to have at least a small positive effect on learning but the inconsistency in results on this issue remains an enigma. Asking authentic questions and questions that involve uptake has more reliable associations with student achievement, but only to the extent that they assign meaningful epistemic roles to students and little is known about the context and classroom culture that shape such conditions. These are questions about questions that are in need of exploring.

REASONING

Reasoning has long been a topic of study in logic and philosophy. Logical philosophical approaches are typically concerned with formal and epistemic aspects of reasoning; describing normative models of sound or valid reasoning. However, philosopher David Hume (1711–1776), who produced some of the most influential work on inductive reasoning, recognized the limitations of purely logical accounts of reasoning and noted that psychological processes were vital to a full account of reasoning. Formal or logical approaches to reasoning specify the syntactic form of valid inferences (i.e., those that do not lead to logical contradictions). In contrast, psychological approaches to reasoning explain cognitive performance or how people actually reason. Inferences that are syntactically valid from a logical perspective may be practically uninformative. For example, given the premises (a) Jane is taller than Mary, and (b) Mary is taller than Jill, it would be logically valid to deduce the following inference: Jane is taller than Mary, and Mary is taller than Jill, and Jane is taller than Mary and Jill. However, people are unlikely to make this particular inference from the premises (a) and (b) because it is not parsimonious. Instead, people are far more likely to draw the logically valid and parsimonious conclusion that Jane is taller than Jill.

People's knowledge of the world places pragmatic constraints on how they reason (Brewer & Samarapungavan, 1991; Giere, 1988; Johnson-Laird, 2006; Cheng, 1997). Classical models of reasoning based on logic or the laws of statistics and probability assume an ideal reasoner, unconstrained by cognitive resources. However, Gigerenzer & Goldstein (1996) argue that people display bounded rationality. Their reasoning is constrained by a number of factors such as the limited capacity of working memory and their cognitive goals (they often reason to find an acceptable solution, not necessarily the “best” solution).

DEFINITION OF REASONING

From a psychological perspective, reasoning may be defined as the set of mental processes used to derive inferences or conclusions from premises. Reasoning helps to generate new knowledge and to organize existing knowledge, rendering it more usable for future mental work. Reasoning is therefore central to many forms of thought such as scientific, critical, and creative thinking, argumentation, problem solving, and decision making. Each of these more complex forms of thought can employ inductive, deductive, and abductive reasoning which are described below.

Induction. *Inductive reasoning* is ampliative; it generates new knowledge. Inductive reasoning supports inferences but does not guarantee that the inferences are true. Vickers (2006) characterizes inductive reasoning as “contingent” (i.e., dependent on past experiences and observations). There are many forms of inductive reasoning such as *enumerative induction* and *analogical reasoning*. The best known form is enumerative induction in which

the general properties of a class are inferred from a specific set of empirical observations. For example, upon observing that all the birds in the neighborhood have wings and fly, a person infers that all birds have wings and fly. Generalizations of this kind, though commonplace in human reasoning, are clearly fallible (ostriches and penguins are birds and have wings, but do not fly). The preceding example illustrates a general epistemic problem with inductive inferences, which philosophers refer to as the problem of underdetermination.

Analogical reasoning is another form of inductive reasoning that is important in generating new knowledge. Analogical reasoning involves the transfer of knowledge elements and relationships among knowledge elements (e.g., object properties and property relations such as correlated features) from a well-known domain, a “base,” to an unknown or partially known domain, a “target” (see Gentner, Holyoak, & Koikinov, 2001). For example, the analogy of a biological cell as a factory allows people to transfer knowledge about how a factory works (it has parts that are specialized to perform certain tasks and that operate together to maintain the functioning of the whole) to understand how a cell works. Analogical reasoning is often employed in instruction to help student understand new concepts by analogical transfer from more familiar concepts (Clement, 1993; Baker & Lawson, 2001; Thagard, 2006). Inductive reasoning presumes principles of regularity or continuity in the world that allow the drawing of inferences about new instances from past experience. Induction plays a role in concept formation and concept learning in every domain of knowledge from natural language to science.

Deduction. Deduction refers to processes of inference which guarantee logically valid conclusions from a set of premises. In other words, assuming that the premises are correct, the conclusions deduced from these premises must also be correct. Transitive inferences of the kind described earlier (Jane is taller than Mary; Mary is taller than Jill; therefore Jane is taller than Jill) are one form of deductive inference. Deduction is a constituent of many varieties of cognitive performance such as text comprehension, scientific and mathematical reasoning, and argumentation. Deduction also plays an important role in categorical reasoning. If, for example, scientists were to discover the remains of a hitherto unknown animal in permafrost, conduct DNA analysis on the remains and conclude that the animal was a mammal, they could then deduce that this previously unknown species had defining mammalian characteristics (e.g., it gave birth to its young and had body hair). One of the main cognitive functions of deductive reasoning is to organize knowledge in ways that allow one to derive parsimonious conclusions from sets of premises.

Abduction. The term *abduction* was coined by Charles Peirce (1839–1914) to refer to a third mode of inference that was distinct from induction and deduction and played a crucial role in scientific reasoning and discovery. Adductive reasoning is a form of reasoning in which individuals start by attending to a particular phenomenon and try to construct a hypothesis that best explains their observation. The process is often called inference to the best explanation (Lipton, 1961; Thagard & Shelley, 1997). Many causal inferences are abductive in nature.

An example of abductive reasoning would be an inquiry into a car crash in which investigators try to reconstruct what happened from forensic evidence (e.g., patterns of damage to a car and its surroundings, data from physiological and toxicological exams conducted on the driver and passengers). From the forensic data, they reconstruct the most plausible or likely explanation for the crash.

SCIENTIFIC REASONING

A classic model of scientific reasoning in philosophy is the hypothetico-deductive model developed by Karl Popper (1902–1994) (1959, 1972). This model posits that hypotheses are deduced from theory and empirically verified by conducting tests that attempt to falsify them. Hypotheses that withstand repeated attempts at falsification may be regarded as better corroborated by the existing evidence than those that do not. However, according to Popper (following Hume), no matter how often a hypothesis is corroborated by empirical evidence, there can be no certainty that it is true.

Post-Popperian scholarship suggests that scientific reasoning is multi-faceted and includes inductive, deductive, and abductive reasoning (Giere, 1988). It is perhaps most useful to think of scientific reasoning as an umbrella term that encompasses all forms of inference that further the generation, evaluation, and revision of scientific knowledge. One important source of scholarship on scientific reasoning comes from the area of science studies. Much of this research draws upon the methods and data of historical research to understand how science is done (Conant, 1957; Giere, 1988; Kuhn, 1962; Thagard, 1990). Such studies analyze archival data, including the laboratory notebooks, correspondence, and the publications of scientists. Dunbar, Giere, Knorr-Cetina, and Sahdra and Thagard have undertaken cognitive analyses of the research practices of working scientists. Naturalistic research has highlighted the role of interpretation in scientific reasoning. Laudan (1990) suggests that scientific judgments are often based on pragmatic criteria such as the compatibility of new ideas with those that are considered to be “well founded.”

VARIATIONS IN REASONING ACROSS DISCIPLINES

Naturalistic research suggests that reasoning within different disciplines and sub-disciplines is shaped by the specific conventions of disciplinary practice such as methodological conventions for collecting, analyzing, presenting, and evaluating data (Ericsson, Charness, Hoffman, & Feltovich, 2006; Giere, 1988; Thagard, 2003; Sahdra & Thagard, 2003). Deductive reasoning may play a greater role in disciplines or sub-disciplines with well-developed formal theories; for instance, certain areas of mathematics and physics. Inductive and abductive reasoning may play a greater role in contexts in which different causal patterns can result in similar outcomes (medical diagnosis) or where particular configurations of events are unique and unlikely to be repeated exactly (forensic science). For instance, Wineburg (1998, 1999) argues that history is a discipline with its own unique contextualized patterns of reasoning. It should be noted that most disciplines employ varied forms of reasoning. Although mathematics has historically been characterized as a deductive discipline (Kitcher, 1979; Netz, 2005; Russell, 1903), Kitcher (1985) and Lakatos (1976) suggest that inductive reasoning plays an important role in mathematical thinking.

DEVELOPMENT OF SCIENTIFIC REASONING

Research indicates that some aspects of reasoning develop early, even before the onset of formal schooling or instruction, and may be part of the basic cognitive machinery of humans. There is considerable evidence that people employ forms of inductive and abductive reasoning to construct concepts about the natural world spontaneously, even in the absence of formal instruction in science (Bailargeon, 2004; Carey, 1985; diSessa, 1993; Hatano & Inagaki, 2004; Vosniadou & Brewer, 1992). Young children can use prior knowledge of causal mechanisms to reason causally in new contexts and to make causal inferences. Brown's 1990 research shows that by the age of 3, children are able to use their causal knowledge about physical mechanisms to select tools of the right shape and material to help them retrieve a physical object. Given a set of tools of the same shape (rakes or hoes) but different materials, the children in Brown's experiments rejected non-rigid or "squishy" tools in favor of those that were made of rigid materials and would pick up the desired objects without bending or breaking.

Children can use category-based induction to infer new biological knowledge. Two-year-olds expect animals that belong to the same category or "kind" to have the same underlying properties (Gelman & Coley, 1991; Lawson & Kalish, 2006). Young children are also able

to use analogical reasoning to help them solve novel problems (Goswami, 1989; Holyoak, Junn, & Billman, 1984). Both adults and young children are able to induce causal structures from observed patterns of covariation in data (Cheng, 1997; Glymour, 2001; Sobel, Tenenbaum, & Gopnik, 2004). Preshcoolers can use Bayesian knowledge about causal patterns to infer causal structure from data in some circumstances. In experiments, children observe patterns of data in which an outcome *C* varies as two putative causes *A* and *B* are presented either individually or together. For example, they might observe that *A* alone is followed by *C*, and *A* and *B* together are followed by *C*, but *B* alone is not followed by *C*. Children ages 3 and 4 are able to infer from such patterns that only *A* and not *B* causes *C* (Sobel, Tenenbaum, & Gopnik, 2004; Schulz and Gopnik, 2004).

Certain aspects of reasoning develop late and may not be evident even in the thinking of college-educated adults in the absence of specific training. Research shows that complex forms of deductive reasoning such as syllogistic and conditional reasoning start to emerge in the late elementary school years and continue to develop through adolescence (Bara, Bucciarelli, & Johnson-Laird, 1995; Ward & Overton, 1990). One important psychological model of scientific reasoning is Klahr and Dunbar's model which characterizes scientific discovery as the search for hypotheses to account for patterns of relevant evidence. The model posits that during discovery, people simultaneously search in two related spaces, a "hypothesis space" and an "experiment space." When trying to account for patterns of data, people either invoke hypotheses from prior knowledge or induce them from the data. They then search for an experiment that can help them choose among rival hypotheses. The work of Klahr and his colleagues suggests that adolescents and adults have difficulty with the use of appropriate experimental design and evidence evaluation strategies. For instance, many people do not spontaneously employ a "control of variables" strategy in complex scientific discovery tasks where there are several potential causes that might influence an outcome (Chen & Klahr, 1999; Klahr, 2000).

On tasks that require the interpretation of covariation evidence (for instance, rates of illness among people who have eaten different combinations of foods) research shows that both children and adults often make unwarranted causal inferences from confounded experiments (Kuhn, 1989, 1991; Kuhn & Dean, 2004). Additionally, people reason differently about identical patterns of covariation evidence depending on whether the variables under consideration are believed to be causal or non-causal based on prior knowledge (Kuhn, 1991; Schauble, 1996). These findings parallel earlier work by Kahneman and Tversky (1979) on errors and biases in human reasoning which shows that given the same objective

probability data, people's reasoning about probable gains differed from their reasoning about probable losses. Kuhn & Dean (2004, 2005) argue that part of learning to reason scientifically is the ability to generate genuine scientific questions (ones to which the answer is not known) that can be fruitfully addressed by empirical evidence. They point out that in richer and more realistic knowledge building and evaluation contexts, there is considerable variability in reasoning both across individuals (for example, by age and expertise) and within individuals (for instance, across domains and tasks). Thus, one aspect of developing reasoning competence is the range of contexts to which different forms of reasoning can be successfully applied.

THE ROLE OF CONCEPTUAL KNOWLEDGE

As noted earlier, one factor that influences how people reason is the nature of the conceptual base from which they reason. People reason with and about concepts, and one problem in evaluating reasoning is that different individuals may interpret the same situation differently and bring different assumptions to bear in reasoning. Prior knowledge and belief facilitate reasoning in some contexts. The work of Brown (1990) shows that prior knowledge facilitates causal reasoning even in young children. Pragmatic knowledge improves deductive reasoning on conditional reasoning tasks (e.g., tasks of the logical form: If *P* then *Q*) for both children and adults (Cheng & Holyoak, 1985; Girotto, Light, & Colbourn, 1988). Samarapungavan (1992) has shown that elementary school children are able to reason scientifically in theory choice tasks if the competing theories are both plausible. For example, given two equally plausible theories, they prefer the theory that is consistent with the available empirical evidence. They also prefer theories that explain a wider range of data to narrower theories.

Prior knowledge and belief can also impede valid reasoning. For example, Kahneman and Tversky (1973) showed that people's predictions about the likelihood of future events were often based not on the actual (known) frequencies with which these events occurred in a target population (the "base rate") but on other heuristics such as how easily an example of the event came to mind (availability). In the context of scientific investigation tasks, differences in conceptual models lead people to adopt different strategies of investigation and evidence interpretation. When investigating electricity in a simulated microworld (a computer-based dynamic system that simulates how electricity works) called *Votlerville*, college students with more sophisticated initial causal models of electricity learned more than students with less sophisticated models because they used more fruitful investiga-

tive strategies and engaged in better reasoning (Schauble, Glaser, Raghavan, & Reiner, 1992).

SOCIOCULTURAL FACTORS IN REASONING

In contrast to traditional psychological approaches which focus on individual reasoning, sociocultural theories emphasize the socially shared or co-constructed aspects of reasoning (Boyd & Richerson, 2005; Bruner, 1966; Latour & Woolgar, 1986; Knorr-Cetina, 1999; Rogoff, 1990; Vygotsky, 1978). Jean Piaget (1896-1980) (1945) believed that encountering beliefs and opinions that countered one's own in the course of social interaction provided a powerful form of cognitive challenge which impelled a person to reason. The science studies research discussed above illustrates how sociocultural contexts and practices shape and support scientific reasoning in a variety of ways. Individuals learn prototypical forms or patterns of reasoning as they are acculturated into the practices of their discipline. For instance, social scientists become adept in the use of statistical models for reasoning about patterns of evidence. Giere (1988) and Knorr-Cetina (1989) have noted the role of peer discourse, both formal and informal (e.g., peer review, research group discussions), in shaping the reasoning and knowledge of scientists engaged in discovery. Expert reasoning is supported by cultural tools such as charts, laboratory notebooks, and computer programs for statistical analysis or data modeling (Latour, 1990). Such inscriptional tools allow users to externalize and share both the processes and products of reasoning and reduce cognitive load during complex tasks. For example, using computer programs such as SAS to perform multivariate regression reduces the computational burden of reasoning about covariation evidence with large data sets.

INSTRUCTIONAL STRATEGIES

Can good reasoning be developed through instruction? The research suggests that a variety of instructional approaches and strategies can support the development of reasoning in students. In some circumstances, explicit instruction and modeling can help students acquire patterns of reasoning that they are unfamiliar with (Nisbett, Fong, Lehman, & Cheng, 1987). Students who are explicitly taught to use a "control of variables" strategy on scientific reasoning and discovery tasks are more likely to transfer and use this strategy in novel reasoning contexts than students who receive no explicit instruction and are left to discover the strategy on their own (Klahr & Nigam, 2004).

Instructional scaffolding can be used to support and enhance students' reasoning. Adult support and guidance in the form of hints, questions, and prompts during classroom discourse can help students gain awareness and

control over their reasoning (Hogan, Nastasi, & Pressley, 2000; Gleason & Schauble, 1999). Cultural tools (especially computer technology) can be used to enhance student thinking and reasoning in the classroom (Polman & Pea, 2001; Roschelle, Pea, Hoadley, & Gordin, 2000).

In addition to specific strategies to foster reasoning, many educators have discussed the general characteristics of learning environments that support habits of thought and reasoning. These include the use of knowledge-rich, challenging, and open-ended instructional tasks, such as those used in project-based, problem-based, and inquiry learning, that provide the students with affordances to reason (Barron, Schwartz, Vye, & Moore, 1998; Chinn & Malhotra, 2001; Duschl, 2000; Haskill, 2001, Hammer & Elby, 2002; Magnusson, & Palinscar, 1995; Penner, Lehrer, & Schauble, 1998). More generally, fostering a culture of communication in which children are encouraged to talk to one another, argue about ideas, explain concepts, and share their discoveries supports the development of reasoning (Bruner, 1996; Polman & Pea, 2001; Roth, 2005).

RECIPROCAL TEACHING

Reciprocal teaching is one of the methods that are used to teach comprehension-fostering strategies to students. Reading scores have usually improved as a result of this instruction.

Until the 1980s, students were seldom provided with any help in reading comprehension. In a class study, Durkin (1979) observed 4,469 minutes of reading instruction in grade 4 and found that only 20 minutes of this time were spent in teaching students how to comprehend what they were reading. Durkin found that teachers spent almost all of the instructional time asking students questions, but they spent little time teaching students comprehension strategies they could use to answer the questions. Duffy, Lanier, and Roehler noted a similar lack of comprehension instruction in elementary classrooms: “There is little evidence of instruction of any kind . . . Seldom does one observe teaching in which a teacher presents a skill, a strategy, or a process to pupils, shows them how to do it, provides assistance as they initiate attempts to perform the task and assures that they can be successful” (1980, p. 514). As a result of these astonishing findings, investigators developed and taught students to use specific cognitive strategies that were designed to help them perform higher-level operations in reading. Palincsar and Brown (1984) referred to these strategies as “comprehension-fostering” activities.

Teaching students to ask questions about the material they are reading is an example of a comprehension-fostering activity. Asking questions, by itself, does not directly lead in a step-by-step manner to comprehension. Rather, in the process of generating questions, students need to search the text and combine information, and these processes serve to help students comprehend what they read. A cognitive strategy, then, is a guide or a scaffold that serves to support the learners as they develop the internal procedures that enable them to perform the higher level operations.

TWO MAJOR COGNITIVE STRATEGIES

Two of the major and most researched cognitive strategies have been teaching students to ask questions about material they were reading and teaching students to summarize passages.

The cognitive strategy of asking questions was usually taught by providing students with a list of signal words who, what, when, why, how that students could use to form questions. The strategy of summarizing was frequently taught using a *legs and table* procedure in which students first list the major details (the legs) and then use the legs to compose a summary sentence (the table).

TEACHING COGNITIVE STRATEGIES

In many of these studies the cognitive strategies were taught directly by the teacher. The teacher first presented a list of signal words and then modeled the use of these words to ask questions about the material in a story or a passage. Then the teacher guided the students as they began to generate questions about the material, and, finally, the students asked questions independently, without much supervision.

Students were taught to use the legs and table strategy the same way. First, the teacher modeled how to select the main points (the legs) and then use these points to develop a summary (the table). Then the teacher supervised the students as they practiced identifying the legs and the table. The teacher would guide the students as they practiced by first summarizing a paragraph, then several paragraphs, then a passage, and then a larger unit. Finally, the students worked on their own, with minimal supervision from the teacher.

Reciprocal teaching, a term and practice developed by Palincsar and Brown (1984), is a variation on the traditional teaching method. In reciprocal teaching the focus is also upon teaching students specific comprehension-fostering strategies. Palincsar and Brown taught students four strategies: asking questions about the text, summarizing what was read, predicting what might happen next, and attempting to clarify words and phrases that were not understood. But in reciprocal teaching, the practice of applying these strategies takes place primarily in the context of a dialogue between the teacher and the students.

In reciprocal teaching, students read a passage of expository material paragraph by paragraph. During the early stages of the lesson, the teacher assumes the major responsibility for instruction by explicitly modeling the process of using these strategies on a selected text. The students then practice the strategies on the next section of text and the teacher supports each student’s participation through specific feedback, additional modeling, coaching, hints, and explanations. The teacher adjusts the difficulty of the task according to the current level of the student. As Palincsar and Brown (1984) explained:

The teacher models and explains, relinquishing part of the task to novices only at the level each one is capable of negotiating at any one time.

Increasingly, as the novice becomes more competent, the teacher increases her demands, requiring participation at a slightly more challenging level. (p. 13)

During this guided practice the teacher invites students to initiate discussion and to react to other students' statements. Student participation can include (a) elaborating or commenting on another student's summary, (b) suggesting other questions, (c) commenting on another's predictions, (d) requesting clarification of material not understood, and (e) helping to resolve misunderstandings.

The teacher supports the students by rephrasing or elaborating on their answers, comments, or questions, and by providing hints and instruction when needed. In the course of this guided practice, there is a gradual shift in responsibility from the teacher doing much of the work to the student taking over the major thinking while the teacher observes and helps only when needed.

At this point, the practice becomes a dialogue: one student asks questions, another answers, and a third comments on the answer; one student identifies a difficult word, and the other students help to infer the meaning and give reasons for the inferences they made. The emphasis throughout is on a cooperative effort by the teacher and students to bring meaning to the ideas in the text, rather than merely restating the words. In addition, during the dialogue, students are provided instruction in when, why, and where these activities should be applied to the text.

Reciprocal teaching, then, has two major features: instruction and practice of the four comprehension-fostering strategies and the use of the reciprocal teaching dialogue as a vehicle for learning and practicing these four strategies.

The process of gradual introduction of a skill by a teacher who provides assistance to students as they practice is similar to the guided practice described by Hunter (1982), Good and Grouws (1979), and Rosenshine and Stevens (1986). In reciprocal teaching, however, much greater emphasis is placed on encouraging students to provide instructional support for each other.

RESULTS

Two different types of tests were used to study the effect of using reciprocal teaching methods. Some investigators developed their own tests while other investigators used standardized tests in reading. Some investigators used both their own tests and standardized tests.

When experimenter-developed tests were used in the reciprocal teaching studies, the results were usually statistically significant and the average effect size was .88. An effect size of .88 means that students who scored at the 50th percentile in the experimental group would have

scored at the 88th percentile if they had been in the control group (Rosenhine & Meister, 1994). When standardized tests were used the average effect size was .32. This result means that on the standardized tests, students who scored at the 50th percentile in the experimental group would have scored at the 63rd percentile if they had been in the control group. An effect size of .88 is considered to be very large.

As noted, asking questions has also been taught in traditional settings, without the reciprocal teaching addition. When experimenter-developed tests were used in these studies the results were also usually statistically significant and the average effect size was .89. When standardized tests were used the average effect size was .34 (Rosenhine, Meister and Chapman, 1996). This result means that the same statistically significant results were obtained for teacher-led instruction when only the question-asking strategy was taught as were obtained using the reciprocal teaching format when four cognitive strategies were taught. These results suggest that the teaching of cognitive strategies is a useful instructional procedure for raising student achievement, and these strategies can be successfully taught in both a traditional and a reciprocal teaching format.

Palincsar and Brown (1984) suggest that what the students learned was not simply how to ask questions and summarize. Rather, the new strategies enabled and required the students to perform deeper processing of what they read, to engage in making sense of what they read, to be aware of what they did not understand the material, and to engage in additional searching when they encountered comprehension difficulties, and it was the learning and practice of these processes that led to the improved comprehension.

REINFORCEMENT

Reinforcement is an event that increases behavior. In the classroom, reinforcement occurs as teachers manage the environmental events that follow students' desired ways of behaving so to increase the strength and future likelihood of that behavior.

Reinforcement comes in two types: positive and negative. Positive reinforcement occurs when desired behavior is strengthened by the presentation of a contingent stimulus. The attractive, behavior-increasing, contingent stimulus used during positive reinforcement is referred to as a positive reinforcer. A positive reinforcer is defined as any environmental event that, when given in response to the behavior, increases the strength and frequency of that behavior. Some commonly used positive reinforcers in the classroom are praise, attention, tokens, and stickers.

Negative reinforcement occurs when desired behavior is strengthened by the removal of a contingent stimulus. The aversive, behavior-increasing, contingent stimulus that is removed during negative reinforcement is referred to as a negative reinforcer. A negative reinforcer is defined as any environmental event that, when taken away in response to the behavior, increases the strength and frequency of that behavior. Some commonly used negative reinforcers in the classroom are taking away an aversive assignment (e.g., homework), withdrawing an intrusive stare, or canceling a chore.

Table 1 provides a sample of reinforcers commonly used in K-12 classrooms. The left side of the table lists a variety of positive reinforcers that teachers give to strengthen students' behavior, while the right side of the table lists a variety of negative reinforcers that teachers take away to strengthen students' behavior. What is common to all positive reinforcers in the list is the idea that after the student engages in a particular behavior, he or she receives an attractive consequence for doing so.

Examples of positive and negative reinforcers commonly-used in K-12 classrooms

Positive reinforcers	Negative reinforcers
Giving praise	Taking away a deadline
Giving stickers	Taking away surveillance
Giving privileges	Taking away an unattractive assignment
Giving tokens	Taking away a threat
Giving attention	Removing a negative evaluation
Giving good grades	Removing bad grades
Giving scholarships	Taking away criticism
Giving an honor	Stopping one's ridicule
Giving a trophy	Stopping one's teasing
Giving a prize	Stopping one's yelling or screaming
Giving an award	Stopping one's crying
Giving food	Stopping one's whining
Giving money	Stopping one's staring
Giving a smile	Stopping one's pleading or pouting
Giving positive feedback	Stopping laughing (at someone)

Table 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

That is, when the student turns in her homework, the teacher then places a sticker on the paper. The sticker is given after the homework has been handed in and with the intention of strengthening the likelihood that future homework assignments will be forthcoming. What is common to all negative reinforcers in the list is the idea that when the student engages in a particular behavior, he or she gets a break from an unattractive or aversive consequence for doing so. That is, when the student turns in her homework, the teacher then exempts the student from an arduous assignment of long division problems. The arduous assignment is removed after the homework has been handed in and with the intention of strengthening the likelihood that future homework assignments will be forthcoming.

REINFORCERS AND REWARDS

Reinforcement is defined by its effect on behavior. Only environmental events that actually increase behavior are reinforcers. If an event such as a smile, candy bar, or break from chores does not increase the student's behavior, then the event is not actually a reinforcer. This qualification of which environmental events are reinforcers and which are not is an important point because teachers often implement consequences haphazardly (non-contingently) or inconsistently (Kauffman, 1996; Pullen, 2004). Praise represents a good example of commonly used attractive environmental event that is used for a dozen different reasons, only one of which is to reinforce (increase) students' behavior (Brophy, 1981). Further, teachers do not reinforce positive behavior as

Reinforcement

often as they could (Wehby, Symons, Canale, & Go, 1998). Instead of delivering contingent and strategic consequences for desired behavior (i.e., reinforcers), what teachers more typically offer to students are promises of reward.

A reward is the offering of an environmental event in exchange for the student's participation, service, or achievement (Craighead, Kazdin, & Mahoney, 1981). When a teacher promises an award if the student will complete an assignment or when a teacher promises a prize to acknowledge a successful performance, she introduces a reward into the learning environment. Adding a discussion of rewards to a discussion of reinforcement highlights the instructional practice of soliciting students' behavior or acknowledging their achievement, regardless of whether those rewards actually reinforce behavior. The discrepancy between reinforcers and rewards is that a reward functions as a reinforcer only when the student values it enough to affect a change in his or her behavior. Sometimes teachers use rewards that students do not value (e.g., public recognition), and unappealing rewards do not increase the frequency of the desired behavior. If the student is embarrassed, rather than gratified by, the public recognition then it will not reinforce (i.e., strengthen) the behavior, and it might even act as a punisher to some students. The important point is that teachers offer rewards in hopes of soliciting behavior, while they deliver contingent reinforcers to increase desired behavior which has already occurred.

ASSUMPTIONS THAT RELATE REINFORCEMENT TO LEARNING

Reinforcement is an educational concept rooted in behavioral learning theory (Baldwin & Baldwin, 1986). Behavioral learning theory does not focus on mental knowledge, such as learning information. Neither does it focus on cognitive and sociocultural concepts, such as creating meaning, understanding concepts, using memory, and the experience of conceptual change. Instead, behavioral learning theory focuses on behavior. Specifically, it focuses on voluntary, intentional, and situationally appropriate behavior. So, the learning highlighted by behavioral learning theory is learning how to adapt successfully to one's environment (e.g., raise one's hand before speaking, wait one's turn in the lunch line). Reinforcers play the important role they do in helping students learn how to adapt to the classroom (and school) environment by signaling which behaviors are desirable (those that are reinforced) and which are not (those that are not reinforced). Students learn which behaviors are desirable and adaptive by learning which behaviors are associated with reinforcers. The assumption that relates reinforcement to learning is that the presence of a rein-

forcer signals that a particular behavior is desirable, and this signaling process, therefore, helps students learn how to adapt more successfully to the classroom environment.

ASSUMPTIONS THAT RELATE REINFORCEMENT TO MOTIVATION

Reinforcing students' desirable behaviors with positive and negative contingencies is an extrinsic motivational strategy. Motivation researchers outside behavioral learning theory find that extrinsic rewards often undermine students' intrinsic motivation and capacity for autonomous self-regulation (Deci & Ryan, 1985; Deci, Koestner, & Ryan, 1999; Kohn, 1993). That is, reinforcers and rewards produce complicated, and often undesirable, motivational side-effects. The undermining effect that extrinsic rewards often have on intrinsic motivation and autonomous self-regulation is important for two reasons. First, many teachers incorrectly assume that adding extrinsic rewards on top of students' intrinsic motivation will create a supermotivation in which the two types of motivation (extrinsic and intrinsic) will combine and complement one another. Instead, extrinsic rewards typically interfere with and undermine intrinsic motivation and autonomous self-regulation. Second, teachers often offer students extrinsic rewards when introducing uninteresting activities in the hope that the reward will be able to generate the motivation to engage in the task that the task itself cannot generate (because it is uninteresting). From a motivational point of view, teachers therefore use positive reinforcers, negative reinforcers, and extrinsic rewards to bolster students' otherwise low motivation (Boggiano, Barrett, Weiher, McClelland, & Lusk, 1987). In doing so, teachers are essentially trying to set up (manage) conditions that make desired target behaviors, such as engaging in uninteresting (but educationally important) lessons, more likely.

CLASSROOM MANAGEMENT TO PROMOTE EDUCATIONAL OUTCOMES

Many positive educational outcomes can be framed in terms of desirable behavior. Teachers, administrators, and parents all consider behaviors such as attending school regularly and promptly, being actively engaged during classroom lessons, showing respect for others, making good grades, and graduating from school as desirable ways to behave. Because educators value these ways of behaving and because they would like to see students engage in these ways of behaving more frequently, they find merit in classroom management practices, the most popular and the most effective of which involves the strategic use of positive reinforcers, negative reinforcers, and extrinsic rewards (Landrum & Kauffman, 2006).

The fundamental task of classroom management is to create a caring, supportive, inclusive, and engaging

community in which students frequently engage in desirable, constructive, and prosocial behavior (Weinstein, Curran, & Tomlinson-Clarke, 2003). When practiced effectively, classroom management is a proactive strategy that creates a classroom environment in which desirable behavior is expected, supported, and reinforced. From this point of view, reinforcement plays only one part in the teacher's larger effect to manage the classrooms. In addition to reinforcing desirable behavior after it occurs and in addition to offering extrinsic rewards to solicit students' desired behavior, teachers can further support students' desirable ways of behaving by adding additional classroom management strategies such as modeling and observational learning (Ozur & Bandura, 1990), scaffolding and tutoring (Chi, Siler, Jeong, Yamauchi, & Jausmann, 2001), behavioral supports (Casteel, Isom, & Jordan, 2000), and promoting students' effective self-management (Bohn, Roehrig, & Pressley, 2004).

RELEVANCE OF SELF-EVALUATIONS TO CLASSROOM LEARNING

There has been controversy in the psychological and educational literature about the role of self-concept and global self-esteem in the classroom. How are these constructs best defined, and distinguished from each other, as well as from self-efficacy? Is an understanding of students' perceptions of their scholastic ability related to their motivation to perform in the classroom room? How does the accuracy of students' perceptions of their academic performance impact their preference for intellectual challenge? What are the implications for educators, in terms of possible interventions in the classroom? Here there is also controversy. Should educators focus on the enhancement of scholastic skills themselves or should attention be directed toward impacting self-concept as the primary target? How is global self-esteem relevant to students in the classroom, as well as to interventions?

DEFINITIONAL ISSUES

Before addressing these substantive issues, it is important to untangle the often confusing terminology. For example, among the many terms are *self-concept*, *self-efficacy*, and *self-esteem*, to name three that are a source of confusion. The definitions offered here are those that appear to be the most useful, in terms of clarity. Self-concept refers to one's perceptions of competence or adequacy across specific domains, for example, scholastic competence, athletic competence, and social competence, as well as feelings of adequacy in such domains as perceptions of appearance and the evaluations of one's behavioral conduct or morality (see Harter, 1999). Thus, the concept of domain-specific self-concepts is particularly

useful in discriminating differences between the various arenas in which one has self-perceptions of competence and/or adequacy.

This approach is particularly useful in identifying a profile of self-perceptions across the various domains that are included on any given instrument adopting this framework. That is, the vast majority of children and adolescents do not feel equally competent and/or adequate in every domain assessed. Their scores on domain-specific measures vary across domains, leading to different profiles for individuals. Summing or averaging such scores can mask the incredible differences that individuals report across domains. From an educator's perspective, perceptions of competence in the domain of scholastics may be particularly critical to discriminate from other domains, although the latter may also be of interest.

Another term that represents a source of confusion is self-efficacy, a construct identified by Bandura (1977). Self-efficacy refers to the belief that one can or will be efficacious in a particular arena. It has a futuristic connotation. For example, a student may feel that "when I am faced with new academic challenges, I will be successful." Domain-specific self-concept, in contrast, refers to self-evaluations in the present, for example, "I am very good at my schoolwork (right now)." While the two constructs, self-concept and self-efficacy, may be correlated with one another, they are not the same and therefore there can be discrepancies between the two. For example, students could feel competent in the present about their specific ability, if facing new challenges, associated with movement to a new grade, a new teacher, a new school, but not necessarily possess self-efficacy about their future ability to perform. Conversely, students may feel that they can be efficacious in the future, if a change favors their abilities, but may not experience domain-specific competence in their present educational environment. (In this entry, the focus will be on domain-specific competence, emphasizing the scholastic or academic domain, and will not address self-efficacy, although it is important to distinguish clearly between the two constructs.)

APPLICATIONS OF DOMAIN SPECIFIC SCHOLASTIC COMPETENCE

Before addressing the third construct, self-esteem, which is not domain-specific but rather an overall evaluation of one's worth as a person, two classroom applications of domain-specific scholastic competence will be considered: (a) how perceptions of scholastic competence impact intrinsic versus extrinsic motivation in the classroom, and (b) whether the accuracy of perceptions of scholastic competence is predictive of preference for scholastic challenge, one motivational component.

An important motivational dimension critical to educators is whether children are *intrinsically* or *extrinsically* motivated in the classroom. Three dimensions of motivation have been identified (Harter, 1981): First, are the students intrinsically motivated by curiosity and the love of learning or are they merely extrinsically motivated to do the schoolwork assigned? Second do the students prefer academic challenge or do they merely want easy work that they are sure they can accomplish? Third, do the students prefer to approach schoolwork independently or are they dependent on the teacher and need help and/or to be given the correct answer? These dimensions are highly correlated with one another and thus can be combined into a single score representing a student's average motivation along a dimension from intrinsic (highest score = 4) to extrinsic (lowest score = 1).

There is considerable variability in students' motivational level, across grade levels as well as within a given grade level. Developmentally, across grades 3 through 9, there is a systematic decline representing a gradual shift from intrinsic motivation in the third grade to extrinsic motivation during adolescence (Harter, 1981). Eccles, Midgley, and Adler (1984) have suggested that grade-related changes in educational practices are responsible. A focus on academic grades and test performance, including public posting of scores, social comparison, a shift from an emphasis on effort to ability, ability grouping, and a shift from an emphasis on the product of one's performance to the process of learning could all adaptively contribute to a decline in intrinsic motivation and an increase in extrinsic motivation.

Not all students show this unilateral shift. A longitudinal study by Riddle and Harter (reported in Harter, 1990) studied motivational patterns in children making the transition from a sixth grade elementary school to a middle school (seventh and eighth grades). Some showed the decline to extrinsic motivation over this transition, some reported no change, and yet a third group actually showed increases toward greater intrinsic motivation.

What might explain these three different patterns? The researchers found that the patterns were directly predicted by students' perceived scholastic competence. Students whose perceived scholastic competence increased across the transition from sixth to seventh grades, reported a shift toward greater intrinsic motivation, those reporting no changes in scholastic competence reported no changes in level of motivation, and those reporting a decrease in perceived scholastic competence reported a shift to more extrinsic motivation.

Why should children's perceived scholastic competence change as a function of the transition to a new school? In this study, students from three elementary feeder schools made the shift to one junior high school.

This means that two-thirds of the students were undoubtedly new to each individual. Social comparison processes would lead to the conclusion that the hierarchy of perceived competence would shift for many, leading to different perceptions of their perceived scholastic competence (see Harter, 1996). These, in turn, impacted the level of intrinsic vs. extrinsic motivation. Thus, the more students feel scholastically competent, the more they will be drawn to an intrinsic motivational orientation. Conversely, if students report a decline in scholastic competence, they will shift toward an extrinsic motivational style in which they may feel more assured of some success and less failure.

The second application of domain-specific competence concerns the accuracy of perceptions of scholastic competence and preference for challenge. Do the accuracy of self-perceptions have an impact? In one study of the component of preference for challenge, the researchers first established accuracy by comparing teachers' ratings of students' scholastic competence to the students' own perceptions of scholastic competence. Students were divided into "over-raters," those whose scores significantly exceeded the rating of the teacher, "under-raters," those whose scores were significantly lower than the teacher's ratings, and "accurate" raters, those whose scores were congruent with the teachers' (see Harter, 1999).

Next, students were brought into a university classroom in which research assistants acted as teachers. Students were given a booklet that contained anagrams of different levels of challenge, three-letter to seven-letter anagrams, to be unscrambled to make legitimate words. They were given a choice of which they wanted to attempt (see Harter, 1999, for details). Results revealed that the under-raters selected the easier anagrams, presumably because they did not feel scholastically competent. Surprisingly, perhaps, the over-raters who reported high perceived scholastic competence also selected the easiest anagrams. Accurate raters chose the most challenging anagrams.

Why should those reporting high levels of perceived competence select easier anagrams? It should be recalled that this group, the over-raters, were so designated because teachers were not in agreement with their perceptions, viewing them as less competent than the students themselves. The researchers interpreted these findings to reflect the fact that these over-raters, at some level, consciously or perhaps defensively, knew that they were not as competent as their ratings implied. Thus, rather than risk failure, they selected the easiest anagrams. This is an important finding because if over-raters select easier tasks in a simulated classroom, they are likely to select easier tasks in other arenas of their life. By avoiding challenges, they will limit their learning ability. Thus, it is not only the level of perceived scholastic competence that is relevant to the

prediction of certain forms of motivation but the accuracy of those judgments. The issue of why unrealistic evaluations can ultimately be psychologically debilitating will be further discussed below.

SELF ESTEEM

Another term that is critical to define is self-esteem. Self-esteem, in this entry, refers to a *global* perception of one's overall worth as a person, such as "liking who one is as a person," "being satisfied, overall with who one is." (Negative content is also included.) It should be noted that in the framework of Harter (1999) and Rosenberg (1979) global self-esteem is *not* the sum or average of domain-specific scores. It is its own construct, assessed by its own set of items.

From a developmental perspective, the ability to construct a global view of one's esteem does not appear until about age 8. Younger children (ages 4 to 7) do not have the cognitive skills to integrate information about the self into an overall self-evaluation of their worth (see Harter, 1985, 1999). Rather, they can only make judgments about domain-specific self-concepts such as cognitive competence, social acceptance, and physical competence. This does not mean that young children do not have some sense of their overall worth. Rather, they do not have a verbalizable concept of their global self-esteem, as a cognitive construct that can be expressed through language. However, it has been demonstrated that young children exude or manifest a sense of self-esteem in their *behavior*.

An empirical effort to identify the relevant behaviors by Haltiwanter and Harter has been described in Harter (1985). The researchers first asked teachers to sort behavioral descriptors into groups, those describing high- and low-self-esteem children, ages 4 to 7. Those defining the high self-esteem child included curiosity, exploration, pride in their "work" (e.g., drawings), and confidence, to name the primary descriptors. Those identified with low self-esteem displayed the lack of these attributes. Agreement among teachers was extremely high. The researchers then cast these items in a behavioral rating scale such that teachers or relevant adults could evaluate children on a four-point scale in which they rated each item separately. These could then be averaged to arrive at a score that represented young children's behaviorally manifest self-esteem.

To return to older children and adolescents, separate self-report measures of both domain-specific self-concepts and global self-esteem are needed because global self-esteem is highly related to depression, which, in turn, is predictive of suicidal thinking and behavior (Harter, 1999). These are major mental health concerns, particularly in contemporary society. In fact, reports indicate that

depression and suicide are on the rise among preadolescents, adolescents, and young adults. Thus, it is important to understand the causes of depression and suicide, namely lack of global self-esteem, as well as to understand the causes of different levels of global self-esteem. Often these factors are difficult for teachers to observe, and observing them is not the primary task of the educator. Thus, self-report measures that may be administered by school counselors, social workers, or mental health professionals, can aid in the identification of children at risk.

In understanding the causes of global self-esteem and the relevance of domain-specific self-concepts, it is critical to assess domain-specific self-concepts because they can contribute to global self-esteem, as was pointed out by an historical scholar of the self, William James (1842–1910) (1892). James argued that global self-esteem was the product of those domain-specific successes that individuals viewed as particularly important to their well-being (see Harter, 1985, 1999). For example, if scholastic competence is important to students and they are doing well academically, that may be one contributor to high global self-esteem. Conversely, if scholastic competence is important but the students are doing poorly at schoolwork, then they will experience low global self-esteem. The same logic applies to other domains. An example involves the domain of perceived physical attractiveness. In fact, this domain bears the highest correlation with global self-esteem (see Harter, 1985; 1999). The correlation between scholastic competence and self-esteem is the second highest correlation. Thus, to understand one's level of global self-esteem, it is critical to examine domain-specific self-concepts and the relationship they bear to how much one likes oneself as a person, overall.

Another influential theory of the causes of global self-esteem was put forth by Charles Horton Cooley (1864–1929) (1902), another historical scholar of the self. Unlike James, Cooley contended that the opinions of significant others were the key to understanding one's level of self-esteem. Cooley proposed the metaphor of the "looking glass self." Other people are social mirrors into which individuals psychologically gaze in order to divine how they are being perceived. If people feel that others hold them in esteem and approve of them as worthy individuals, then they will incorporate their view into their self-evaluation of their own overall self-esteem. Conversely, if they feel that significant others do not value them, they will report low self-esteem.

Harter (1985, 1999) consistently discovered that approval from classmates is the best predictor of global self-esteem. Classmates are the public significant others who can scrutinize the self and whose resulting opinions are critical to one's self-esteem. The opinions of classmates, expressed directly (e.g., through comments that

may communicate negative evaluations of the self) or more indirectly (e.g., avoidance, conveying social rejection), are internalized in the form of low self-esteem. In contrast, the perceived positive acceptance by classmates will lead to positive acceptance of the self, in the form of high self-esteem. Thus, processes that occur within the classroom, namely, perceptions of domain-specific scholastic competence and perceptions of classmate approval are each critical to global self-esteem.

IMPLICATIONS FOR INTERVENTION

A comprehensive coverage of the implications for intervention can be found in Harter (1999). A few of these principles will be summarized here. One issue is whether the goal of interventions should be the enhancement of domain-specific self-evaluations, for example, scholastic competence, or efforts to promote the accuracy of self-evaluations. Some scholars advocate enhancement as the primary goal, such that students will feel good about themselves. However, others point to the dangers of promoting unrealistically high domain-specific evaluations and urge that interventions promote more realistic self-perceptions. The negative effects of over-rating one's scholastic competence were described above.

A similar controversy applies to the construct of global self-esteem. While "feel-good" approaches aimed at encouraging students to value themselves as individuals may give students a temporary psychological lift, in the long run they can have detrimental effects. Damon (1995) views such efforts as misguided, in that they lead to an inflated sense of self-esteem. He argues that they divert educators from teaching skills and deprive students the thrill of actual accomplishment. Damon contends that the importance of self-esteem as a commodity has been greatly exaggerated and that the effusive praise that parents or teachers heap on children to make them feel good is often met with suspicion by children. Moreover, it interferes with the goal of building specific skills in the service of genuine achievement.

Other strategies apply to interventions to influence social self-evaluations. For those reporting low social support from parents, one should determine whether they are withholding support because their children are not meeting parents' highly demanding and often unrealistic expectations. Encouraging parents to accept their children for who they are and for domains in which the child has talents is one goal. For example, parents of a child who has legitimate academic limitations (low intelligence, learning disabilities) but who is musically talented should reward musical accomplishments rather than critically hound the child for lack of academic success. If these strategies are unworkable, then providing some type of compensatory support, in the form of a

special adult who can provide support, for example, an extended family member or those in programs like Big Sisters and Big Brothers.

Other students may lack peer support, contributing to low self-esteem. To the extent that they are realistic, attempts should focus on understanding the particular causes of their lack of acceptance. Do such children lack attributes that are valued by peers, for example, attractiveness, athletic ability, or interpersonal qualities that make them likable? Intervention efforts may be directed toward improving the child's skills in the relevant area(s), realizing that there will be natural limits on the extent to which the child may be able to improve. Another strategy may involve removing such children from an unsupportive peer-group situation and placing them with individuals who are likely to provide more support. Social skills programs may also be an option. Increasing social support from either parents or peers, in turn, enhance children's global self-esteem.

The present entry has focused on two critical constructs, students' domain-specific self-concepts and global self-esteem, and how they are relevant to the classroom. Research by Harter has revealed that students' motivation shifts from intrinsic to extrinsic motivation as a function of grade-level. Moreover, students' perceived scholastic competence is a powerful predictor of the level of intrinsic versus extrinsic motivation. In addition, Harter's research has demonstrated that those who over-rate and under-rate their scholastic competence are more likely to report low preference for challenge, which in turn can hamper efforts to approach challenging situations in the classroom as well as in other arenas of their life that can provide learning experiences.

RELIABILITY

Reliability is the consistency of a measure. In educational testing, reliability refers to the confidence that the test score will be the same across repeated administrations of the test. There is a close relation between the construct of reliability and the construct of validity. Many sources discuss how a test can have reliability without validity and that a test cannot have validity without reliability. In the theoretical sense, these statements are true but not in any practical sense. A test is designed to be reliable and valid, consistent, and accurate. Practical conceptualizations of reliability cannot be discussed separately from examples with validity.

RELIABILITY AND VALIDITY

Reliability without validity would be similar to an archer consistently hitting the target in the same place but missing the bull's eye by a foot. The archer's aim is reliable because it is predictable but it is not accurate. The archer's aim never hits what it is expected to hit. In this analogy, validity without reliability would be the arrows hitting the target in a haphazard manner but close to the bull's eye and centering around the bull's eye. In this second example, it can be seen that the validity is evidence that the archer is aiming at the right place. However, it also demonstrates that, even though the reliability is low, there is still some degree of reliability. That is, at least the arrows are consistently hitting the target. In addition, if the arrows are centered around the bull's eye, the error of one aim leading too far to the right is balanced by another aim leading too far to the left. Looking at the unpainted backside of the target's canvas, someone would be able to identify where the bull's eye was by averaging the distance of all the shots from the bull's eye.

Reliability of a test is an important selling point for publishers of standardized test, especially in high-stakes testing. If an institute asserts that its instrument can

identify children who qualify for a special education program, the users of that test would hope that it has a high reliability. Otherwise, some children requiring the special education may not be identified, whereas others who do not require the special education may be unnecessarily assigned to the special education program.

Even in situations perceived as low-stakes testing, such as classroom testing, reliability and validity are serious concerns. Classroom teachers are concerned that the tests they administer are truly reflective of their students' abilities. If a teacher administered a test that was reliable but not valid, it would not have much practical use. An example would be a teacher in a grade-school history class administering, as a midterm exam, a standardized test from a reputable publisher. If that exam was suggested by the test developer as the final exam, the results would most likely be reliable but not valid. The test results would be reliable because they would most likely reflect the students' rank order in class performance. However, the test would not be valid as most students would not be ready for half of the material being tested. If the grade-school history teacher administered as a midterm exam a standardized test recommended by the test developer as a midterm exam for the appropriate grade level, the test could be considered valid. However, if the students (for some strange reason) did not receive uniform instruction in grade-appropriate history, the test would most likely not be reliable.

From these examples, it is clear that it is easier to increase the validity of a reliable measure than to increase the reliability of an otherwise valid measure. The reliable archer could be trained, little by little, to move the aim in the direction of the bull's eye. However, the target could be moved over one foot, so that the bull's eye is at the spot on the target that the archer usually hits. The teacher could take the time necessary (half a school year) to teach the students what they need to know to pass the valid final exam. (This is similar to training the archer to shoot in the right direction.) Another solution for the classroom situation would be for the teacher to adapt the test items in the exam, so that it is more appropriate as a midterm exam, instead of as a final exam. (This is similar to moving the target so that the archer's aim hits the bull's eye.)

In the test publishing world, the reliability of a draft test instrument is often quickly established. However, after the test is used many times, its validity might be questioned. A test designed as a verbal reasoning test may rely heavily on the test-taker's knowledge of music, art, and history. Because the test is reliable, the publishers might redefine what construct it is measuring; in this case, it is a better measure of the students' knowledge of the humanities than of verbal reasoning. The publisher would recall all copies of the Verbal Reasoning test; then,

with little change to the test, the publisher could offer it again as the Humanities Achievement test.

Test reliability is explained through the true score theory and the theory of reliability. True score theory states that the observed score on a test is the result of a true score plus some error in measurement. The theory of reliability compares the reliability of a test of human characteristics with the reliability of measuring instruments in the physical sciences.

RELIABILITY IN TRUE SCORE THEORY

True score is the exact measure of the test taker's true ability in the area being tested. With a perfect test, the observed score would be equal to the true score. However, there is no perfect test. As one example of where the error may occur, the wording of test items may not be detailed enough for some test takers yet be too detailed for others. The examples of test errors are innumerable. According to true score theory, no one can know what the reliability of the test is unless one knows how much random error exists in the test. One cannot know how much error exists in the test unless one knows what the true score is. As a theoretical concept, the true score cannot be known. Therefore, what the reliability is can never be known with certainty. However, one can still estimate what the reliability is through repeated measures. As the error is assumed to be random, it should be balanced out over many administrations of the same test. If the test-taker's ability measured by the test is unchanging, when the error inflates the observed score one time it can be expected to deflate the observed score to the same degree at another time.

THE THEORY OF RELIABILITY

According to the theory of reliability, when a test is administered to a group of individuals, the observed variance in the distribution of scores should be due only to the true variance in the ability levels of the test takers. The degree that the two variances match is the reliability evaluation.

Another principle of the theory of reliability is that the reliability of a test is the ratio of the true score over the observed score. This relates to the true score theory because if the true score equals the observed score, then the error term must equal zero and the ratio of the true score to the observed score will be a perfect 1. Any deviation from this perfect ratio is caused by the strength of the error term (whether a positive or negative value). Therefore, expressing reliability as the ratio of the true score to observed score is in agreement with true score theory.

Reliability can also be expressed as the ratio of the variance of the true score to the variance of the observed score. Still, as noted above, one cannot know what the true score is, so one cannot know what the variance of the true

score is. One way to estimate the variance of the true score is to calculate the covariance of two observed scores from the same test with the same test takers with unchanging ability.

The covariance of two measures is the variance that the two measures share. It is the numerator in the calculation of the correlation of the two measures. The denominator of the correlation is the standard deviation of one measure times the standard deviation of the second. Because the measures are assumed to be the same, their standard deviations should be the same. Therefore, the product of the two standard deviations should equal the square of the standard deviation of the one measure. Statistically, this is the same as the variance of the observed score. The conclusion is that the estimation of reliability is the same as the correlation of two distributions of matching scores from the same test.

In summary, according to reliability theory, reliability is equal to the ratio of the variance of the true score to the variance of the observed score. Calculating the ratio of the estimated variance of the true score to the variance of the observed score is the same as calculating the correlation between two observed scores. Therefore, the correlation of two repeated measures of the same test is accepted as an appropriate estimate of the reliability of the test.

TYPES OF RELIABILITY

Inter-rater (or inter-observer) reliability is an important consideration in the social sciences because there are many conditions for which the best means of measurement is the report of trained observers. Some classes such as gymnastics can only be assessed through the ratings of expert judges. As another example, external observers may be brought into a classroom to assess a student's inappropriate behavior. The observations of only one observer can be challenged from so many points of view. A lone observer may have some personal expectancies of what is supposed to occur. The lone observer may get tired and bored, so that earlier observations are more precise than later ones. It is less likely that the reports of two or more observers would be challenged. Particularly, the acceptability of the reports of two or more observers increases when their observations are similar. The measure of the similarities of the observations coming from two or more sources is the inter-rater reliability.

One method to establish inter-rater reliability is to calculate the proportion of agreement between or among the observers. This is appropriate if the ratings or observations are in mutually exclusive categories. The two observers recording the behavior of the student with the

inappropriate behavior would do well to have a common checklist of the likely behaviors. If they agree on the occurrence of 16 out of 20 behaviors, their inter-rater reliability would be 80 percent.

Another method is to calculate the correlation between the ratings of the two or more observers. This is possible if the ratings or observations are two or more sets of interval numbers. The gymnastic judges would have different ratings. Some may be consistently rating high while others consistently rating low. However, there should be some general agreement on the ranking of the different performers. The strength of this agreement would be reflected in the correlation of their ratings.

Inter-rater reliability is increased if the observers have appropriate training. The training should focus on what exactly is meant to be observed. The raters need to be given a clear description of the event to be observed. The classroom observers would need to know what is and is not appropriate behavior. The raters also need concrete examples of what constitutes an occurrence or what constitutes achievement at each criterion level. The gymnastic judges need to know the standards for each element of the gymnastic routine. Training is best when it includes much practice with feedback.

Test-retest reliability is appropriate for tests that measure a construct that is not likely to change. The construct that intelligence tests measure is not expected to change. Another well-known test with an expectedly unchanging construct is the Scholastic Aptitude Test (SAT). Although a test taker is allowed to take the SAT up to three times, the developers claim that the score on repeated administrations will not change. The construct that the SAT is measuring is the predicted adaptability to college. By the time students take the SAT, they are as prepared for college as they are going to be.

Test-retest reliability is described as the correlation between the distribution of scores on one administration and the distribution of scores on a subsequent administration. Test-retest reliability is also an important factor in some experimental designs in which the treatment group is administered a pretest and posttest with treatment in between and the control group only receives the pretest and the posttest. Any analysis of the difference noted in the results of the posttest (compared to the pretest) of the treatment group is confounded unless there is a strong reliability between the pretest and posttest of the control group.

Parallel-forms reliability evaluates the consistency of the results of two tests constructed in the same manner from the same content domain. For every item on the test, a similar item is developed with the same difficulty level. The items from each pair are then randomly assigned to one form of the test or the other. The resulting two tests

are the same in content and difficulty but not expression. The reliability is described as the correlation of the two distributions of scores. This type of reliability is important in the development of standardized tests.

Split half reliability is similar to parallel forms except that the two forms are both incorporated into one test. After the test is administered, the scores are divided into the two forms and the correlation between the two distributions of scores is calculated. Like parallel forms it is important in the development of standardized tests. However, it could have classroom applications if the classroom teacher was willing to make the effort to develop a test with twice as many items as an ordinary test. In the classroom, split-half reliability could detect the effect of students' guessing on the test.

Inter-item reliability is another means of evaluating the reliability of one administration of one test. Most tests are made up of items that are related to one another because they are measuring similar concepts. Because the items are similar in design, there should be a measurable correlation between the items in any pair of items. The evaluation of inter-item reliability begins with predicting all correlations between all pairs of items. The inter-item reliability is expressed as the proportion of correct predictions. A classroom teacher might want to use inter-item reliability to identify the items that were not related to any other items or to identify the effects of students' guessing.

Cronbach's Alpha and the Kuder-Richardson methods are systems of reporting internal consistency of a test. The essential results of the internal consistency methods are comparable to the average of all correlations between all pairs of items. These methods can estimate reliability using the results of only one administration of the test. The main difference between the two approaches is how the items are scored. Cronbach's Alpha can be used on items with a range of responses such as a Likert scale. The Kuder-Richardson methods require that all items be scored dichotomously right or wrong (Borg and Gall, 1983).

PROCEDURES TO INCREASE RELIABILITY

The general goal to increase reliability of a measure is to increase the variance while reducing the variance error. Three recommended procedures to accomplish this are: 1) decrease the ambiguity of the test items; 2) increase the number of items per objective; and 3) provide clear test-taking instructions (Kerlinger, 1986).

If an item is ambiguous, it can be interpreted in more than one way. Two test takers of equal ability could conceivably interpret an ambiguous item two different ways, one getting it right and the other getting it wrong.

Their score would differ based on their interpretation of the item and not based on their differences in true ability.

Where there is error in a test item, it will have less effect if that item is one among many for the same objective than if that item is one among few. A test taker whose ability is mismeasured by a faulty item will need to balance the effect of that item with the effect of the items that are measuring more accurately.

Clear test-taking instructions help test takers to interpret the test items correctly and to indicate their chosen answers properly. Test instructions might remind the test takers of the types of items that require special attention. In addition, if there is a special procedure for answering such as using an answering sheet, test instructions can remind test takers how to respond correctly.

RESEARCH METHODS: AN OVERVIEW

There are many different methodologies that can be used to conduct educational research. The type of methodology selected by a researcher emanates directly from the research question that is being asked. In addition, some of the differing techniques for conducting educational research reflect different paradigms in scientific thought. In this entry, a review of the most commonly used methodologies is presented; in addition, the strengths and weaknesses of various methods are compared and contrasted.

OVERVIEW OF RESEARCH METHODS IN EDUCATION

Research methodologies can be classified in many different ways. For example, some researchers distinguish between quantitative and qualitative studies; others distinguish between experimental and non-experimental research; still others distinguish between research that is

Examples of strengths and weaknesses of various research methodologies		
Methodology	Major strength	Major weakness
Correlational	Can be used to examine complex relations among many variables.	Can't draw conclusions about causality.
Experimental	Can draw conclusions about causality.	Often does not represent true learning environments in real classrooms.
Quasi-experimental	Can simulate an experiment in a true classroom setting.	More difficult to justify causal conclusions than in true experiments.
Qualitative	Can provide detailed, in-depth analyses of the contexts of learning environments.	Very time-consuming, both in terms of data collection and analysis.
Longitudinal	Can examine changes in variables over time.	Very costly, and subjects may drop out over the course of the study.
Cross-sectional	Efficient and rapid way to examine developmental differences.	Not nearly as accurate as longitudinal designs; cohorts may differ, and these differences may be mistaken for true developmental differences.
Design experiments	Occur in actual classrooms; experiments are constantly altered based on actual occurrences in the classrooms.	Very time-consuming; sometimes quite difficult to examine causality.
Microgenetic research	Allows for in-depth analyses of development in strategy usage over time.	Very time consuming; often uses very small samples.
Single-subjects	Provides detailed data about changes in a specific variable in one individual learner at a time; can be particularly useful in developing interventions for learners with special needs.	Difficult to generalize to larger populations.
Action research	Involves real classroom teachers investigating questions that are directly important to practicing educators.	Often does not meet the stringent criteria of other designs, and results may not be acceptable to the scientific community.

Table 1 ILLUSTRATION BY GGS INFORMATION SERVICES. CENGAGE LEARNING, GALE.

conducted in laboratories versus in the field (i.e., in classrooms). Obviously, there are many ways to categorize research methods. However, there also is much overlap in such categorizations. For example, a “non-experimental” study can be either quantitative or qualitative; an experimental study can include some qualitative components. This entry does not attempt to classify these methodologies; rather, the various methods are first briefly described and then compared and contrasted.

Correlational Research. *Correlational research* involves quantitatively studying the relations between and among variables. One of the hallmarks of correlational research is that cause and effect relations cannot be determined.

Researchers who engage in correlational research do not manipulate variables; rather, they collect data on existing variables and examine relations between those variables. A number of different statistical techniques can be used to analyze correlational data. An example of a correlational research would be an examination of the statistical relations between middle school students’ standardized examination scores in mathematics, and the students’ demographic characteristics (e.g., gender, ethnicity, socioeconomic status, etc.).

Experimental Research. In an experiment, participants are randomly assigned to one of several treatments. One

of the most basic experimental designs involves random assignment to either an experimental group (which receives some kind of treatment), or a control group (which does not receive the treatment). If the differences in treatment between the experimental and the control group are tightly controlled, and if subsequent to the experiment there are measurable differences between the two groups that were not present before the experiment, then researchers often conclude that the experimental manipulation “caused” the differences to occur.

Many researchers and government agencies consider true experiments to represent the gold standard in research; however, it is extraordinarily difficult to conduct true experiments in actual educational settings (i.e., schools). The primary reason for this difficulty is the fact that students can rarely be randomly assigned to conditions or classrooms in school settings. It is also important to distinguish between small-scale experiments and larger-scale clinical trials. Small-scale experiments can occur in settings such as laboratories or classrooms, whereas larger-scale clinical trials often occur across many classrooms or schools.

An example of an experiment would be a study examining the effects of a video presentation on learning multiplication skills. Students in a classroom where all students are learning about multiplication could be randomly assigned to either watch a video that demonstrates

multiplication skills, or to watch another video (i.e., a video about how to make ice cream sundaes); the students would probably be asked to view the videos in a highly controlled environment, where the experimental and control conditions could be as similar as possible (except for the video presentation). If on a post-test the students who watched the multiplication video outperformed the other students, then a researcher could conclude that the video “caused” the improved performance.

Quasi-Experimental Research. In quasi-experimental studies, researchers do not randomly assign participants to groups (Cook & Campbell, 1979). Quasi-experimentation is used often in educational research, because it is often impossible and sometimes unethical to randomly assign students to settings.

In quasi-experimental studies, researchers attempt to control for differences between non-randomly assigned groups in a number of ways. Two of the most common methods include (a) matching, and (b) statistical control. The following example explains the concept. A researcher is interested in comparing the effects of a traditional third-grade reading curriculum with the effects of an enhanced version of the curriculum that includes extra homework assignments. If the two versions of the curricula are being administered in different classrooms, the researcher can try to “match” similar classrooms on certain variables. For example, the researcher might decide to match classrooms on years of experience of the teacher, wherein teachers with much experience (e.g., 20 or more years of teaching experience) might be paired, so that for each pair of highly experienced teachers, one is assigned to each condition.

In addition, the researcher can statistically control for variables that are related to the outcome. If the researcher knows that variables such as socioeconomic status and prior reading ability are related to reading achievement, then the researcher can statistically control for these variables, in order to better assess the unique effects of the new curriculum.

Qualitative Research. Qualitative research represents a broad framework for conducting educational studies. Whereas *quantitative* research focuses on measurable variations between and among variables, *qualitative* studies focus on holistic descriptions of learners and teachers in naturalistic settings.

Fraenkel and Wallen (1996) describe five general characteristics of qualitative research studies. These include:

1. Researchers collect their data in naturalistic settings (e.g., classrooms), by observing and participating in regular activities.

2. Data are collected via words or pictures (not via numerical or quantifiable indicators).
3. Processes (i.e., how individuals communicate with each other about a lesson) are as important as products (i.e., whether or not students obtain the correct answers to a problem).
4. Most qualitative researchers do not start out with specific hypotheses; rather, they use inductive methods to generate conclusions regarding their observations.
5. Qualitative researchers care about participants’ perceptions; investigators are likely to question participants in depth about their beliefs, attitudes, and thought processes.

A variety of methods can be used to conduct qualitative studies. For example, qualitative researchers can collect their data from direct observations, from analyses of video or audio recordings, from interviews, or from long-term ethnographic studies.

There are a variety of different ways of analyzing qualitative data. Generally, researchers carefully examine their data and discover themes that emerge from the data. Sometimes several researchers will analyze the same sources of data and then compare their conclusions and examine the extent to which they agree or disagree (inter-rater reliability); in other studies, one researcher will conduct all of the analyses, and will also critically examine how his or her own biases may affect interpretations. Software packages have been developed to assist qualitative researchers with data analysis. Two of the most commonly used packages are Envivo and NUDIST.

Longitudinal and Cross-sectional Research. Many research studies in education focus on developmental issues (i.e., how individuals change over time). For example, it is known that the reading strategies that young children use are different from the reading strategies adopted by older children (Pressley & Harris, 2006). There are several different methods that can be used to examine such developmental phenomena.

In a *longitudinal* study, researchers collect data on the same individuals over a number of different time periods or “waves.” Thus the same group of students might complete study assessments at the end of first grade, second grade, third grade, and fourth grade. Researchers can then examine changes in student data across those four years.

In a *cross-sectional* study, researchers collect data on individuals of differing ages or developmental levels, at the same time. Thus data are collected for many students, at one time interval only. For example, a researcher might give assessments to 200 first graders, 200 second graders,

200 third graders, and 200 fourth graders all at the same time. Then the researcher can compare the results of students in these four different grades and try to draw some conclusions about developmental differences.

Most researchers agree that when possible, longitudinal studies provide better developmental data than cross-sectional studies. The primary advantage of longitudinal studies is that the same individuals are assessed at different time points; therefore, it is easier to make inferences about true development over time, since the distinct data points represent the same individuals across different time periods. However, longitudinal research is often difficult to conduct, because it is very expensive, and it is often difficult to track individuals over time; many of the students who participate in the first wave of data collection may have moved or may not want to participate in later waves of the study.

Design Experiments. When researchers conduct design experiments, they examine the effects of educational interventions in actual classrooms while the interventions are being implemented. As results are obtained and analyzed, the intervention is changed and continuously re-evaluated (Brown, 1992).

Cobb, Confrey, diSessa, Lehrer, and Schauble (2003) identified five overarching features of design experiments:

1. The purpose of design experiments is to develop theories about learning (including how learning is supported).
2. Design experiments involve an intervention, or the introduction of a new instructional technique.
3. In design experiments, researchers attempt to develop new theoretical perspectives, but also must test and refine their theories along the way.
4. Design experiments have iterative designs; as theories change during the study, the design of the study must be revised and altered accordingly.
5. The theories that are developed in design experiments should affect future instruction.

An example of a design experiment might be a study of a new curriculum designed to teach adolescents about HIV and pregnancy prevention. The curriculum might be introduced into the classroom setting; then, after initial presentation of the first few units, the researchers might collect data and then make some alterations to the next units, based on those data. This process can continue until the curriculum is substantially improved.

It is important to note that in design experiments, the changes in instruction that occur across iterations are often confounded with greater teacher familiarity with the

approach as a whole. This can be problematic, because it hinders researchers' abilities to make causal inferences.

Microgenetic Research. In microgenetic research studies, the same individual is observed intensively over a long period of time; this could be for many weeks or even months. Data are collected in order to examine both large-scale and small-scale changes in learners' use of strategies over time (Kuhn, 1995). Data can be analyzed via either quantitative or qualitative methods, depending on the types of data that are collected.

As noted by Chinn (2006), most educational research using a microgenetic approach has examined learners' usage of cognitive strategies (e.g., problem solving). Microgenetic studies are time consuming and be expensive, but they also can provide researchers with rich and detailed information concerning cognitive processes in learners. An example of a microgenetic study would be an examination of a kindergartner's strategy usage in solving simple addition problems over a three-month period.

Single-Subject Research. In a single-subject study, there is only one participant. Researchers generally examine a variable at a baseline stage (prior to the start of an intervention), and then later examine how this variable changes at different time intervals, as an intervention is introduced. In single-subject research, control or comparison groups are not used. Researchers are particularly interested in whether or not patterns replicate over time within the same subject; in addition, researchers also examine whether or not similar patterns can be generated in new subjects.

Single-subject studies are particularly common in the special education literature, although this methodology can be used in other areas of educational research as well. An example of a single-subject study would be an examination of the effect of classical music on the ability of a learning-disabled child to solve single-digit addition problems. First, the child's baseline addition skills would be assessed; then, the student's skills in the presence of music would be measured. The music might then be alternately started and stopped several times, while the student's problem-solving skills are continuously assessed.

Action Research. Action research is research that is conducted by classroom teachers, examining their own practices. The goal of action research is to examine one's practices critically and then to make changes to those practices based on the results of the research. Action research can be conducted by a single teacher, or by a group of educators working together.

Ferrance (2000) summarizes five steps in action research. These include:

1. Identify the problem or question that is going to be investigated.
2. Gather data to help answer the driving question. Data can be collected in many forms (e.g., interviews with students, surveys, journals, video or audio tapes, samples of student work, etc.).
3. Interpret the data by critically examining all data sources, and identifying major themes.
4. Evaluate results; in particular, examine whether or not the research question has been answered.
5. Take next steps—develop additional research questions, or make changes to instructional methods.

Action research can improve instruction for students; in addition, it can empower teachers, since it is a tool that allows them to judge their own efforts and evaluate the outcomes of their practices.

STRENGTHS AND WEAKNESSES OF RESEARCH DESIGNS

Each of the aforementioned research designs has both strengths and weaknesses. Some of these differences are obvious but others are not. Table 1 presents some examples of the key strengths and weaknesses of the various research methodologies discussed in this entry. This is not an exhaustive list; rather, it is provided to demonstrate that each methodology is complex and has both pros and cons.

When researchers and consumers of research evaluate the strengths and weaknesses of various designs, there are many issues to consider. Specifically, there are several key questions that can serve as a framework for evaluating research designs. The main questions are discussed below.

The Research Question. The research question is by far the most important question to consider when selecting and evaluating a research design. In all educational studies, the major research question should be articulated before the methodology is selected; the appropriate methodology should then be chosen based on that question. Most social scientists agree that a preferred methodology should not be used as a framework to guide research.

For example, a large school district might want to know if high school students' foreign language pronunciation is better after two years of studying Spanish or two years of studying French. The research question might be: What is the relation between studying French versus studying Spanish, and foreign language pronunciation after two years of study?

The researcher then must decide which research design is the most appropriate to answer the specific research question. In this example, the researcher can easily eliminate several options. For example, an experiment would be

impossible, since students cannot be randomly assigned to Spanish or French classes. In addition, the researcher might decide that qualitative and microgenetic studies are inappropriate, since the researcher is not interested in the processes or developmental trends that occur over time. There are several other questions that the researcher must also address that will help to finalize the decision.

The Sample Being Studied. Researchers must consider the nature of their samples when selecting a methodology. This is an important question because some methodologies are challenging to implement with certain populations.

For example, most studies that use survey-based methodologies require the participants to be able to read the survey items. If the sample included young children, or individuals with impaired visual abilities, then this might preclude the use of a self-administered survey. In addition, if the researcher is studying a large sample, with more than 1000 participants, in many cases this would prohibit the investigator from implementing single-subject designs, since the sample is so large.

Resources Available to Do the Research. Many resources are needed to complete research studies. Novice researchers often do not realize the cost involved with educational studies. A college student doing a small study for a research methods course will certainly not have the same resources available as an experienced investigator with a multimillion dollar grant.

Resources involve more than money. Another important consideration is personnel. Some research methodologies require more personnel than others. For example, a microgenetic study might be carried out by one investigator who can focus on the progress of a few subjects. In contrast, a large experimental study that requires collection of large amounts of data from many participants will require many more personnel. Thus if fewer resources are available, a researcher might not be able to use the ideal methodology to conduct a study.

Time is another important resource that often affects the type of methodology that is chosen for a particular study. A design experiment that involves continuous evaluation of progress and setting of goals might be ideal if a researcher has enough time to devote to a long-term study. Some studies (e.g., longitudinal studies) take a long time to complete. Thus a researcher who is interested in examining developmental issues, but who does not have a lot of time and funding, might select a cross-sectional methodology instead.

The Intended Audience for the Research. Different audiences will benefit from different kinds of research studies. If the audience is practitioners, then action

research might be highly appropriate. First, teachers can be directly involved in action research studies; second, other educators might be more willing to accept the results obtained from one of their peers via action research than from unknown researchers.

Certain funding agencies might be interested in only funding some types of studies. For example, there is much debate among educational researchers about the advantages and disadvantages of using experimental designs in educational research; whereas many funding agencies encourage experimental studies, many educational researchers argue that sometimes, true experiments are difficult to implement in actual classroom settings.

Using Mixed Methods. Many educational issues are multifaceted and complex; consequently, often one single methodology will not yield all of the essential information that researchers desire. Given the strengths and weaknesses of the various designs, and the many decisions that researchers must make before choosing a methodology, a number of scholars in recent years have begun to use mixed methods in educational research. When researcher use mixed methods, they use a variety of different methodologies within the same study.

A mixed methods study is usually challenging; the researchers must be able to utilize multiple designs appropriately. Some mixed methods studies involve two or more methodologies being carried out simultaneously, whereas others involve a succession of different studies, all designed to answer one general research question.

An example is a study conducted by Turner and her colleagues (Turner et al., 2002). In that study, the researchers were interested in examining the relations between early adolescents' perceptions of the classroom environment and the students' use of avoidance strategies (e.g., avoidance of asking for help from the teacher) in math classrooms. The researchers realized that the use of multiple methods would help them to best answer their research question. Therefore, they conducted a study in which longitudinal survey data were collected from a sample of more than 1,000 students. The researchers also randomly selected nine classrooms in which they conducted observations. The final analysis of data included quantitative results from the surveys as well as qualitative results from detailed discourse analyses from the classrooms. Each source of data provided different types of information, which allowed the researchers to examine a variety of indicators of the use of avoidance strategies by students. The quantitative survey data allowed the researchers to examine the relations of both student characteristics (e.g., gender) and students' perceptions of classroom environments to the use of avoidance strategies; the observational data allowed the researchers to

examine the discourse patterns in classrooms with different types of learning environments.

In summary, research methodology is a complex topic. This entry has described some of the most basic issues in the research enterprise, some of the methods that educational researchers use in their work, and some of the complexities involved in deciding upon an appropriate methodology. Ultimately, the methodology that is chosen will be determined by the specific research question and by the resources that are available.

Most research studies have limitations, which often are related to the design of the study. Research can always be improved, and it is important for scholars engaged in educational research critically to evaluate their designs and to acknowledge the limitations of their studies. As new researchers replicate previous studies, they often will attempt to eliminate the design problems encountered by previous researchers. This is one of the most important ways in which educational researchers can continue to improve and enhance knowledge about teaching and learning.

RESISTANCE THEORY

School classrooms involve complex human and environmental interactions. The classroom-based cultural landscapes hold unique teacher-student and student-student interrelationships that can mirror socioeconomic experiences of the larger community. In all these relationships, human agency permeates teachers' and students' interactions. Students' interpretation of and their responses to classroom culture can have profound effects on their achievement. Belonging, cultural relatedness, and autonomy are some of many issues that play key roles in determining students' motivation to approach or resist participation in learning activities. Resistance theories, in particular, provide a unique description of the classroom culture by examining how students or teachers perceive and respond to cultural dominance. Generally, resistance involves actions that passively or actively oppose the dominant culture. These actions serve to preserve students' or teachers' (as the case may be) sense of autonomy and identity.

CULTURAL OPPOSITIONAL THEORY

John Ogbu and Signithia Fordham (Fordham, 1996; Fordham & Ogbu, 1986; Ogbu, 1991; Ogbu, 2003) propose a resistance theory that explores minority students' reactions to cultural dominance. Originating with John Ogbu, this theory explores how different ethnic groups respond to different cultural landscapes. Ogbu suggests that ethnic-minority groups in the United States fall into one of two categories: voluntary minorities or involuntary minorities. These categories matter in the interpretation of mainstream cultures. Voluntary minorities are those who came or whose ancestors came to the United States out of their own free will (e.g., Vietnamese, Irish). Involuntary minorities are those whose ancestors were brought to the United States by force (e.g., African Americans) or whose ancestors were forced into ethnic minority status by military force (e.g., Native Americans).

Ogbu posits that voluntary minorities hold positive beliefs about the dominant society and, as a result, are more likely to adopt the attitudes and practices of the dominant group. In contrast, involuntary minorities hold less positive beliefs about the dominant society. These groups, such as the African Americans and Native Americans, see the United States as taking away or compromising their civil liberties. Ogbu suggests that, for many involuntary minorities, adopting dominant attitudes or behaviors is perceived as supporting their oppression. These beliefs for involuntary minorities have been substantially investigated by Ogbu and Fordham (Fordham, 1996; Fordham & Ogbu, 1986; Ogbu, 1991; Ogbu, 2003). In school context, Ogbu's 1991 findings suggest that voluntary minorities have more positive attitudes toward schooling, teachers, and the curriculum. Whereas

Southeast Asian and Chinese students accepted greater responsibility for academic underachievement, involuntary minorities avoided responsibility and asserted blame on teachers and school administrators.

In addition to attitudes, Ogbu and Fordham argue that perspectives of involuntary minorities manifest themselves in "oppositional behavior." That is, involuntary minorities react according to their beliefs about the dominant culture by engaging in behaviors that is in opposition to it. To support this notion, Ogbu (2003) reports that, in school contexts, involuntary minorities are more likely to disengage in academic activities than voluntary minorities. Ogbu called such behavior the "norm of minimal effort." Ogbu also found that these behavioral norms to disengage from academic activities were reinforced by African Americans who label other African American students who pursue academic achievement as "acting white." Such labels reinforce the notion that participating in dominant institutions by involuntary minorities contributes to the power of the dominant culture. In other words, if one succumbs to participating in the institutions of the dominant culture, then one becomes a member of that culture.

Furthermore, it is common to hear the expression, "talking white," a similar label to "acting white," applied to African Americans who use standard English. Limiting standard English in school is an important oppositional behavior that resists the dominant school culture. Similarly, a study by Bryan Brown (2003) explored how minority students in a science class avoided using scientific terms during classroom discourse, thus continuing to oppose the standard curriculum and pedagogy. These oppositional behaviors can have significant negative results on students' achievement. Ogbu (2003) observed an interesting phenomenon among students who resisted succumbing to the dominant academic culture: These students, while believing that education can lead them to economic stability, also held beliefs that athletics and entertainment could also serve as pathways to similar, if not better economic outcome.

Finn (1999), while using Ogbu's notions to describe reasons for students' resistance, brings together research of other scholars to expand sociological reasons for students' resistance beyond resistance of involuntary minority communities. Finn synthesizes a body of research on resistance of students from working-class families (Anyon, 1981; Weis, 1990; Willis, 1977) to suggest that the mismatch between working-class students' goals and their teachers' goals creates a social environment that is reminiscent of the relationship between management and workers within a factory. Within such a relationship, the management's goals have to do with meeting production quotas whereas the workers' goals have to do with managing and lowering

the amount of work that is required while maintaining salaries that can support their families. Finn reports that in such work environments, workers often develop systems that slow down the productivity. Likewise, Finn makes the connection to working-class students who challenge their teachers, sometimes subversively, by developing mechanisms to lower the amount of required work. An example of such a mechanism is students' asking a series of relevant and irrelevant questions to waste class time.

Finn, then, makes an explicit connection between Ogbu's work on resistance of involuntary minorities and that of scholars who describe resistance of working-class students by describing the relationship between unions and management. Union members who are seen as not cooperating with the union and collaborating with management are often harassed by other union members. For example, workers who beat their quota are often called derogatory names, reminiscent of the "acting white" term that is described by Ogbu. Likewise, working-class students who are seen to increase the amount of work in the classroom are also alienated by their classmates. Such oppositional social structures are natural spawning grounds for oppositional identities that enable resistance to school work.

CRITIQUE OF OPPOSITIONAL THEORY

While Ogbu's notions are well known in the education research community, his ideas are not without critics. The first set of criticism comes from Solorzano and Dolores Delgado-Bernal (2001), who challenge Ogbu's theory by suggesting that Ogbu focuses on "self-defeating" resistance. They, instead, posit that resistance can also have transformative effects. In their reconceptualization of Ogbu's work, they argue that there are four main types of students' resistance. The first type of resistance focuses on opposition with no orientation or awareness of social justice or the dominant culture. During such resistance, students exhibit poor classroom behavior for the sake of disrupting classroom instructional activities. Another type of resistance is self-defeating resistance. As a part of this type of resistance, students engage in oppositional behaviors with no real goal for bringing about social justice, although they may have some notion about societal inequities. This is most similar to Ogbu's notions of oppositional behavior. The third type of resistance is labeled as the conformist resistance. These students are very much aware of social injustice but do not respond to these beliefs by their actions. These students adopt dominant behaviors, in spite of their knowledge about society and school contexts. Finally, Solorzano and Delgado-Bernal describe the final type of resistance, transformative resistance. These students see the world as unjust and engage in oppositional behavior to bring out social

justice. These behaviors may include students' working harder to disprove negative expectations about their academic abilities or to challenge poor and racist classroom curricula or pedagogy.

Interestingly, in addition to describing development of oppositional identities of working-class students, Finn (1999) also identifies transformative people who have the power to create educational environments. While he describes resistance from the perspective of differentiated goals for education between students and teachers, he also describes societal leaders as having the option to be transformative. Finn does not believe that education in which students unconditionally do the work that teachers assign is "powerful." He believes that students must participate in their own education and that educators should establish educational environments in which students have access to empower themselves. To this end, Finn draws on the work of Aronowitz and Giroux (1993) to describe three types of educators: hegemonic, critical, and transformative. Hegemonic educators work to maintain the status quo by recreating an educational environment that, in its own right, recreates the social classes of students. In such classrooms, working-class students attempt to lower their workload while middle-class students do all their assigned work and learn how to glean information from textbooks. Critical educators believe themselves to be free of bias and think that they provide the same education to all students, regardless of students' backgrounds, including ethnicity and socio-economic class. Nonetheless, critical educators maintain the status quo by not actively challenging it by empowering students to take control of their education. Transformative educators help their students actively resist societal hegemony and take the power of education into their control. This, of course, fits directly into Solorzano and Delgado-Bernal's 2001 notion of transformative resistance.

Research on resilience highlights this notion of transformative resistance. Researchers such as Hassinger and Plourde (2005) suggest that students adopt adaptive behaviors to disprove prevailing expectations or stereotypes. Solorzano and Delgado-Bernal (2001) describe how students engaged in resistance behavior in order to announce their opposition to California state policy limiting bilingual education. Their resistance was aimed at promoting, in their mind, social justice.

The work of Horvat and Lewis (2003) counters Ogbu's notions about the significance of the "acting white" label by suggesting two counter examples. First, they review literature that suggests that the behaviors associated with negatively labeling students who participate in academic pursuits reflect students' in-group/outgroup school hierarchies that are typical of teen-agers, regardless of ethnicity, similar to the description above of

working-class students resisting schoolwork. Second, Horvat and Lewis describe their own research in which they found that “acting white” was not a dominant force in African American female students’ academic decisions. They report that African American females who participated in their research navigated among diverse set of African American peers from various socioeconomic strata of society. This challenge to Fordham and Ogbu’s notions does not negate the phenomena of resistance, but it certainly complicates the occurrence of resistance among involuntary minorities.

IMPLICATIONS FOR CLASSROOMS AND TEACHERS

Research on resistance theory highlights the need for some students to actively engage in oppositional behaviors. This is a choice that they make and this choice may be based on awareness of the dominant culture and social injustice. The reasons for students’ resistance may be difficult for teachers to assess. Oppositional behaviors may be the result of peer cultural norms (Horvat & Lewis, 2003), disparate goals of students and teachers (Finn, 1999), or awareness of social injustice (Solorzano & Delgado-Bernal, 2001). In light of the latter two reasons, the teacher needs to facilitate students’ autonomy by allowing students to critique the curriculum and classroom pedagogy. Some researchers suggest that autonomy-supportive behaviors, such as permitting students’ opportunities to voice opinions and oppositions to classroom activities, promote engagement in and positive attitudes about the classroom (Assor et al., 2002).

Students who engage in oppositional behavior as a result of cultural norms, however, require a different set of responses from teachers. One solution comes from Freire’s 1993 notions regarding the pedagogy of the oppressed. While some students may resist standard curriculum as a tool designed to oppress them, teachers can use strategies that raise students’ awareness about societal inequities and provide tools by which students may combat social injustice.

Another task for teachers is to carefully examine what activities, behaviors, and artifacts are valued by the class culture and school administration. Oakes and Lipton (2003) suggests that some schools and teachers show what is important in schools by way of rewarding key behaviors or attitudes. For example, schools show that they value high grades by posting names of students with excellent academic achievement. For many schools, these students may be racially identifiable. Other talents or abilities that reflect more student diversity may not be highly valued by a school. Teachers and school communities should take a critical examination of what gets praised and rewarded, determine whether these values

favor one ethnicity over another, and search for activities that value and convey social justice.

Finally, Gloria Ladson Billings (1997; 1998; 2000) and Geneva Gay (2002; 2004; 2005) write extensively about teachers’ making their curriculum culturally relevant. They suggest that classrooms should be spaces in which students find a sense of belonging, in which students believe that their teachers understand them, and in which instructional activities reflect students’ experiences by building on their prior knowledge. In these classrooms, students should work with and not in opposition to the teachers because their experiences are a part of the classroom culture; there is a symbiotic relationship that supports and promotes positive learning experiences for students as well as teachers.

REWARDS

Every teacher in every classroom throughout the United States uses strategies to acknowledge and encourage appropriate social and academic behavior by their students. These strategies take many forms, some overt and dramatic (presentation of tokens or recognition at an assembly), others more subtle and embedded in natural activities (a smile, the organization of a successful academic effort). This process of encouraging appropriate behavior and how best to incorporate this process in education has been a major focus of both research and professional controversy. As a result, understanding the role and function of rewards is in the early 2000s a central concern for many educators.

Since 1898, when E. L. Thorndike (1874-1949) described the law of effect, educators and psychologists have noted that when a behavior is successful it is more likely to occur again in similar circumstances. The success of a behavior lies in the result, effect, or consequence that behavior has on the environment. The simple message is that the consequences of a behavior affect future performance of that behavior. If, following the contingent delivery of a consequence, a behavior becomes more likely in the future, then that consequence was reinforcing or rewarding. This basic idea has been among the most intensely studied and validated phenomena associated with human behavior. The use of rewards in education remains a controversy, not over the principles governing its function, but in part due to two issues: (a)

the precise definition of rewards, and (b) the perceived effect of rewards on intrinsic motivation.

DEFINING REWARDS

Rewards (or the more technical term, reinforcers) are defined as any contingently delivered consequence (e.g., event, activity, object) associated with an increase in the future likelihood of a behavior in similar situations. This definition presents many problems when used in natural contexts such as homes, schools, and communities. When applied in a rigorous and precise manner, the definition allows an object or event to be classified as a reward, or reinforcer, only after demonstration that (a) the object/event was delivered contingent upon the performance of a behavior, and (b) the behavior became more likely to occur under similar conditions in the future. In practice, teachers and parents seldom wait to see the effect of a consequence on future occurrences of the behavior. It is far more likely that a teacher will simply presume that she or he has provided rewards when praise is delivered following sharing or points are assigned for correct problem completion, or access to preferred toys follows work completion.

An important distinction here is that the technical definition of a reward (reinforcer) always adopts the perspective of the learner, not the intentions of the person delivering the reward. If the contingent delivery of a consequence resulted in increased likelihood of that behavior, then the consequence was a reward. If the consequence was a piece of preferred fruit, and the behavior increased, then the fruit was a reward; if the consequence was a sticker, and the behavior increased, then the sticker was a reward; if the consequence was a reprimand (which included adult attention), and the behavior increased, then the reprimand was a reward. It is the effect of the consequence on future behavior that determines if that consequence is a reward (reinforcer).

If a consequence does not lead to increased likelihood of the behavior, then it was not a reward, even if the person delivering the consequence had the best of intentions. If a teacher's praise for on-task working is followed by a reduction in level of being on-task, then the teacher's praise was not a functional reward (reinforcer). If the delivery of tokens for sharing on the playground does not lead to increased sharing, then the tokens were not a reward. From a technical perspective, rewards are defined by the effect they have on behavior, not on their intended desirability. In this way, an event, activity, or object can never be defined as a reward without connecting it to the behavior that was affected by contingent access to that event, activity, or object. Practically, teachers will deliver feedback and consequences that they presume are rewards. Those teachers with

technical knowledge, however, will always check the effect of that presumed reward on student behavior.

Understanding rewards is of special importance because teachers not only want desirable behavior to be rewarded, but they also want to avoid rewarding undesirable behavior. A reprimand, for example, may not have been intended to be a reward, but may still function in that capacity. One of the more common findings in schools is that teachers inadvertently reward inappropriate child behavior by attending to talking out or disruptive acts. Similarly being sent to the office may be rewarding to some students if it involves escaping from aversive or difficult work. If a behavior is contingently followed by (a) obtaining a desirable event/activity/object or (b) avoiding an aversive event/activity/object, then the behavior will become more likely to occur in similar situations in the future. Said differently, the behavior has been rewarded.

Rewards are important for both encouraging appropriate behavior and preventing the encouragement of inappropriate behavior. What the science of human behavior teaches, is that teachers should adopt the perspective of the learner when they plan how to select and deliver rewards. The following are some basic guidelines:

- Reward behavior not people. When rewards are provided be clear about the specific behavior that led to the reward.
- Include the learner in identification of possible rewards. Use consequences that are likely to be rewarding to the students.
- Use small rewards frequently, rather than large rewards infrequently.
- Embed rewards in the activity/behavior that is to be encouraged.
- Ensure that rewards closely follow the behavior that is to be encouraged.
- Try to reward quickly because doing so tends to be more effective than delaying the reward.
- Use rewards that are natural to the context, appropriate to the developmental age of the learner, and easy to administer.
- Use many different kinds of rewards (objects, activities, privileges, attention, natural consequences) rather than relying on one strategy or pattern.
- Use rewards more often than negative consequences. Students should experience at least five times the number of rewards as they do corrections or punishers.
- Avoid delivering rewards (even inadvertently) for problem behaviors.

THE IMPACT OF REWARDS ON INTRINSIC MOTIVATION

Some people wonder if the formal use of rewards in schools may result in children failing to develop intrinsic, or self-managed, motivation. Reading should be a behavior that becomes more frequent because the content of what is read is rewarding, not because a token or play period will follow reading. Sharing on the playground should occur because a child experiences personal satisfaction from behaving well, not because the child receives candy if she shares. Similarly, some people wonder if a teacher provides a reward to Child A for excellent math work, it will be a negative, or punishing, experience for Child B who did not receive a reward, tried just as hard, but did not get as many problems correct. These concerns were substantiated in research conducted in the 1970s (Deci, 1971; 1975; Lepper, Greene & Nisbett, 1973) and have led to strong recommendations against the formal use of praise and extrinsic rewards (e.g., tokens, food, activities, privileges) in schools (Deci, Koestner, & Ryan, 2001; Kohn, 1993; 1996). There is evidence that rewards can be used poorly. The primary errors involve (a) providing rewards without being clear about the behavior being rewarded, (b) inadvertently providing rewards for problem behavior, (c) providing large rewards and then suddenly (rather than gradually) withdrawing the rewards, and (d) providing rewards so infrequently that a child never builds the skill fluency needed to attain the natural benefit of a skill (e.g., does not learn to read fast enough or well enough to enjoy reading). These errors are worth considering and avoiding.

The concern that rewards damage the intrinsic motivation of students is less well supported by research. Most educators will agree that academic and social skills learned in schools should be maintained by natural consequence, not artificial rewards. Reading, math and play skills should not end when a teacher is no longer present to offer verbal praise, toys, or stickers. The rewards provided for the behavior of one student should not function as a punisher for all others. There is less agreement (and much less evidence) that the use of rewards in schools leads to these ill effects.

To address these concerns several scholars examined the full body of research literature and concluded that schools successfully employed the use of external rewards for decades (Slavin, 1997) and the use of rewards following appropriate behavior is directly related to both initial and durable academic and social success. Rewards are an effective, important, and functional part of any educational context and need not be detrimental to intrinsic motivation (Akin-Little, Eckert, Lovett, & Little, 2004; Cameron, Banko, & Pierce, 2001). Rewards are especially important for helping motivate a child to build early

competence (fluency) with reading, math, or social skills. Encouragement, guidance, and reward of appropriate approximations of successful behavior are helpful for students in building the skills that can then be sustained by the natural consequences from reading well, joining games with peers, or playing a musical instrument. Rewards also are important for building a predictable, positive social culture in a school. Schools with clearly defined behavioral expectations and formal strategies for acknowledging (rewarding) appropriate behavior are perceived as safer, more effective learning environments. The delivery of rewards is one overt way in which children learn that adults are serious about the social and academic goals they are teaching.

Understanding and using rewards is an essential skill for any educator. Selecting the right type, level, and form of rewards to encourage student behavior is a competence developed over time and is a hallmark of effective teaching.
